Southport.—At the last meeting of the Council it was decided to light London street, Chapel-street, and Eastbank-street by electricity, and a motion was submitted authorising an application for power to borrow £1,900.

Cape Electric Tramways.—This Company have declared an interim dividend of 5 per cent. net, which is payable at the offices of the Company, 55 and 56, Bishopsgate-street Within, E.C., on or after the 22nd inst., by presenting coupon No. 6.

Imperial Tramways Co.—Warrants have been posted to the shareholders of the Imperial Tramways Company, Limited, in payment of an interim dividend at the rate of 7½ per cent. per annum on the ordinary shares for the half year ended June 30 last.

Charing Cross and Strand Electricity Supply Corporation.—Letters of allotment of the new issue of 30,000 new preference shares of the Charing Cross and Strand Electricity Supply Corporation, Limited, were posted to the shareholders on the 14th inst.

Friswell's Automobile Palace Co.—This Company was formed on 1st inst. with a capital of £40,000 in £1 shares, the object being to adopt an agreement with Friswell, Limited, and to carry on the business of cycle and motorcar manufacturers, engineers, machinists, etc.

Wellingborough.—The Urban District Council intend to apply, on or before Dec. 21 next, for a provisional order under the Electric Lighting Acts of 1882 and 1888, authorising them to supply electricity for all public purposes throughout the urban district of Wellingborough.

Accident.—During the thunderstorm of Friday last, a labourer employed by the Liverpool Corporation tramways was changing tram horses in Robson-street, when an electric wire fell on his head. He was severely injured, and died the same night in Stanley Hospital.

New Malden.—The Electric Lighting Committee are consulting Mr. Warden-Stevens on the proposed street-lighting, and the surveyor has been instructed to purchase Ordnance maps and indicate on them the positions of the lamps, and to afford every assistance in forming an estimate.

Barnet.—The Electric Lighting Committee have informed the Urban District Council that on terms similar to those embodied in the existing agreement with the Council, they would supply electric light to the whole of Manor-road, Barnet Common Estate, and to Sebright and Calvert roads.

Pontypool.—At a meeting of a committee of the Urban District Council on Wednesday, the question whether the Council should now apply for an order from the Board of Trade to establish electric lighting outside the area of the Pontypool Electric Light and Power Company was considered.

Johnson Electro-Germicide Co.—This Company has been registered with a capital of £2,000 in £1 shares, the object being to adopt an agreement with C. M. Johnson for the acquisition of a patent for improved means of destroying disease germs, and of an electrical generating machine and apparatus.

Association Programme.—We have received from the American Electro-Therapeutic Association a programme of the tenth annual meeting of the association, to be held at the Academy of Medicine, Room 44, 17, West Forty-third-street, New York City. Various interesting papers dealing with electricity will be read.

Killarney.—The Urban Council have not come to any definite decision concerning the offer of the electric light company to instal and light some additional lamps for £69. 12s. 5d. If the contract be given for three years they will contribute one-third of the cost, and if a five years' contract they will pay half the cost.

Perth.—Communications between the Electric Lighting Committee of the Police Commissioners and the Caledonian Railway Company with reference to an installation of the electric light in the station have resulted in a report on the subject by Mr. Dunn, which is at present in the hands of Mr. Patrick, the general manager.

London Gazette.—An adjudication order has been made out *re* W. V. Scott, 1, Shaftesbury-road East, Hammersmith.—Mr. W. M. Richards, 52, Belvoir-street, Leicester, has been granted his release as trustee *re* W. A. Charles and J. S. Blackwell (trading as the Central Electrical and Engineering Company), 14 and 111, Churchgate, Leicester.

Huddersfield.—On Wednesday the Corporation passed a resolution in favour of the recommendation of the Electricity Committee, which was to apply to the Local Government Board for sanction to borrow £30,342 for telephone purposes, to be repaid within 25 years, and the plans of the borough electrical engineer for the same were approved.

Yeadon.—The District Council are still considering the electric lighting question. At the close of a recent conference it was decided to take a *plébiscite* of the householders in the compulsory area of supply for ascertaining the number of lights likely to be taken up at a charge of 5d. per unit, and then submit the facts to a ratepayers' meeting.

Hampstead.—At the last meeting of the Vestry Mr. Greenhill moved that application be made to the London County Council for sanction to borrow £28,498 in respect of electric lighting extensions. It was necessary, he said, to pass the resolution at once, in order that time should not be lost owing to the holidays. The motion was carried.

Soler Aluminium Parent Syndicate, Limited.—This Company has been registered with a capital of £60,000 in £1 shares, the object being to adopt and carry into effect an agreement expressed to be made between Sir E. J. Reed of the one part and this Company of the other part; primarily to manufacture, sell, and deal in aluminium and alloys thereof, etc.

Compagnie Internationale d'Electricite, Liege.—We are indebted to Mr. H. Pieper, the general manager of this Company, for a splendidly illustrated pamphlet describing the works of the Company at Liège, and their exhibit at Paris. Generators and motors form the principal of the business, but the Company also manufacture a special kind of automatic arc lamp (Pieper's patent).

Swansea.—The advisability of the Corporation doing their own wiring is being discussed, and the chairman of the Electric Committee has replied, to enquiries on the subject, that he is not certain whether the agreement with the Free Wiring Company is executed, but, if not, he will gladly have the question discussed by the Council, as he is willing and anxious to assist consumers in every way.

Hull.—At a recent special and private meeting of the Electric Lighting Committee the electrical engineer reported that Messrs. Earles had made no further progress with the dynamos which they are making for the Corporation. The engineer was accordingly instructed to give Messrs. Earles the necessary notice to terminate the contract. The committee further resolved to notify this step to the sureties.

Aberdeen.—The estimates for the ensuing year for lighting are £11,800 against £8,650 expended last year, the increase being due to the proposed substitution of the electric light for gas in the central parts of the city for street-lighting, the streets to be thus lit being Union-terrace Bridge-street, Marischal street, Castle-street, Stirling-street, Exchange street, and George-street as far as Kittybrewster.

Sheffield.—The Electric Light Committee's last report states, with reference to service connections, that the manager recommended that no charge be made for leading in services for electrical energy up to a distance of 30ft. from the distributing mains, and that over this distance only actual cost price be charged. It appears that the recent breakdown in the Corporation electric light depôt is more serious than it was thought at first, and it is hinted that an almost complete renovation of the plant will have to be faced.

Stock Exchange.—The Stock Exchange Committee have appointed Wednesday, Aug. 29, a special settling day in Babcock and Wilcox, Limited, further issue of 90,000 ordinary shares of £1 each, fully paid, Nos. 440 001 to 530,000, and have also ordered these securities to be quoted in the official list. The committee have further been asked to allow the British Columbia Electric Railway Company's further issue of 1,600 5 per cent. non cumulative preference shares of £10 each, fully paid, Nos. 37,001 to 38,600, to be quoted in the official list.

Kingston.—The following accounts have been published by the Corporation: Electric light revenue—receipts—sale of electricity, £4,732. 2s. 6d.; arc lamps transferred, £900; arc (special) ditto, £96. 15s.; incandescent ditto, £86. 12s. 6d.; meter rents, £142. 15s.; miscellaneous. £899. 1s. 1d.; overdrawn account, £382 13s. 7d.—total, £11,811. 17s. Expenditure—overdraft (last account), £364 7s. 2d; generation, £2,890. 19s. 6d.; lamps, £26 7s. 3d.; distribution, maintenance, and management, £733. 7s. 4d.; loans, £2 674 5s. 7d.; wages, £1,492. 4s. 4d.; balance in hand, £285 3s.—total, £11,811. 17s.

Cardiff.—At a special meeting of the Electrical Committee Mr. Appelbee reported that Mr. Oswald Stoll had notified that the new Empire would be opened shortly, and asked for terms for supply of electric light. In order to give the supply desired—continuous current—it would be necessary to obtain a motor-generator, and he suggested that the committee should obtain that machine. It was decided that Mr. Appelbee should work out terms and discuss them with Mr. Stoll. At the ordinary meeting of the Town Council held this week several members complained of the small illuminating power of the new electric lamps recently put up on Canton Bridge. At the same meeting application was made to run motorcars for the convenience of passengers between Blackweir and that town until the Council had established the electric trams, which was approved.

Societe Internationale des Electriciens.—The administrative committee of this body has decided to divide itself into six sections, each of which will meet once a month, except during the vacation, in view of discussing questions which are of interest to the society, such as reports, meetings, admission of members, experiments in the central laboratory, high-grade school of electricity, scientific, and industrial missions. The sections are the following: (1) Production and utilisation of electricity as a motive power, will meet the first Monday in the month, under the presidency of M. M. Leblanc. (2) Electric lighting, will meet the first Tuesday in the month; president, M. Bochet. (3) Electro-chemistry, electrometallurgy, accumulators, batteries, the first Wednesday in the month; president, M. D. Monnier. (4) Canalisation, distribution, lighting, traction, etc., the first Thursday in the month; president, M. Grosselin. (5) Telegraphy and telephony, the first Friday in the month; president, M. Abraham. (6) Physical research, electro physiology, instruments, and measures, the first Saturday in the month; president, M. Armagnat. This division is to be commended, as small committees meeting more frequently, and discussing the subjects which they are more directly acquainted with, are more likely to bear fruitful results than fewer meetings where all members attend and where subjects are discussed which only interest the few.

Digitized by Google

Waterloo with Seaforth.—The Urban District Council, having received a number of complaints about the inconvenience caused to users of the telephone by noises on the wires, have decided to address a memorial to the National Telephone Company, explaining the difficulties under which subscribers were labouring, and asking that till the wires were put under ground something might be done to minimise the noise.

Electromotion Corporation, Limited.—This Company has been registered with a capital of £50,000, in £1 shares, the objects being to acquire a concession granted, or about to be granted, by the town of Nova Friburgo for the establishment of a public or private service of electric lighting and certain land and property known as Coscatel de Pinel, and including the waterfall situate in the municipality of Nova Friburgo, in the State of Rio de Janeiro, Brazil, etc.

Alfreton.—The Urban District Council have decided that the electric lighting area to be mentioned in the provisional order should be the Alfreton Ward. Mr. S. Johnson, the engineer (Mr. Barnes), and the surveyor are to inspect the district and settle as to the streets where private consumers are unlikely to be obtained, in which case it is suggested that such streets be struck out of the map and the provisional order, except for street-lighting purposes. In these streets a street-lighting cable only will be laid down.

Walsall.—Subject to the approval of the Local Government Board being obtained, and to the electric lighting undertaking paying to the gas undertaking an annual rent of £115, the Town Council will appropriate, for the purpose of the electric generating station, certain lands forming part of the site of the Wolverhampton-street gasworks. Application is to be made to the Local Government Board for their appropriation of the lands above mentioned for the purposes of the electric lighting undertaking.

West Highlands.—There is some talk of reviving the West Highland water-power scheme for the generating of electric power. The proposal under consideration is to trap the waters of Loch Erichd and convey them across country for a distance of 20 miles to the head of Loch Loven, where a waterfall of 110ft. would be obtained, giving a power equivalent to 23,000 h.p. The scheme, according to the estimate, will cost 1½ millions sterling. It is probable that the scheme will be opposed by persons interested in the North of Scotland.

Ashton-under-Lyne.—Mr. Robert Hammond has been engaged to inspect and report on the whole of the Corporation's existing station plant. The demand indicator system of supply will be abolished at the end of the present quarter, and a uniform rate of 4½d. per unit charged from that time and until further notice for all electricity supplied to private consumers for lighting purposes. Messrs. Lacey, Clirehugh, and Sillar propose to report on the refuse destructor as soon as they have satisfied themselves that the best value possible had been obtained therefrom.

Penistone.—At last week's meeting of the Guardians a deputation from the Penistone and Thurlestone Urban District Councils attended with reference to the question of the electric lighting of the whole district. The Clerk stated that the reason why the deputation had been invited to attend was that the quality of gas was not at all satisfactory, and also that a notice had been served of an increase in the price of gas. Finally, it was resolved that Messrs. T. A. Hinchcliffe (Denby Dale) and Henry Kaye (Clayton West) should represent the Board, and act in conjunction with the District Council.

King's Lynn.—At last week's meeting of the Council the engineer reported that the total number of applications for supply amounted to 210, being an increase of seven during the month, and that there were 372 street lamps (in addition to the arcs), being an increase of six. It was agreed that a main be laid down when required for new applications on the Spread Eagle Estate, and it was stated that the Local Government Board had sanctioned the loan of £10,000 for extensions, with the exception of £20, representing the debt outstanding on the gable end of the engine-house, which would have to be pulled down.

"English Illustrated Magazine."—The August number, well got up and sprightly as usual, contains another instalment by Mr. H. Drummond; another by Mr. Hulme Beaman's, "Adventures of Archibald P. Batts, Millionaire"; and a number of special articles, notably: "Israel in London: How the Hebrew Lives in Whitechapel," by George A. Wade; "Pompeii Up to Date," by Frederick Dolman, with excellent illustrations from photographs of the newer finds; and a very amusing sketch by Mr. C. W. Mason, entitled "Sam Lung and his Claim in Klondike," where the wily John and the 'cute Yankee measure swords, much to the profit of the Celestial.

Electric Enterprise in the West of Scotland.—In reference to the paragraphs that have appeared as to a project for establishing generating stations for the supply of electric energy throughout the West of Scotland, the *Glasgow Herald* is informed that another large scheme of a similar and comprehensive character for the supply of electricity for manufacturing, lighting, and other purposes throughout the industrial districts round Glasgow has been in preparation for a long time past, and is now matured. This scheme is being promoted by a number of gentlemen influential in the various localities embraced, and a Bill for the necessary parliamentary sanction will be introduced next session. The agents are Messrs. Maclay, Murray, and Spens, Glasgow.

Boiler Record Book.—The National Boiler and General Insurance Company, Limited (head offices, 22, St. Ann's-square, Manchester), are publishing a boiler record book, which will be found very useful by steam users, as by its means they will be able to maintain a concise and simple record of the important matters relating to their boilers. The information to be tabulated is classified under the following headings: number of boiler; year; dates of internal cleaning; dates of external flue cleaning; dates of thorough inspection; dates and particulars of special baring of brickwork or covering; repairs (if any) suggested in report; nature and extent of repairs carried out after suggestions in reports, or at any time; dates and particulars of overhaul of or substitution of fittings; general remarks.

Commercial Information Office.—We are informed that the Royal Commission at Paris has instituted a commercial information office for the use, without charge, of British exhibitors, visitors, and members of congresses. There is at the disposal of English members who may be attending congresses a spacious room where they can meet and discuss. This office is situated on the Quai d'Orsay, entrance by the side door on the east. A writing-room is provided for the use of members of congresses, and information on trade matters will be given as far as possible. In the office will also be found a comprehensive set of customs tariffs, information as to transport by land and sea, books of reference, directories, etc. Letters and telegrams can also during the congress be addressed to members as follows: telegrams—care of "Britpav," Paris; letters—care of Commercial Information Office, British Royal Pavilion, Quai d'Orsay. The office will be open daily from 10 a.m. to 5 p.m.

Electric Cargo Cranes.—The Tees Union Shipping Company, Limited, have recently installed at their wharf at Middlesbrough three portable electric cargo-discharging cranes. These electric cranes are similar to those installed by the Southampton Dock and Harbour Board. They have a power of five tons, and have been constructed by Messrs. Stothert and Pitt, Limited, engineers, of Bath and London, their consulting electrical engineer being Mr. J. G. W. Aldridge, of Westminster-chambers, London, S.W. At the new goods shed at Aberdeen Harbour three electric cranes are to be fitted up on the roof to discharge goods from vessels into the upper storey. These cranes are considerably more economical than the hydraulic ones. The current consumed is in direct proportion to the load lifted, whereas the cylinder of the hydraulic has to be pumped full of water whether to lift a maximum load or an empty chain. Another great advantage is that all the cranes can be worked from a central station, and separate boilers and fires are no longer required. The cranes, too, are not affected by frost, as are the hydraulic cranes.

Southend.—At the last meeting of the Town Council the Light Railways and Electric Lighting Committee reported on the tenders received for carrying out the following work in connection with the electric tramways and electric lighting: (1) for the erection of generating station, car sheds, etc., at the London-road depôt; (2) for the permanent way, road bed, paving, and bonding; (3) for steel girder rails and fishplates; (4) for boilers, fittings, and boiler-house accessories (Section A); (5) for steam generators, travelling cranes, switchboards, etc. (Section B); (6) for tramway and lighting feeders, and distributors (Section C); (7) for overhead equipment (Section D); (8) for trucks and car equipments (Section E). Out of 88 tenders received the lowest was that by Messrs. Dutilh-Smith, McMillan, and Co., of 29, Great St. Helens-street, and 32, South-road, Philadelphia, U.S.A., who offered to carry out the whole of the work for £87,500, which is £100 less than the estimated amount of the borough engineer. To the above amount must be added £3,375 for car bodies and £1,000 expenses, making a total outlay of £91,876. The above tender was accepted, as already noted in our last issue, and it was agreed that the sum of £10,900 was the proportionate part in the expenditure chargeable to the electric lighting account. Application will be made to the Local Government Board for allowing these sums to be raised.

Iron and Steel Institute.—The programme of the Paris meeting of the institute, Sept. 18 21, which has just been issued, promises a more than usually interesting meeting. The president (Sir Williams Roberts-Austen, K.C.B.) will deliver a special address, and M. Pinget, the secretary of the French Association of Ironmasters, will read a paper on the general progress of the iron and steel industry in France; Prof. Bauerman (Ordnance College, Woolwich) will describe the iron and steel exhibits at the exhibition; Mr. J. E. Stead (a member of the council) will give the results of his micro-chemical researches on iron and phosphorus; Mr. Colby (Pennsylvania) will discourse on the American methods of testing iron and steel; Mr. Dory (Bilbao) will speak of the washing of iron ore in Spain, whence we derive our principal supplies; and Mr. L. Katona will describe the latest improvements in the rolling mills of Hungary; and Baron Jupiner will read a paper on the constitution of slags in Austria. Other papers will be read by Mr. E. F. S. Lange (Manchester), on a new method of producing high temperature, and by Mr. Melland and Mr. Waldron (Mason University College, Birmingham) on the action of aluminium on the carbon of cast iron. The members will be entertained by the French ironmasters, and visits will be made to St. Chamond, in the Loire, and to the great ironworks at Hyanges, Lorraine. A number of excursions are projected, and members desirous of being invited to take part in either of these excursions may obtain all particulars from the secretary of the institute.

Institution of Junior Engineers.—The members of the Institution of Junior Engineers, in continuation of their annual tour, visited several works on Tuesday in Newcastle and district. In the morning they saw the works of the Newcastle and District Electric Lighting Company, which divides with another company the lighting of Newcastle, and which owes much of its capacity to the inventive powers of the Hon. C. A. Parsons, president of the institution. It was explained that the works, when opened in January, 1890, had three Parsons turbo-electric generators of 75 kw. capacity each, and that more recently a 500-kw. turbo-

Digitized by Google

alternator had been erected—in fact, had it not been that the Parsons steam turbo-generator occupies so little space, and is so free from vibration that no foundation is required for the machinery, the site could not have been utilised for the works. The company has at present turbo-generators representing nearly 1,720 kw. fixed, and has provision for 3,200 kw. The members were afterwards entertained at luncheon by the president, who intimated that he would be unable to preside at the summer dinner of the members on Friday night owing to his having to be present at the trials of the "Viper" at Portsmouth. After luncheon the members visited the Elswick works of Armstrong, Whitworth, and Co., inspecting the engine shops, heavy gunshops, cast-iron foundry shops for hydraulic and electric fittings, ammunition and small quick-firing gunshops, torpedo-tube factory, and the shops in which gun-carriages, mountings, and cartridge-cases are made. In the evening the members visited the engineering department of the Durham College of Science, Newcastle, where Prof. Weighton holds the chair of engineering.—*The Times.*

Glasgow.—The committee on electricity have submitted to the Corporation the eighth annual report and balance-sheet of the Corporation electricity undertaking, which embraces the year from June 1, 1899, to May 31, 1900, for the particulars of which we are indebted to the *Glasgow Herald*. The gross revenue amounts to £59 762. 2s., and the gross (or working) expenditure to £34 999. 15s. 11d., to which is added depreciation written off capital £3,181. 10s. 11d., the balance carried to profit and loss account being £21,580. 15s. 2d., out of which the committee had to meet the following requirements: (1) interest on loans, £15,256. 0s. 7d.; (2) sinking fund, £6,285; leaving a balance of £39. 14s. 7d., which has been placed to the credit of the reserve fund. The committee regret that, owing to the large amount which has had to be paid as interest on money borrowed for new works during the past year, which are as yet unproductive, it has not been found possible to write off in the account now submitted so large an amount in respect of depreciation as was written off in the previous year. With references to the charges to be made for the supply of electrical energy during the year 1900-1901, the committee recommend that these should be as follows: (1) Under the demand indicator system—(1) where a quantity not exceeding the maximum demand for 365 hours in the 12 months (being an average of one hour per day) is used, 6d. per Board of Trade unit; (2) all current consumed over the above quantity at 100 volts pressure, 2½d. per Board of Trade unit; (3) all current consumed over the above quantity at 200 volts pressure, 2d. per Board of Trade unit; (4) all current consumed over the above quantity at 250 volts pressure, 1½d. per Board of Trade unit. (2) Under fixed charged system—(1) a fixed charge of 4s. 6d. per annum for each 8-c.p. (32-watt) lamp or its equivalent fixed in consumer's premises (or £7. 0s. 8d. per kilowatt) for 100 volts supplies; 4s. 4d. per 8-c.p. lamp fixed (or £6. 15s. 5d. per kilowatt for 200 volts supplies, and 4s. per 8-c.p. lamp fixed (or £6. 5s. per kilowatt) for 250 volts supplies, this charge being spread uniformly over the 12 months; (2) an additional charge for all current used as recorded on the meter at the rate of 1½d. per Board of Trade unit. (3) All consumers who take a supply for the equivalent of five hours or more per day for 365 days per annum, to be charged throughout at the rates of 2½d. per unit for 100-volt supplies, 2d. per unit for 200-volt supplies, and 1½d. per unit for 250-volt supplies. (4) That a special rate of 3d. per unit be charged for supply to churches. (5) That for domestic consumers only a uniform charge of 3½d. per unit for 250-volt consumers, and 4d. per unit for 100-volt and 200-volt consumers be made, without the use of the demand indicator. (6) That for motive power purposes only, subject to such conditions as it may be necessary to enforce for the proper protection of the Corporation, a uniform charge of 1½d. per unit for 250-volt consumers and 2d. per unit for 200-volt consumers be made, also without the use of the demand indicator. (Note.—The charges under heads 4, 5, and 6 have already been approved by the Corporation.) The quantity of electricity sold to private consumers during the past year was 3 788,795 units, as compared with 2,566,016 units during the previous year, being an increase of 47·65 per cent. The number of consumers on May 31, 1900, was 2,852, as compared with 1,858 at May 31, 1899, being an increase of 994, or 53·49 per cent., during the year. There were 162 consumers who consumed the equivalent of five hours or over per day of their maximum demand throughout the year. The number of motors in use and supplied off the Corporation mains as at May 31, 1900, was 212, as compared with 78 at May 31, 1899. The total number of arc lamps erected and in regular use in the streets as at May 31, 1900, was 265, as compared with 227 at the same date last year, and the quantity of electricity consumed for street-lighting was 461,874 units, as compared with 258 334 during the preceding year. During the year the buildings at Port Dundas have been practically completed as far as the first section is concerned, and the temporary wooden shed which had to be erected within the line of the main building has been removed for some months past. The amount of steam plant erected or in process of erection and nearing completion as at May 31, 1900, at Port-Dundas was nearly 7,000 h.p., being rather more than double the amount of plant (3,300 h.p.) previously fixed in the Waterloo-street station. There is, therefore, 4,500 h.p. extra available at Port-Dundas to meet the coming winter's load, as compared with the amount available last winter. In addition to this, the buildings at Pollokshaws-road station have been advanced to a stage nearing completion, and the erection of the boilers, engines, and dynamos to an aggregate of 2,200 h.p. is now being proceeded with. This will provide an additional 2,200 h.p. beyond that above indicated to meet the demand of the coming winter, and after the wants of Pollokshields and other parts of the south side area in which mains will be ready for supply have been met, a considerable amount will remain available for assistance on the north side of the river if required. A further extension of plant for Port-Dundas station of about 5.000 h.p. is on order, and this is expected to be in full operation before May 31 next. An arrangement has also been made to put in additional plant of 2,200 h.p. in the Pollokshaws-road station after the close of the Glasgow Exhibition of 1901. This plant, consisting of two engines and dynamos, is due for delivery at the exhibition in January, 1901, where it will be erected and used till the close of the exhibition. About 20 miles of new feeders and 20 miles of distributing mains have been laid during the past financial year upon the north side of the Clyde, and about seven miles of feeders and five miles of distributing mains have been laid on the south side of the river, in addition to what had been laid before May 31, 1899. These feeders and mains the committee confidently hope may be put in use by October of the present year. The undertaking of the Kelvinside Electricity Company, Limited, came into the hands of the Corporation in August, 1899, and the committee are now putting in about 1,000 h.p. of new plant to meet the rapidly-growing demand in the Hyndland district of Kelvinside and also in the Dowanhill district as far as Byres-road. There is a steadily-increasing demand within the area of the Kelvinside estate, but it should be specially noted that during the past year 81 new consumers have been connected to the mains in the new tenements on the Hyndland-road district alone and that this number is rapidly growing, as many as 22 having been added since May 31 last. At the close of the financial year (1899-1900) the electricity rents that were still outstanding amounted to £6,279. 19s. 9d., and at about the middle of July there had been recovered a sum of £3,965. 12s. 5d. There was thus still outstanding at that time the sum of £2,314. 7s. 4d.

PROVISIONAL PATENTS, 1900.

JULY 31.

13679. Improvements in holders for electrolytic incandescent lamps. Bernard Mervyn Drake, Eustace Graham Sheppard, and the Nernst Electric Light Company, Limited, 82, Victoria-street, Westminster, London.

13680. Improvements in series resistances for electrolytic lamps. Sylvester Legh Powell and the Nernst Electric Light Company, Limited, 82, Victoria-street, Westminster, London.

13692. Phonographic recorder. Thomas Alva Edison, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13693. Process of and apparatus for duplicating phonographic records, also applicable for other purposes. Thomas Alva Edison, 23, Southampton-buildings, Chancery lane, London. (Complete specification.)

13709. Improvements in and connected with index arrangement for telephone subscribers. Hermann Oppenheimer, 55, Redcross-street, Barbican, London. (Actiengesellschaft Mix und Genest, Germany.)

13720. Improvements in methods of operating dynamo-electric machines. The British Thomson-Houston Company, Limited. 83, Cannon-street, London. (Ernst J. Berg, United States) (Complete specification.)

13721. Improvements in systems of electric meter control. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles L. Perry, United States.) (Complete specification.)

13722. Improvements in contact devices chiefly designed for use in connection with electrical counting or recording devices. Alwyn Walter Staveley and Isaac Hardy Parsons, trading as Gent and Co., 4, South street, Finsbury, London.

13732. Improvements in electricity meters. William Morris Mordey and Guy Carey Fricker, 46, Lincoln's-inn-fields, London.

13751. A new or improved automatic device for the safe operation of electric conductors with or without guard wires. Conrado Sintas and Ernesto E. Schultz, 18, Buckingham-street, Strand, London. (Complete specification.)

13758. Improvements in incandescent electric safety lamps. Frederick Humphrey Hill, 298, South Lambeth-road, London.

13765. Improvements in automatic electric block systems for railroads. Judson Shoecraft and Charles Carroll Gardiner, 111, Hatton-garden, London. (Complete specification.)

AUGUST 1.

13786. Self acting charge and discharge indicator for accumulators and similar apparatuses. Heinrich Wilhelm Hellmann, 4, Wielandstrasse, Charlottenburg, Germany. (Complete specification.)

13805. Improvements in insulating supports for electrical conductors. Gilbert Wright and Christian Aalborg, Westinghouse-building, Norfolk-street Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Jan. 2, 1900, being date of application in United States.)

Digitized by Google

13810. Improvements in trolleys for electric traction having three wires for triphase currents. Alfred Bosshardt, 4, Corporation-street, Manchester. (Léon Gerard, Belgium.)

13811. Improvements relating to underground electric conduits. Hermann Hillischer, 45, Southampton-buildings, Chancery-lane, London.

13816. Improvements in or connected with storage batteries. Walter Osmond Rooper, 115, Cannon street, London. (Complete specification.)

13820. Improvements in or relating to starting switches and automatic controllers of electromotors. Ernest Francis Moy and Percy Henry Bastie, 37, Essex-street, Strand, London.

13822. Improvements in alternating-current electromotors. Frank Michael Lewis, Norfolk House, Norfolk-street, Strand, London.

AUGUST 2

13839. Improvements in glow bodies and heaters for electrolytic incandescent lamps. Bernard Mervyn Drake and the Nernst Electric Light Company, Limited, 82, Victoria-street, Westminster, London.

13860. Improvements in controllers for electric motors. Thomas Steel Perkins, Westinghouse building, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Jan. 13, 1900, being date of application in United States.)

13873. Improvements in electric switches. George Herbert Whittingham, 52, Chancery-lane, London. (Complete specification.)

13874. Improvements in automatic circuit controllers. George Herbert Whittingham, 52, Chancery-lane, London. (Complete specification.)

13892. Process for the production of heating bodies for exciting electrical incandescence bodies made of second-class conductors. Victor Isidor Feeny, 60, Queen Victoria-street, London. (Allgemeine Elektricitäts-Gesellschaft, Germany.) (Complete specification.)

13901. Improvements in electrical demand indicators. John Reid Dick and the Reason Manufacturing Company, Limited, Norfolk House, Victoria-embankment, London. (Partly by Arthur Wright, on the high seas.)

AUGUST 3.

13951. Improvements relating to electric muffles or furnaces. Julius Weiss, 45, Southampton-buildings, Chancery-lane, London.

13962. Improvements in electric signal registering systems. Christian Albert Jensen, 77, Chancery-lane, London. (The Yargae Signalphone Manufacturing Company, United States.)

13963. Improvements in and relating to cipher code systems for use in transmission of cable, telegraphic, and other forms of written messages. Elmer Francis Cassel, 77, Chancery-lane, London. (Complete specification.)

13966. Improvements in Roentgen-ray tubes. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Elihu Thomson, United States.) (Complete specification.)

13967. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edwin W. Rice, jun., United States.) (Complete specification.)

13968. Improvements in systems of electric motor control. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Albert G. Davis, United States.) (Complete specification.)

13969. Improvements in insulated electric conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William Le Roy Emmet, United States.) (Complete specification.)

13970. Improvements in armatures for dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

13971. Improvements in rectifiers for alternating electric currents. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Elihu Thomson, United States.) (Complete specification.)

13972. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Alexander D. Lunt, United States.) (Complete specification.)

13973. Improvements in insulated electric conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William Le Roy Emmet, United States.) (Complete specification.)

13974. Improvements in rail bonds for electric railroads. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Jesse R. Lovejoy, United States.) (Complete specification.)

13975. Improvements in systems for controlling electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles E. Barry, United States.) (Complete specification.)

13999. Improvements in arc lamps. Léon Bénard, 46, Lincoln's-inn-fields, London.

AUGUST 4.

14037. Improvements in or relating to electrical transmission gear for motorcars and other machinery. Henry Thomas Dawson and Henry Alfred Dawson, 18, Hertford-street, Coventry.

14053. A lightning protector for telephones. Charles Richard Cormac, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

14054. Improvements in indicators for electric bells and the like. Julius Sax and Co., Limited, and James Aird, 226, High Holborn, London. (Complete specification.)

14063. Improvements in and connected with combined switches and fuses. Gilbert Cecil Pillinger and Albert Vandam, 322, High Holborn, London.

14067. Apparatus for generating and utilising electric energy. William Speirs Simpson, 166, Fleet-street, London.

14069. Improvements in lightning arresters. William Lloyd Wise, 46, Lincoln's-inn-fields, London. (Actiengesellschaft Electricitätswerke, vorm. O. L. Kummer und Co., Dresden.) (Complete specification.)

AUGUST 7.

14086. Improvements in wireless or Hertzian telegraphy. Alfred Charles Brown, 129, Algernon-road, Lewisham, London.

14101. Improvements in coils or helices for electrical purposes. William George Heys, 70, Market-street, Manchester. (John Scott, Richard Varley, and James Chris Anderson, United States.) (Complete specification.)

14104. Improvements in electrodes for the use in electro-chemical processes. Otto Lauckner, 80, Watling-street, London. (Alfred Vogelsang, Germany.) (Complete specification.)

14121. Improvements in methods of and means for producing light. George Croydon Marks, 18, Southampton-buildings, Chancery-lane, London. (The General Electric Company, United States.) (Complete specification.)

14134. Improvements in or relating to electrical traction. Edward Joel Pennington, 111, Hatton-garden, London.

14139. Improvements relating to electric railway systems. William Burrage Purvis, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14164. A new or improved insulator. Heinrich Traun, 18, Buckingham-street, Strand, London.

AUGUST 8.

14170. A quick make and break switch for electrical purposes. Henry Herbert Hill, Swancot Cottage, London-road, Hampton, Middlesex.

14212. Improvements in or relating to electric furnaces. Alfred Julius Boult, 111, Hatton-garden, London. (The Union Carbide Company, United States.) (Complete specification.)

14215. Means of fixing electrical appliances to ceilings, walls, furniture, and the like. Johannes Körner, Paul Körner, and Eugen Mahla, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

14237. A safety device or fender for electric tramways or the like. Carl Zimmerman, 18, Buckingham-street, Strand, London.

AUGUST 9.

14248. An improved electrical replacement indicator. August Eckstein and Arthur Edwin Mitchell, Peel Works, Adelphi, Salford, Manchester.

14275. Improvements in and relating to electro-chemical or copying telegraphs. George Cecil Dymond, 6, Lord-street, Liverpool. (The Kopier-Telegraph Gesellschaft mit beschränkter Haftung, Germany.) (Complete specification.)

14281. Improvements in telegraphy by means of alternating currents and imperfect contacts. Gustave Ferrié, 4, South-street, Finsbury, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Jan. 9, 1900, being date of application in France.) (Complete specification.)

14288. Improvements in electromagnetic apparatus for jacquards. Jan Szczepanik and Ludwig Kleinberg, 46, Lincoln's-inn fields, London.

14289. Improvements in electric switches. Arthur William Bundy Pearson, 72, Cannon-street, London. (Complete specification.)

AUGUST 10.

14324. Improvement in arc lamps. Frederick William Smith, Alfred John Smith, and Wallace James Lambert Sandy, 8, Clerkenwell-green, London.

14337. An electric releasing apparatus for pneumatic pressure brakes. August Brüggemann and Deutsche Waffen und Munitionsfabriken, 53, Chancery-lane, London.

15354. Improvement in magnetic separating apparatus. The Edison Ore-Milling Syndicate, Limited, 188, Fleet-street, London. (Thomas Alva Edison, United States.)

14355. Improvement in magnetic separating apparatus. The Edison Ore-Milling Syndicate, Limited, 188, Fleet-street, London. (Thomas Alva Edison, United States.)

14367. Improvements in electrical contact apparatus. Koloman de Kandó, 18, Buckingham-street, Strand, London.

AUGUST 11.

14373. Improvements in and connected with electrical fuse boards. Henry Oliver Farrell, 16, Kensington-road, Chorlton-cum-Hardy, Manchester.

14383. Improvements in or relating to electrical ignition devices for explosion motors having two or more cylinders. Edmund Woodward Lewis, 18, Hertford-street, Coventry.

14384. Improvements relating to rail points and overhead switches in electric tramways. William Carter and James Bowrey, Lloyds Bank-buildings, Bristol.

14409. Improvements in electric meters. Jesse Harris, 52, Chancery-lane, London. (Complete specification.)

14420. Improvements in combined electric meters and demand indicators. James Grieve Lorrain, Norfolk House, Victoria-embankment, London. (Arthur Wright, at present on the high seas.)

14422. Improvements in switches and apparatus for use in starting and controlling electric motors. Arthur Henry Adams, 11, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Sept. 1.

1899.

15816. Electromagnetic rail brakes. Wilde.

15882. Apparatus for operating two or more electrical regulating switches or resistance devices together or separately. Lucas.

16083. Controlling devices for electric currents. Cuénod.

16199. Switches for high voltage. Oppenheimer. (Actien-gesellschaft Mix und Genest.)

16267. Electrical apparatus for sorting articles according to one of their dimensions. Lock and Milner.

16293. Manufacture of leaden plates for secondary batteries or accumulators, and in moulds and tools to be employed in such manufacture. Davies.

16395. Arrangement for controlling electric elevators. Wahlström.

17815. Direct-acting electric generators and directly-driven electric compressors for air or other gases. Atkinson.

19090. Electric arc lamps. Wilby.

19261. Means for electrically rewinding clock or similar mechanism. British Thomson-Houston Company, Limited, and Holden.

19941. Electric tramcars with overhead collectors. Pick.

20145. Combination electric light fittings. Sevenoakes.

20316. Troughs for electric cables. Sykes.

1900.

1680. Picking up electric current sent from a generating station by a railway car and returning it. Sayer.

7814. Boiling and vaporising fluids by electricity. Sayer.

11120. Ploughs for conduit electric railway cars. Gottsberger. (Date applied for under International Convention, June 4, 1900.)

12018. Electric propulsion for motor road vehicles. Ryan.

12537. Electric accumulator plates. Ribbe.

NOTES.

A New Lamp.—According to *La Réforme*, a new form of electric incandescent lamp has been produced at the works of Messrs. Wrede and Jungblatt in Menin and Jemappes (Mons), which tests made at the municipal electricity works, Brussels, proved to consume 40 per cent. less energy than the ordinary type of incandescent lamp. The lamp, it is further stated, may be used without any special holder.

Electric Lighting in Greece.—The Hellenic Electric Society of Athens, which has already obtained concessions for lighting several towns in Greece, has just obtained a concession to light the district of Euripe in that country. The company for this purpose propose to use the canal of Euripe, by which turbines are to be driven. Failing the success of such an installation, the electrical machines are to be driven by means of gas-engines.

Cablegrams by Telephone. — The Postmaster-General has given his sanction to an agreement made between himself, the various cable companies, and the National Telephone Company, whereby Liverpool merchants will be allowed to have transmitted over the wires of the National Telephone Company any cable messages which arrive for them after business hours. This concession has been gained through the exertions of the Liverpool Chamber of Commerce, and the facilities will be given as soon as the formal deed now in preparation has been completed.

Gas Journals Please Note.—The following extract from a sermon on "Burden Bearing," delivered by the Rev. W. Muzzel at St. Paul's, Withington, will be of interest to our gas contemporaries. In this sermon the Rector said that "Nature was often made to share our burdens, and he wished the people of that church would assist Nature by illuminating the place with the electric light, so that their lives might be spared for a few years, as God intended them to be spared, instead of running the risk of being poisoned by having to breathe (especially in the close, warm weather) the vitiated and poisonous atmosphere caused by bad gas."

Electric Treatment for Lead-Poisoning.—The North Staffordshire Infirmary is now to be fully equipped with electrical apparatus of the most modern description for an extensive investigation on the treatment of lead-poisoning by electricity. The necessary money to provide this equipment has been subscribed principally through the interest of the Duchess of Sutherland, who commenced the movement at a drawing-room meeting, at which the present results obtained by the electrical treatment of workpeople affected by lead-poisoning were described. The electrical equipment at the infirmary in question will, besides electric baths, include a complete set of X-ray apparatus and an electric cautery for surgical work.

The Time-Limit Lamp.—We gather from the columns of the *Electrical Review* of New York that a German firm has recently placed on the market a type of incandescent lamp which can be made to automatically extinguish itself after a given number of hours' burning. The way this is effected is as follows: In the base of the lamp is fixed a copper tube containing a central part of copper wire and filled with a solution of sulphate of copper. A current is arranged to pass through this solution from the wire to the tube, so that a continued electrolytic solution of the wire takes place. As soon as the wire is all dissolved, the circuit is broken and the lamp goes out. The size and length of the wire may be set for any given number of hours, and the lamp thus becomes automatic in its action. We should have thought a more easy way of effecting the same result would have been to have made the gas given off in a voltameter actuate by pressure a mercury switch against a hydrostatic head.

North-East Coast Institution.—We have received a copy of the *Transactions* of the above Institution of Engineers and Shipbuilders, which is issued in August this year. It contains the proceedings of the seventh and eighth general meetings of the institution, in which the following papers were discussed: "The British Naval Engineer, and his Present Position and Influence on our Sea Power," by Mr. B. B. Morison, and "The Training of Young Engineers," by Mr. W. C. Borrowman. There is also in this volume the adjourned discussion on Mr. W. H. Atherston's paper on "The Fouling of Ships." The volume is of exceptional interest in view of the first-mentioned contributions to the *Transactions* of the institution.

Electric Lighting in Toronto.—The city engineer of Toronto has prepared extensive estimates for the buildings and machinery of a municipal electric lighting station for that city. He makes the total cost come out at £190,000. An arc lighting plant to supply 1,350 arc lamps through the streets in the town would cost a further sum of £60,000 if overhead wires are allowed, or £102,000 if the mains are laid underground. The engineer estimates that the cost of running these arc lamps, including interest and depreciation, would be about £12. 12s. per arc lamp per annum if the wires are overhead, and £14 per arc lamp per annum with underground wires. We trust that the municipal scheme will go through at Toronto, and that the work will be given out amongst Canadian firms, who have proved themselves well to the fore in electrical matters.

Telegraphic Interference.—The Government of the Argentine Republic is about to connect Buenos Ayres with Rosario by an underground cable, the length of which will be approximately 150 miles. The need for this cable is said to arise from the continued interruption in the land line service. Amongst the causes of these interruptions it is said that small spiders have played a considerable part. These insects abound in the district, and have used the telegraph wires as the foundations for their nets. Their cobwebs connecting the various wires do not interfere with the signalling on fine days, but after dew or rain has accumulated upon them they form almost a short-circuit between the conductors. The most annoying feature in connection with the variable resistance between the conductors so caused is that it is almost impossible to predict what state the line will be in at any particular time. The consequent interference with the signalling has resulted in the submarine cable project above referred to.

The New Alaskan Cable.—This cable, which is to connect St. Michael to Unalaklik and also to Cape Nome, is to be laid, all being well, during the present week. The first section of this cable is 55 miles long, the Cape Nome section is 132 miles long. In each case the core consists of $^{7}/_{24}$ wire insulated with a cover of rubber $\frac{1}{64}$in. in thickness. Over this is laid kerite up to a diameter of $\frac{3}{32}$in., and then a layer of tape; over this is built up a serving of three-ply tarred jute to an outside diameter sufficient to receive an armour of 16 No. 12 B. & S. galvanised steel wires. Over the armour is laid two reversed layers of three-ply tarred jute. Before armouring, the cable was subjected to a test of 5,000 volts alternating between core and the surrounding water, while an insulation resistance of 800 megohms per mile had to be obtained on every section. This is said to be the longest submarine cable manufactured by an American firm, the order being placed with Mr. W. R. Brixey, of New York. It is hoped

Digitized by Google

that the cables will be laid and ready for traffic by the 6th prox.

The City and Guilds Exhibition.—The programme of the technical examinations of the City and Guilds of London Institute for the advancement of technical education for the session 1900 to 1901 has reached us. We note that the examiners for the ensuing year will be as follows: in telegraphy and telephoning, Mr. J. Gavey; in electric light and power distribution, Prof. W. E. Ayrton, F.R.S., and Mr. W. B. Sayers, M.I.E.E.; in electro-plating and deposition, Prof. W. G. McMillan. In mechanical engineering the two examiners are Prof. Hudson Beare, M.I.C.E., and Prof. W. E. Dalby, M.I.C.E. The policy of the institute in making frequent changes in the *personnel* of their examiners is one that is to be highly recommended. If one has the same examiner year by year the questions are very apt to become stereotyped, and the various teachers throughout the country can then prepare their students by cramming them for the stereotyped questions. When the examiner is changed frequently, and is also selected from the highest ranks of the profession, as is the case with the City and Guilds of London Institute, only those teachers who really instruct their students in the groundwork of the profession are able to score in the examinations.

High-Voltage Trolley.—The following is an abstract of an article by Mr. Walter Reichel, contributed to the *Elektrotechnische Zeitschrift*, on some experiments made since 1898 by Messrs. Siemens and Halske, of Berlin, on high-voltage trolley working. The object of the experimental line was to determine if polyphase transmission at 10,000 volts enabled current to be taken off overhead wires by means of sliding contacts and reduced by transformers on the motorcars to a lower voltage for supply to the polyphase motors. The principal results of these trials are that it was proven to be feasible to take the currents off by sliding contacts at 10,000 volts and at speeds up to 37 miles an hour. It is well known that the ordinary under-running trolley wheel does not maintain uniform contact with the trolley wire at speeds above 25 miles per hour. The design of a sliding contact practical for higher speeds was, therefore, the main object of the experiments. The officials of the villages where the trial line was erected required a system of safety wires to be drawn below the trolley wires, in order to prevent an accident in case a wire should break; therefore, a sliding contact along the underside of the trolley wire could not be tried. Two other systems were tried: sliding contacts making contact with the upper side of the trolley wire, and lateral sliding contacts. The latter, which are shown in Fig. 4, proved to be the better. Trials were made with three line potentials—750, 2,000, and 10,000 volts—and at various speeds up to 37 miles an hour. The sliding contacts were found to work better at 10,000 volts than at a lower voltage, and proved to be entirely practical for the purpose. We are indebted for the abstract to the *American Electrician*.

Tramway Brakes.—The New York State Board of Railway Commissioners has issued its report on the official tests it made recently on brakes for street cars. The Commission concluded their report by stating that while satisfactory results were obtained on the tests, there is still much room for improvement in brakes for tramcars. The Commission feel that the public tests made by them will result in still further improvements in this direction, or in the development of new inventions which will reduce the distance within which a car going at a certain speed can be stopped. The Commission proceeds to congratulate itself on having done all it is able to do to conduce to the use of better brakes on the majority of the roads in the State of New York. The best brake, as found by actual experiments on the tests referred to above, was found to be that of the Electrical Selector and Signal Company. This brake is of the electric type. The next one in order is of the friction type, exhibited by the Peckham Brake and Wheel Company, while the third brake in order of merit was a hand-power one. After a careful consideration of the whole subject of brakes for electric tramcars, the Board has determined that, except in special cases where the liability to accident is very remote, the single chain and spindle hand brakes now generally used shall be replaced by more powerful brakes, made by one of the manufacturers recommended. As this list of manufacturers includes 14 or 15 firms supplying electric brakes, air brakes, friction brakes, and hand-power brakes, it will be seen that the Commissioners allow a wide range of personal selection to the managers of electric tramways in the State of New York. We gather from the general reading of the report, however, that the Commissioners have hardly the power possessed by our Board of Trade to enforce their recommendations.

The Speed of Warships.—We notice in the *Scientific American* an article congratulating the shipbuilding firm of Messrs. Cramps and Co. on the successful steam trials made on the Russian cruiser "Variag." According to the specification, the speed over a one-mile course was not to be accepted for this cruiser, but the Russian Government insisted on a steam and speed trial lasting over 12 consecutive hours. We understand that during a preliminary run made by the builders, the cruiser averaged 24·6 knots over an hour's run. On the official trial, which lasted only seven hours, owing to a slight breakdown in one of the high-pressure cylinders, a speed of 23·65 knots was attained. This result is most satisfactory for a cruiser of the tonnage of the "Variag," but is not at all on a par with the speed obtained on the "Viper." It will be remembered by our readers that on this ship, which is equipped with Parsons steam-turbines, a speed of 37·1 knots was obtained. Our contemporary goes on to criticise the proposal to use steam-turbines for ordinary marine work, and quotes Admiral Melville to the effect that the turbines consume such enormous quantities of steam. Comparisons between the steam-turbine and an ordinary reciprocating engine are rendered somewhat difficult, owing to the fact that one cannot indicate a steam-turbine in the same way as can be done with the reciprocating engine. It has been shown, however, by a number of steam consumption trials working against a brake, that with superheated steam a steam-turbine can be designed to give almost as economical results as a reciprocating steam-engine. For marine work the turbine has the further advantage that it has no oscillating parts to cause vibration in the ship. The vibration which is caused by the engines ordinarily used on board a ship is responsible for great waste of energy, and we shall not be surprised to find in the long run that the steam-turbine has commercial advantages on its side.

The Wannsee Railway.—As promised, some further particulars are duly given in the *Elektrotechnische Zeitschrift* in regard to the equipment of the Wannsee Railway, briefly referred to in our issue of the 17th inst. For the time being the number of electric trains run per diem is limited to six, but this number will eventually be increased to 30, the old service of steam-hauled trains being meanwhile retained, as previously mentioned. The distance traversed at each run amounts to 12 km., the object of the innovation being to obtain reliable data relative to the electrical haulage of trains with a view to the extensive introduction into Germany of electric traction for main-

Digitized by Google

line work. Messrs. Siemens and Halske have supplied the electrical equipment, and are conducting the experiments. The train supplied provides accommodation for 410 passengers, weighs 210 tons, and consists of 10 three-axle cars. The two third-class end cars, which carry the driving motors, differ in outward appearance from the other third-class cars only in that a glass-protected look-out is provided in place of the ordinary end partitions. The extreme end of each motorcar is provided with a driving platform and the necessary controlling apparatus and measuring instruments, besides the air-pump and boiler in connection with the Westinghouse brakes. The necessary propelling power is furnished by six series-wound motors, having an output of 150 h.p. each. These motors are coupled direct to the axles of the motorcars. The train is controlled from the forward car. The motors of one of the motorcars are permanently connected in parallel. At each side of the train are attached six collector shoes, which collect the necessary driving current from conductor rails laid parallel to the bearing rails in much the same manner, it would appear, as the current is collected by the electric train working the Kensington-Earl's Court section of the Metropolitan Railway.

A Thermo-Electric Motor.—We notice in a German contemporary an illustrated description of a proposed thermo-electric motor, designed by Mr. C. Mayer. The novelty in the apparatus is that it is proposed by it to generate electricity, and in the same machine to convert this electricity into mechanical motion. For this purpose a machine is built up, which is in section not unlike the old Gramme machine, with a disc armature. The field-magnet system is, however, exceedingly different, consisting of a field of the unipolar type, although the pole surface is not continuous. The disc armature is wound with short-circuited thermo-electric couples. The outside junction of this is subjected to heat from a gas-burner, the cold junction being at the inside of the core. In this way the inventor will get a current circulating round the core. The field-magnet system is also, by means of thermo-electric couples, short-circuited round the poles, and here again the external junction is heated by means of gas-burners, while the inner junctions are the cool ones. The arrangement of magnetic parts is such that the armature will then be inclined to move in the same way as the well-known Faraday disc. Air vanes on the armature will then draw air up past the internal junctions of both the exciting and armature thermo-electric couples, tending to keep the same cool. Although it is not shown in the drawings, we presume that the hot junctions will be screened from draught, so that the cooling action will only take place on the inner junctions. Nickel and iron are suggested in the article as the two metals to be used. It is proposed to regulate the power and speed of the machine by regulating the gas-burners, but another method of regulation—*i.e.*, of regulating the output by altering the current in the exciting circuit and taking the same from the external source—is suggested. No information is, however, given in our contemporary as to the effectiveness or otherwise of the apparatus.

The Cost of the Horse-Power Hour.—In their "Dictionnaire du Commerce" MM. Yves Guyot and A. Raffaldvich give interesting figures concerning the cost of small power for agricultural purposes, from which the following are taken: A man can exert a mean pull of 15·4lb. on a crank of 14in. radius, working eight hours a day, at a speed of 30 revolutions per minute. The daily wage of the man being 2s. 10d., the horse-power hour will cost 3s. 5d. Again, a horse weighing half a ton working a capstan 13ft. in radius exerts a mean pull of 121lb. at a speed of 180ft. per minute during eight hours. The cost of the horse's daily keep being 3s. 2½d., the cost of the horse-power hour will be 9½d. A bullock working under the same conditions exerts an effort of 143lb. at a speed of 133ft. per minute. The cost of the bullock's day's work being estimated at 2s. 10d., the cost of the horse-power hour will be 10¾d. A movable steam-engine of 3 h.p. to 8 h.p. working at high pressure without condensation, the price varying from £40 per horse-power for small powers to £30 per horse-power for mean powers, burns approximately 6·6lb. of coal per horse-power. The cost price of 1 h.p. produced by an engine of 6 h.p. working 10 hours daily during 150 days, comes out at 2$\frac{1}{10}$d. A fixed petroleum motor consumes about 0·5 litre to 0·8 litre (mean ¼ gallon) of mineral oil or paraffin per horse-power hour, and costs from £24 to £32 per horse-power, the locomobile motors costing slightly more; the cost price per hour for 1 h.p. can be estimated at 3½d. with petroleum and at 3½d. with paraffin. For a windmill developing a force of from ½ h.p. to 3 h.p., and costing from £40 to £120, the cost of the horse-power hour comes to just over 1d. With a waterwheel, the price of which, including masonry and installation, varies from £16 to £32 per horse-power, the cost of the horse-power hour comes to about ·33d., and for a turbine, the price of which varies, under the same conditions, from £12 to £20 per horse-power, the cost of power is about the same.

The Conductivities of Oxides.—In a contribution to the *Elektrotechnische Zeitschrift* Mr. J. Sohlman gives the results of some experiments which he has conducted in order to determine the relative conductivities of various oxides and oxide combinations when heated. The experiments showed that the conductivities of different oxides, and especially the temperature at which they commenced to be appreciably conductive, varied very considerably. Such oxides only as Mr. Sohlman deemed of possible utility for lamp filaments were experimented with. The oxides of beryllium, magnesium, and calcium proved to be very bad conductors even at high temperatures, requiring especially high temperatures in order to render them appreciably conductive. On the other hand, oxide of zinc showed better conductivity, its conductive stage being more readily attainable. Comparing the chemical properties of the oxides experimented with, it was found that with one exception those of relative bad conductivity possessed strong bases, while those of good conductivity were characterised by a more or less pronounced acidulous formation. The results obtained have led Mr. Sohlman to conclude that the conductivity of an oxide is a periodical function of the atomic weight of the particular element concerned, as is the case with many other physical properties of the elements and their combinations. The conductivities of the chemical combinations between oxides of different bases (salts) show a dependence upon the chemical properties of the constituent elements, though the ultimate conductivity generally varies very greatly from the conductivities of the component elements. It may also be observed that oxides which differ only very slightly in their bases may yield combinations which possess conductivities differing very considerably from those of the separate components. For instance, oxide of thorium in combination with oxide of lanthan, which has only a slightly stronger base, yields a substance which is a good conductor, while each of the oxides mentioned taken separately is a bad conductor.

The Manchester Corporation as a Trader.—The chairman of the Manchester Corporation Gas Committee has issued a memorandum dealing with the finances of his

Digitized by Google

department on the questionable policy of making large contributions to the rates out of the profits earned in that department. The statement reads as follows: "The gasworks of the city of Manchester were transferred by the Commissioners of Police to the Corporation in 1843 for the sum of £198,817. Since then there has been expended on the works £2,827,124, making a total of £3,025,941. During these 57 years the gross profit made out of the gas undertaking has been £5,227,086, so that if the Gas Committee during this period had been permitted to use their own profits for their own benefit, the whole of the gasworks would have now been paid for without having to borrow any money at all, and the ratepayers of to-day would have had a balance in hand of £2,201,145. Instead of this, the ratepayers have no balance, but owe £1,026,456, and have to pay nearly £40,000 a year for interest upon borrowed capital, which never need have been borrowed. What has been done with this profit of £5,227,086? The sum of £2,398,471 has been paid over for city improvements and in relief of the rates, £1,017,191 has been paid in the shape of sinking fund, £752,808 has been used to write down the value of the works as depreciation, and £1,058,616 has been paid for interest on borrowed capital. So that over a million of money has been given away when it ought to have been in the gas consumers' pockets. This brings up the total amount to £5,227,086." It will be clearly seen from the above that the state of affairs would have been very different if the gas had been supplied to the ratepayers without making a profit. While up to the present electric light undertakings cannot show quite such a good return, owing to the short length of time during which they have been at work, there is every indication that the electric lighting undertaking in Manchester could contribute largely to the general needs of the Corporation, but we trust that the Electric Lighting Committee will adopt the more enlightened policy of supplying electrical energy at prime cost.

Electricity as a By-Product.—We have referred before in our columns to a contribution read by Mr. H. T. Yaryan before the American Society of Mechanical Engineers on the supply of heat from an electrical station by means of exhaust steam heaters. We now have before us a more extended copy of the paper in question, which is printed in the *Journal of Electricity* of San Francisco. The author confines his attention to actual figures obtained by the Toledo Heating and Lighting Company for the six months ending Jan. 1, 1900. During this time the company supplied heat to 199 houses, and electric light to 450 houses. The actual receipts from the heating load were £1,980, while the electric lighting only brought in £1,813. The costs of operating were as follows: coal and other fuel, £1,008; salaries and wages, £566; repairs, stores, rates, and taxes, £379; making a total cost of £1,953. The system of distributing heat as practised at Toledo is as follows: Exhaust steam heaters receive the steam on its way from the engines and heat up circulating water to any desired temperature. This hot water is either passed direct to the consumers of heat, or else is delivered into a storage tank to be used later on in the day when the output of electricity is small, so that the exhaust steam is not sufficient for the heating load. The circulating system consists of two wrought-iron pipes laid side by side in the ground, and protected by planks with air-spaces between, the air acting as a heat insulator. About 8,550ft. of hot-water pipes have now been laid under the road, and it is estimated that the total loss by radiation from the mains is only from 15 to 20 per cent. of the heat used in the houses. In fact, the drop in the temperature between the hot water at the station and the farthest consumer is only 12deg. F., whereas the water used enters the houses at about 160deg. F. This heating system is in use for seven months in the year, and the company now propose to introduce a system of pipes to be used in the summer time to distribute brine chilled down below the freezing point. Mr. Yaryan estimates that when this is done the company will be amply remunerated by its income from the heating and refrigerating plants, while the electric lighting will be obtained as a by-product. We hope that in this case the income from the electric lighting will benefit the engineer who has so carefully laid out the system.

Institution of Junior Engineers.—The members of the Institution of Junior Engineers are this year holding their annual tour in the Newcastle-on-Tyne district. The selection of this district was somewhat natural, seeing that the Hon. C. A. Parsons is this year the president of the institution. Amongst the works they have visited were those of the Newcastle and District Electric Lighting Company, the plant of which is largely due to the inventive capacity of the Hon. C. A. Parsons. It was explained that the works, when opened in January, 1890, had three Parsons turbo-electric generators of 75 kw. capacity each, and that more recently a 500-kw. turbo-alternator had been erected—in fact, had it not been that the Parsons steam turbo-generator occupies so little space, and is so free from vibration that no foundation is required for the machinery, the site could not have been utilised for the works. The company has at present turbo-generators representing nearly 1,720 kw. fixed, and has provision for 3,200 kw. The members of the institution also visited the Elswick works of Armstrong, Whitworth, and Co., inspecting the engine shops, heavy gunshops, cast-iron foundry shops for hydraulic and electric fittings, ammunition and small quick-firing gunshops, torpedo-tube factory, and the shops in which gun-carriages, mountings, and cartridge-cases are made. Other places on the River Tyne and in the surrounding district were visited by the members, to whom a hearty welcome was extended by the Newcastle-on-Tyne Corporation. We notice that they also visited the Newcastle-on-Tyne Electric Supply Company's works, so that they were able to make a comparison between two stations running in the same town to supply electrical energy, the one equipped with steam-engines and the other with steam-turbines. At these latter works the supply is given on the single-phase alternating-current system, the pressure at the consumer's terminals being 100 volts. The generating pressure is 2,100, and the transmission to sub-station and house transformers is by means of rubber concentric cables drawn into iron pipes. The standard type of plant installed is Robey horizontal compound engines driving, by means of cotton ropes, Brush alternators. Steam is supplied by Lancashire boilers, working at a pressure of 120lb. per square inch. The total number of lamps supplied is the equivalent of 69,640 8-c.p. lamps. It was stated that large extensions were now taking place to afford a continuous-current supply; the plant being by Messrs. Belliss and Messrs. J. H. Holmes, and the cables by Messrs. Callenders, laid on their solid bitumen system.

Telephones in London.—Although the holiday season is now on, with a consequent diminution of traffic in the London streets, those unfortunate individuals who have not yet been away into the country, or the more unfortunate ones who have come back, are constantly reminded that the Post Office authorities are undertaking the construction of a new telephone system. A large number of the principal streets in the City are now in the hands of the various contractors to whom the

Digitized by Google

laying of the earthenware conduits to receive the telephone cables have been allotted, and we must do these contractors the credit of stating that they are proceeding with their work with the least possible delay. In spite of this the inconvenience to the public is great, and it is difficult to seek consolation in the thought that a perfect telephone system will be available in a year or two. The inconvenience is, of course, quite unavoidable, as overhead wires are out of the question, but we should like to be assured that as soon as Newgate-street, for instance, has been relaid that it will not be taken up again to receive the conduit wires which have to be laid down by the Charing Cross and Strand Electric Supply Corporation under their provisional order. We know of one case in which the Post Office authorities absolutely refused to work with an electric lighting company in simultaneously opening up the streets, although a large financial saving would have resulted. This saving is, however, a comparatively small matter compared to the financial value of the great inconvenience and delay which is caused to the general public by the double breaking up of the public thoroughfares. It is interesting while on the subject of telephones in London to see from the report of the past year of the Postmaster-General the progress of telephone business throughout the country. Thus the number of post offices open for trunk telephone business on March 31 last was 299, an increase of 13 in the year. The trunk lines in use consisted of approximately 68,657 miles of wire, and 7,250 miles of wire were in course of construction. Out of the sum of £2,300,000 authorised by Parliament for the purchase and development of the trunk system, the expenditure up to March 31, 1899, may be stated approximately at £1,531,209. The expenditure during the year was approximately £176,968. Contracts involving the expenditure of more than £500,000 have been made, and works necessary for the establishment of a Post Office exchange system in the London area are in progress. It is expected that the system in the City and in certain other important districts will be in working order early next year.

Paris Educational Awards.—Amongst the awards to English exhibitors granted in connection with the Paris Exhibition, we notice a long list in connection with education. For instance, in connection with technical education grand prizes have been awarded to the City and Guilds Institute examination department, to the London County Council, and to the Central School of Arts and Crafts, while the Educational Department of South Kensington has also received a grand prize. From our inspection of the exhibits of English institutions in the Paris Exhibition we are somewhat surprised at the number of gold, silver, and bronze medals which have been awarded to the various technical schools throughout the country. Our surprise is not due to the exhibits themselves being defective, but to the slipshod way in which these exhibits were arranged. In the first place, it would have been much more reasonable for the various technical colleges to have united under one committee in preparing a joint exhibit than for each college to prepare a distinctive exhibit. A committee of the kind we indicate above would thus have been able to supervise the arrangement of the exhibits, so that, while avoiding repetition, a clearer idea would have been given of the best methods of giving technical instruction in this country. With the present want of system in the arrangement we noticed something of this kind: One of the technical colleges was explaining by exhibits the manufacture of a tin teapot; the drawing which showed how to obtain the exact shapes in the flat of the various tin plates which had to be cut was framed and hung at one end of the exhibit. This drawing was surrounded by articles of needlework made at the same school. Elsewhere on the stand the tin plates themselves were on view, and further on again, surrounded by an exhibit of shoes, was the teapot made according to the drawings. While we are prepared to grant that the space allotted to the school was small, the exhibit as finally arranged was chaotic and almost useless. Again, in another exhibit of another technical school we saw a galvanometer made by a student which was not at all fit to be shown as an international exhibit. These faults in the arrangements of the exhibits were not to be found in the educational section devoted to the French nation, who, of course, had more room at their disposal. We are pleased to see that the educational systems in this country have been so honoured by the awards at the Paris Exhibition, but trust that these awards will not lead their recipients to think that they have nothing to learn in the art of imparting instruction.

Polyphase Motor Work.—In the August number of the *American Electrician* there is described what is said to be the largest isolated plant using induction motors in the world. This is a plant used by the Deering Harvester Company, of Chicago. The firm in question has a most extensive business, covering a wide range of manufacturing subjects, and up to 1898 its various workshops were all driven by isolated engines, working on to long countershafts. In that year the first experiments with electrical driving were commenced, with such success that there have been continuous additions ever since. The present extent of the installation may be gathered from the fact that already there are at work two machines of 1,100 kw. and one of 750 kw. Owing to the arrangement of the machinery, large motors have been used to drive the various departments rather than installing small motors to drive individual machines. Thus the size of motors used, of which there are 65, varies from 20 h.p. to 100 h.p. The frequency of the three-phase supply is 40 complete cycles per second, and the motors are constructed for six or eight pole, giving a speed of either 800 or 600 revolutions per minute. The pressure on the mains, which we take to be the voltage between any two wires of the three-phase system, is 600. A novel feature in this installation is that there are no starting resistances used in the rotors. Owing to the large amount of inflammable particles which are always flying about in the woodworking and hemp departments of the company, great care had to be taken to prevent fires, consequently a short-circuit rotor was used, and a liquid resistance is inserted in the main circuit when starting up the large motors. As an example of the capacity of this resistance to reduce the starting current, a 75-h.p. motor was started up on the water resistance against practically full load with a current of only 300 amperes per phase. This gave a drop of voltage of 75. If the motor was switched directly on to the mains 600 amperes passed through it, and the voltage fell from 600 volts to 475 volts. An interesting experiment was made at this factory of leaving all the motors in circuit and starting up the generators slowly. The field magnets of the generator were, of course, fully excited, and it was found in this way the whole of the motors could be conveniently run up to speed without taking any large current. The value of this property of induction motors will be very great in factory work, as there will be no need to operate the individual starting switches of the motors when closing down at meal times. If the main generator is shut down and slowly started after the interval, all motors in circuit will start up without any damage, just as though they were connected by gearing to the main engine.

THE ELECTRICAL ENGINEERS' CONFERENCE IN PARIS.

[BY OUR SPECIAL CORRESPONDENT.]

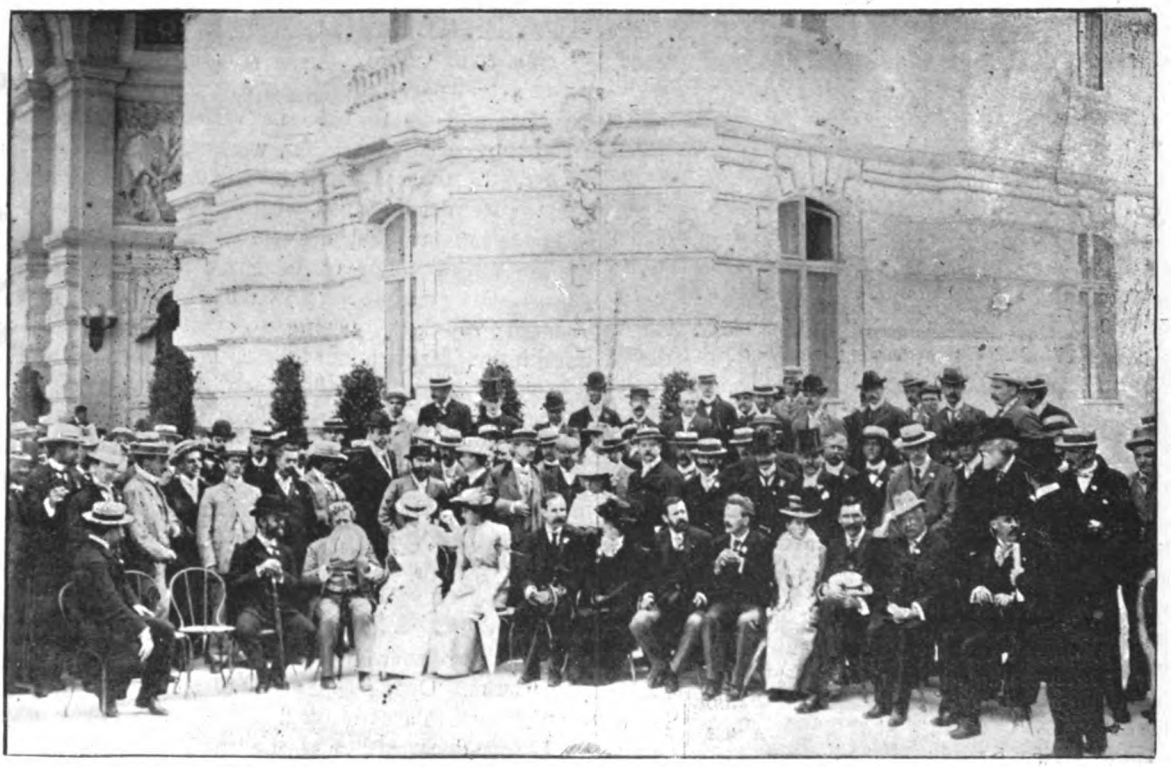
Those responsible for the combined meeting of the Institution of Electrical Engineers and of the American Institute of Electrical Engineers in Paris last week were well rewarded for their labours by the unqualified success of this interesting gathering, and it is probable that the success may even have exceeded their anticipations. In taking advantage of the Universal Exhibition they were certain of securing a good attendance of members, and in bringing the two bodies together, the subject under discussion was treated upon much broader lines and in a more interesting manner than could have otherwise been the case. It was, indeed, felt that the experiment had justified the holding of similar meetings in the future, but if this is to be done it is to be hoped that the conference will be extended over more than one sitting, for it is obviously impossible to thrash out a question, which may be discussed from several points of view, in the course of a couple of hours.

The meeting was held on the Thursday morning in the American Pavilion of the Exhibition, an imposing structure built in the Roman style and containing a large amphitheatre surrounded by tiers of galleries. Unfortunately, the building is not remarkable for its acoustic properties, with the result that those speakers who were not endowed with particularly vigorous lungs had to be invited to "speak up." The meeting was presided over by Prof. John Perry, F.R.S., president of the Institution of Electrical Engineers, and by Mr. Carl Hering, president of the American Institute of Electrical Engineers. There were upwards of 100 members present, including representatives of the electrical engineering industry not only from Great Britain and the United States, but also from France and Japan.

Mr. CARL HERING opened the proceedings by saying that there would be two presiding officers at that joint conference, and that Prof. Perry, as senior officer, would conduct the affairs of the meeting. He took the opportunity of thanking the members of the Institution of Electrical Engineers for the great pleasure they had given the American Institute in joining them in that international gathering. It was quite a venture on their part to hold a meeting so far away from home, but when they found how heartily the British engineers had joined them the success of their venture was at once assured. He was certain that all the members who were present, and a good many who were not, would hope that this first meeting would be the beginning of a series of similar meetings, and that the next gathering would be held in the United States. Mr. Hering then translated his address into French and German.

Prof. PERRY said that his remarks would be very brief. He could only say to the Americans who were now their hosts that their visit to England gave them very great happiness indeed. He thought that every Englishman who joined in the parties felt that it gave them more pleasure than even the Americans themselves expressed. There were no minutes to be read at this meeting, as it was the first of its kind, but minutes would be prepared, and, he hoped, read on a future occasion. He concluded by extending a cordial welcome to those present.

Prof. E. MASCART remarked that he must first of all address the Institution of Electrical Engineers and thank them for the honour they had conferred upon him in electing him vice-president. He was extremely touched by this mark of esteem on the part of the members of that body. In joining forces the two institutions of England and America had set a good example, and he hoped that it would be the forerunner of other meetings of this kind, which would include the electrical engineering societies of all the leading countries. They had been asked to go to the United States for the next conference. He would greatly desire to do so, for he had preserved a charming souvenir of the visit he paid to that country some years ago, but unfortunately his travelling days were now over. He thought, however, that a good many members would respond to the invitation, and as the result of the example now set by the two leading bodies many would no doubt go from England, France, Germany, and perhaps other countries. In the name of the French societies, he thanked them cordially for having selected Paris for the first meeting of the associated institutions.



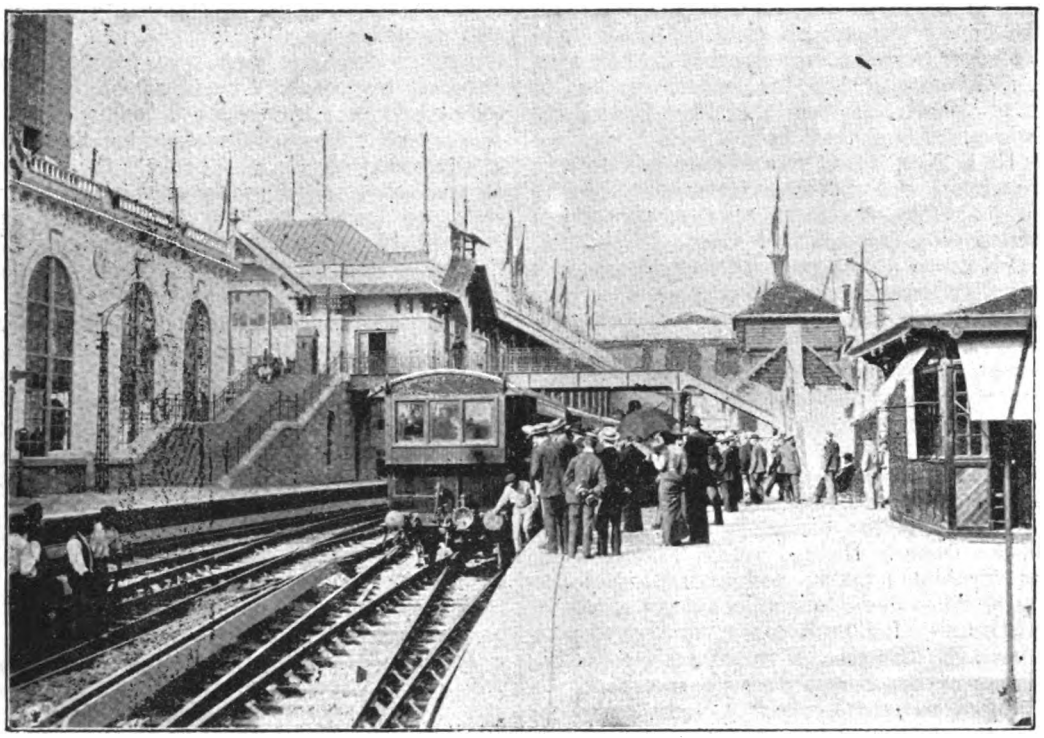
Group outside the American Pavilion, Paris.

Prof. PERRY announced that the subject for discussion was "The Relative Advantages of Alternate and Continuous Current for a General Supply of Electricity, especially with Regard to Interference with other Interests." He called upon Mr. S. Z. de Ferranti to open the discussion.

Mr. FERRANTI said that he was greatly honoured by being allowed to open the discussion at this most fortunate meeting. He called it "most fortunate" because they would agree with him that nothing could be better than that the American and English Associations of Electrical

Digitized by Google

Engineers should have a joint meeting. There was only one thing in his mind which was still better, and that was the holding of the meeting in Paris, and thus showing what a great tie really united them all, and how much more friendly their feelings were than was often supposed. The subject for discussion was left to the English association, and he could assure them that it was a matter of no little difficulty to decide upon what they should discuss. They might possibly think that the subject chosen was simply a revival of the old contention between alternating and continuous currents. He hoped, however, that it was no such thing. Matters had greatly changed since the days when the advocates of each of the two systems were, he might almost say, bitter enemies, and when it was thought that everything that was done by the other side was wrongly done. They now found that this was not the case, and that there were great merits and particular uses for both systems. But, as he said, things had changed, though not changed so much as was likely to be the case in the future. What they had to consider was, what electrical science would be 10 or 15 years hence. They knew what had already been done, but he thought that few of them, though it was their life's work, realised what electricity was going to grow to, and what a great and universal part it was going to play. In this light they must consider what were the best lines to be worked upon. It was no longer the small business it used to be. The small isolated systems had to be worked upon isolated plans, but it was now a question of utilising and transmitting big powers over large areas. With regard to the advisability and desirability of the systems of continuous current as against the alternating, many of them knew that he had consistently worked with alternating current, and they would appreciate that his knowledge of the other system was not what it should be as compared with the knowledge of those who had worked exclusively in that direction. In opening the discussion, he desired to dissociate from their minds what he had done in the field of electrical science. He put a few points before them to hear what the general opinion was upon this important subject. He believed that there were undoubtedly particular cases where the alternating or continuous current had its own application, but, looked at from a new point of view, the question that presented itself was, Which would be the possible system in the future? He said "possible," because many of them had had very serious experience with electrolytic effects which were produced by large volumes of continuous current, and he asked if, in the event of this system being developed and extended very considerably, it would be possible to satisfactorily preserve any metal work in the earth at all? They had not only to deal with the lead coverings of electric cables, but there were any amount of constructional ironwork, rails, gas-pipes, water-pipes, and all sorts of things, which were being laid down on an increasingly large scale every day in the streets all over the country. The amount of property invested underground in one or another of these forms was being continually multiplied, and the capital represented by these installations was reaching such a high figure that it became a serious question for them to consider, not only in the light of the present, but more especially of the future, as to the lines upon which they should go, and how best to protect this immense property, which might be injured by the work they were doing. Of course, alternating currents were not free from producing some harm, but the difference between the harm effected by the alternating and continuous currents was very great; and he thought that it required their most careful consideration and investigation to find out how they could diminish these troubles, or see whether it would not be necessary to employ the alternating current, which produced far less detrimental effects, and see how to overcome the disadvantages which were left with it. He hoped that a good many of those present would supply valuable information upon this subject, and after giving it their careful consideration would publish their views through the electrical Press, or else at another combined meeting of the two institutions. He trusted that the discussion upon this subject would save much trouble in the future, and prove of great service to the electrical industry at large.



Boarding the Electric Train, Champs de Mars Station, Paris.

Mr. ARNOLD, of Chicago, said that they had all heard that the man who invented alternating current was liable to be murdered on the spot, but after Mr. Ferranti's remarks he thought that they were on the right track after all. It would, perhaps, bring out a discussion upon the practices of the different countries if he briefly outlined the methods obtaining in the United States. There they started in the large cities with the direct-current system as advocated by Edison, and one day he read an opinion from Mr. Edison as to the advantages of the alternating and direct current. Mr. Edison said that the alternate current was inspired by the devil, and that no good would come out of it. Mr. Ferranti had proved to the contrary. They had started in their large cities with the direct-current system, and in small cities having a large area of distribution with the

Digitized by Google

alternating system. In the large cities the direct system was replacing the alternating system. In Providence they had replaced the alternating system with a direct current of 500 volts, and the same thing was taking place at St. Louis. He made this statement to show that the direct current was holding its own in the large cities, but he thought that the alternating current would be more generally used in the small towns and in the large cities for outlying work. As regarded electric lighting, there was not, so far as he was aware, any means of equalising the load which would allow of utilising the alternate current under certain conditions. Coming to railroad work, they started with a 500-volt system, and gradually increased it to 600 and 700 volts, and were now utilising it for the sections of roads adjacent to the station, and were serving the more distant sections with alternating current. He thought that this arrangement would be modified when the alternating current would predominate and the sub-station would be suppressed. Mr. Ferranti was working in this direction, and others were doing the same thing in the United States. He hoped and fully believed that their efforts would be attended with success.

Sir W. H. PREECE said that he felt in the same position as the blank leaf between the Old and New Testaments. He was there as a past-president of the Institute of English Electrical Engineers, but he was also honorary member of the Institute of Electrical Engineers of America. He therefore spoke in the blank-page capacity. He also held the position of never having compromised himself by associating himself either with the direct-current system or with the alternating-current system; but he had used one or the other when he thought that he could get advantages by so doing. He believed there were circumstances where the one was essential, and different circumstances where the other came in. They wanted to consider the subject before them from different points of view. In the first place, they had to deal with the generation of current, and in that respect they started exactly from the same source, for they must remember that the ordinary dynamo was nothing more nor less than a simple alternator. They had not only to consider the generation of the current, but also its distribution and its transmission to great distances. Mr. Ferranti had commenced his remarks by referring to some of the disturbances. He dealt with the electrolytic effect upon pipes and metallic coatings. There was another serious disturbance which had caused them many anxious moments, and that was the disturbance of alternating currents upon telephones. He had always said that the telephone was capable of taking care of itself, and the alternating engineer had never to trouble himself about it. Again, another source of difficulty they had met with in their practice were the disturbances to railway signals, for though under normal conditions alternating currents could not affect railway signals, there might be some rushes to earth due to those strange effects that were once called Ferranti effects. There were sudden effects of momentum in alternating circuits which raised the voltage, with the result that there were great surges of current. Such things had and would provide false signals on the block system unless some step was taken to prevent them. That was with regard to disturbances. Another thing that was not a frequent occurrence, but was, nevertheless, very serious in consequences, were the fires that had occurred through the surging effect to which he had alluded. Now, in determining the necessity for the use of either system, they had not only to consider the points he had enumerated, but also the purposes to which the systems were to be applied. They might take electric lighting, motive power, traction, and transmission to a distance. He did not think that there was a single man in that room who would deny that the only practical and possible way of transmitting energy to great distances was by the triphase-current system. No high-pressure continuous plant had yet been constructed which could possibly do what was being done between Niagara and Buffalo, as well as in California, Switzerland, and other places. There could, therefore, be no question that for long-distance transmission, alternating currents were distinctly preferable. With respect to motive power, they were confronted with quite another question. There was no doubt that at the present moment the triphase motor was as good as, if not better than, the continuous-current motor under all circumstances. Mr. Arnold referred to the fact that in his country the continuous current was holding its own, and was displacing the alternating current. He believed the converse also had taken place. The moral was that there could be no serious faults in either, and that one system was as good as the other. An important question was the necessity of standardising the frequency. He could not remember all the causes of these differences in frequency, but he would start with Niagara, where the frequency was 25. There was another large installation where it was 45. In many places in England the frequency of 50 had been introduced. At Deptford they started with 65, and in the City of London he thought it was 97, and probably 100. In the first alternating system in London a start was made with 130. They thus found that the frequency had varied in different parts of the world from 25 to 130, and this showed that there was something wrong somewhere. It might be that certain services required certain frequencies. He believed that the American engineers had established a standard, which was 25 for motive power, 50 for ordinary distribution, and 100 for house distribution where each house had its separate transformer. He thought that the joint meeting would do some good if it would decide that the time had come to determine some standard of frequency, to be applied to different sources. He further wanted to call attention to one line of progress that was being made in England, and that was the distribution of triphase current at high pressure to great distances by means of underground cables. Nearly all the experience in America had been with overhead wires. The largest underground system that he knew of was that established by Mr. Ferranti between Deptford and Trafalgar-square, a distance of nearly eight miles, but underground mains to convey triphase high-pressure currents were destined to undergo a great extension in future years. Engineers should give more attention to the capacity in cables than had been done up to the present time, for when they got long lines conducting 5,000 volts great trouble would be experienced owing to the effects of capacity.

Dr. A. E. KENNELLY, of Philadelphia, remarked that the occasion was a most opportune one for discussing the lowest frequency for alternating systems, as well as for clearing up some of the mists that still hung over the question of alternating and direct current supply. He thought that they would generally agree that not only in America, but also in England and Europe generally, where there was a densely-crowded area to be lighted up with incandescent lamps, nothing better could be done than to employ the direct current at a pressure at which it was to be supplied, and if the area was to be very narrow and contracted there was no need to go above a single lamp—that was to say, 100 volts. As, however, the area extended, the amount of copper put down became so large that a greater pressure was obligatory—say, of 250 volts—and when still greater areas were reached 500 volts would have to be employed. There then came a limit beyond which it would be uncommercial to supply direct current for direct application. Alternating currents must then be resorted to. In many of the large cities of America the heart of the city was supplied by the alternating system on the three-wire plan, and the other portion was supplied by the alternating current of higher pressures. Dealing with electrical traction at a distance, the speaker referred to the anomalous condition of affairs resulting from the employment of the two systems in combination on the American tramways. He said that this method created a great deal of difficulty, and necessitated considerable expense. There was a special set of transformers for reducing the alternating current and another set to reduce the direct current required. It was difficult to understand how such a remarkable confusion arose. He thought it might be claimed to be due to the fact that the electric motor for tramways came into existence gradually as a direct-current system. If, however, in the future all the difficulties were cleared away, it might be expected that this anomalous condition of affairs would be removed, and there would be nothing more than the plain alternating-current system to the utmost limit. The only disadvantage lay in the difficulty of maintaining a stated

Digitized by Google

pressure of distribution. The difficulty which was met with in the distribution by direct current on electrical railroads supplied from distances in this way, was the electrolytic one. There had been much trouble in America on this account. Many pipes had been destroyed, and much damage done, but the difficulty was giving way to careful engineering. It was much less serious at the present time than in the past, because engineers now knew what to do. The damage had occurred not so much to large mains as to surface pipes, and also, of course, to telephone cables, where the covering was continuous, and where there was practically no joint. By careful attention the danger of electrolytic corrosion could be, to a large extent, overcome by not exceeding the pressure of one volt over the danger area, and by carefully bonding the track, etc. The alternating-current motor for tramway purposes had been standardised and perfected, but one disadvantage which had not been pointed out in its employment was the increased danger resulting to those who sustained shocks. A shock of 500 volts with a continuous current was not as a rule very dangerous, and though a great many such accidents happened daily, very little injury appeared to have been caused. But with 500 volts of alternating current the shock might be much more serious, because, as was known, the danger arose from the disorganisation of the heart's action. With the continuous current only one shock was received, from which the victim might speedily recover, but with the alternating current hundreds of shocks were received, and which might be sufficient to disorganise the heart beyond all chance of repairing the mischief. There were, of course, other difficulties with alternating-current transmission in railroads, but it seemed to him that these were of minor importance. There was the difficulty of it affecting compass needles and delicate apparatus of all kinds. The worst that could happen was the banishment of the magnetic observatory to the furthermost recesses of the Continent. This might be a disadvantage in some respects, but a distinct gain to the community.

Prof. AYRTON said that the special point to be attended to in the discussion was, as Mr. Ferranti had said, the advantages of direct and alternating currents with respect to interference. There was no doubt whatever that in many cases there had been a large number of electrolytic and telephone interferences. A serious interference of a special kind had grown up during the past few years with submarine cables, and a case in point was the trouble with the cable at the Cape of Good Hope. Then there had been interferences with the magnetic observatories, to which Dr. Kennelly had referred. There was, of course, no question about the interferences, but there was a decided question as to how these should be dealt with. Should an endeavour be made to destroy the attack, or should the attack be allowed to remain and an endeavour made to improve the defence? Ought an endeavour to be made to carry out each undertaking in such a way that it would not cause interference with anyone else? Or should both sides start by assuming that they were at war? If the magnetic observatories were sure of being attacked, all they could do was to try and defend themselves. The British Board of Trade said that there were not to be more than a difference of potential of seven volts between the points of rails if used as return. If he remembered rightly, the regulations did not say how long the line might be with such a restriction, but whether the lines were very long or very short the seven volts would always apply. It had been conclusively shown, however, that the seven-volt rule was not sufficient. It did not give enough protection in the case of a submarine cable which landed near where a tramway ran. It did not give sufficient protection in the case of electrolysis and in the case of any magnetic observatory which might be located in the neighbourhood of the tramway. In the case of the telephone it was possible to obtain a very good defence, and to make the telephone people more or less independent of the attack, by employing metallic returns, and it was the ease with which the defence could be carried out that led the committee of the House of Lords a few years ago to decline to place restrictions in the way of tramways. The conclusion come to in England was that the telephone system was so shockingly bad through cross-talk that if there were no tramways or distribution on a large scale, it would still be necessary for the telephone companies to resort to metallic returns. This did not, of course, apply to water-pipes and gas-pipes, and where good return circuits were not obtained these were electrolysed. He now came to a very important point which had not been suggested—namely, that the electrolytic disturbances would be very different in character if direct currents were used to what would be if alternate currents were employed. If a general system of alternate currents was adopted, would there be freedom from electrolysis? That was a point which had interested him for some time past. He had been making some observations in Geneva, where the pipes had suffered, and it was not clear whether, in the event of alternating currents being exclusively employed, the pipes would be free from electrolysis. Some time ago he showed an interesting experiment by taking an ordinary sulphuric acid voltameter and sending first a direct current and then an alternating current through it. Exactly the same thing occurred in both cases, the hydrogen coming off twice as fast as the oxygen. It could not, therefore, be assumed that no electrolysis took place because the alternating current was employed. Curiously enough, Mr. Trotter, of the Board of Trade, had sent a specimen showing the same thing, which could be inspected by the members present. The label stated that it was one of a pair of lead pipes buried in the earth and corroded with a current of one ampere. It was not like the covering on the cables sent him from Geneva. In the letter accompanying the specimen Mr. Trotter stated: "I add the words 'alternating current' from Deptford in order to show that it was no fancy laboratory current. The pipes were about 6in. apart, the sides facing each other. It took 100 volts. Three coatings of varnish were painted on the lead, but they failed to protect it." It was clear, therefore, that alternating currents would not give protection with any certainty, and it was equally clear that it was very important to examine under what circumstances alternating currents produced electrolysis and under what circumstances they did not. That was a subject which had attracted a great deal of attention, and he should be glad to hear from the meeting the results of any experiments that would enable them to decide upon what should be done with lead pipes in order to protect these from any action from alternating currents. Then they had to consider how best to arrange the water or gas pipes so as to prevent the attack from injuring these. Contrary to what Dr. Kennelly had said, he thought that a good deal could be done to avoid the attack, and he was happy to say that the London tramway companies had not looked at the matter from the point of view that Dr. Kennelly had suggested. The tramway companies did not say that they were going to lay down lines, and if any harm was done to the observatories the latter could go away. The position taken was to ask the observatories to state the least that should be done to secure immunity from disturbances, and the result was that a committee was appointed by the Board of Trade to carry out experiments with a view of avoiding the disturbances produced by the railways and tramways. When the difference of potential did not exceed seven volts, what was the result? Without giving a long account of the various experiments, he could say that these results—for which thanks were due to Profs. Perry and Hooker—were as follows: that within the neighbourhood of the observatories the tramway companies undertook to cut up their lines into one-mile sections; that each mile should be absolutely isolated electrically from the rest of the tramway system; and that it should be fed at the middle of the section. Current should be brought to the trolley wire at the middle and taken away from the rail at the middle of the mile section; and, further, that no point of any rail should be allowed to exceed one-half of a volt, which should be the maximum of difference of potential. They of the observatories had assured themselves, partly from calculation and partly from experiment, that with such a difference of potential the magnetic instruments would not be disturbed to an amount that could be detected by ordinary observation. He was very happy to say that the tramway companies, although they were American tramways, receiving their apparatus from the United States, were looking at the matter from a more liberal point of view,

Digitized by Google

and were prepared to do what they could to prevent disturbances to the magnetic observatories if these would tell the companies the least that was required. There was still another point with reference to alternating currents and tramways. While he was in the United States, he was told that one of the reasons why the alternating current was not used there was because of the difficulty of getting good contact between the trolley pole and the wire when the latter had snow upon it. It was said that there was more difficulty with the alternating than with the direct current. Since that time, in 1897, there had been certain electric railways on the Continent which were using alternating current with overhead wires, and it would be interesting if anyone could state if any difficulty were experienced in getting contact.

M. CORDA, who addressed the meeting in French, said that the polyphase current had a great advantage over other systems for distribution in large towns. The alternating current possessed a great advantage in its application to motive power. He thought that the ideal motor with simple current had not yet been invented. He would refer particularly to a special case where the advantages and inconveniences of polyphase currents, as compared with continuous currents, were very evident, and that was distribution of power in large works, such as sugar refineries. In these installations the polyphase current was spreading very rapidly on account of the simplicity of the receiver. He had been required very often to make plans and calculations for the employment of the two systems under exactly the same conditions, and the conclusions he had arrived at led him to call their attention to two points. The polyphase current was better as regarded working cost. In the works referred to, high tension could not be adopted, owing to the viscosity of the material dealt with, and could not exceed a tension of 500 volts. There were numerous motors working as many as 500 centrifugal pans. Of course the works did not want to spend too much money upon the mains, and the current was distributed by naked cables placed just far enough out of reach to avoid danger. It was apparent that if the central station was far off the self-induction of the line began to play a big part, and the exciter had to be put on the same machine as the receiver. He concluded by referring to the question of compounding the alternators, which he thought was very important; for when the distribution of continuous current was limited to 200 volts, and when it was necessary to employ large currents, the difficulties he had spoken of presented themselves.

Prof. CROCKER, of Manhattan, said that as the subject had been almost covered, and time was very short, he would confine himself to a few points. The subject of the discussion was with special regard to interference. He himself did not think that this was a very important point. There were two interference effects produced by electric currents, and he thought that these might be classed as the inductive and leakage effects. Under the inductive he should include the magnetic effect. The continuous current was purely magnetic, and this was the cause of its disturbing influence upon magnetic apparatus. For example, it affected a magnetic observatory, but there were not many magnetic observatories in the world, and, as Dr. Kennelly had stated, these might be relegated to a point where they would not be interfered with. It did not seem to him that the progress of electrical art should be influenced very greatly by the disturbances to a few magnetic observatories, and certainly instances of such disturbances would not be very numerous. He was therefore inclined to dismiss the point as one of little importance. The alternating current also had an inductive effect, and that was the inductive current taking place in the field. He regarded this as a very serious thing, because there were more telephones than magnetic observatories. Sir William Preece had said that this inductive effect could be largely avoided by metallic circuits, but there were cases where wires were wanted overhead, and under these conditions the inductive effect could hardly be eliminated, because a transposition of the wires was not a complete preventive. In certain cases, and in smaller towns, rounded circuits were used, and it seemed that the production of currents was more serious than the production of a magnetic field. He would say on that account that the alternating current was more guilty than the direct current—that was to say, its disturbing effect without leakage was greater than that of the direct current. The leakage effect was certainly very serious with the direct current, and produced an electrolytic effect, which was the most serious interference that could be produced on other apparatus. Now, the leakage was something that be controlled to a large extent. The production of a magnetic field was very elusive, and overhead the leakage was very small. If the leakage took place underground at several thousand volts, it would produce a short circuit. He had occasion once to test the entire underground network in New York City, which had been purposely split up into sections to be tested, and found that the leakage was not excessive. It was much less than 1 per cent. He believed that in electrical conductors a considerable or an appreciable leakage was a temporary condition of things that would be overcome. The single-wire trolley system was all leakage, as the current went into the earth, but here again, by the use of return feeders, bonds, etc., that promiscuous flow into the earth had been reduced, and he thought that it could be still further reduced until it became an insignificant quantity. If it could be reduced to one-fifth of a volt, that would be below any dangerous electrolytic limit, so that apparently the interferences were not so very different in the two cases. That was to say, the alternating current had greater inductive effect and the direct current had much more serious electrolytic effect, but this latter could be largely overcome by more perfect construction. With respect to the motor question, Sir William Preece had said that he knew of cases where direct current had been replaced by alternating current. He himself knew of cases where the alternating had been replaced by the direct current, so that there was no conclusive deduction to be drawn from these facts. So far as efficiency was concerned, the two motors were almost identical. He had compared the efficiency of the respective motors, and found that at, say, one-third load the two curves coincided almost exactly. The agreement was remarkable, except at low powers, when the direct-current motor had a higher efficiency. In reply to Sir Wm. Preece, he said that the efficiency was not over 90 per cent., but he could give no accurate figures on the point, as he was only making a general comparison of the two systems. This led him to contend that the direct-current motor was more efficient with light loads. As regarded speed, the two systems were the same. The machines were equally good for constant speeds, but when variable speeds were wanted the direct-current motor had a great advantage. This applied not only to stationary motors, but also to tramway and electrical railway motors, and it was on account of this variability that the direct-current motor had advantages for power purposes over the alternating. He did not think that it would have been fair to the direct current to allow that point to pass unnoticed.

Mr. W. M. MORDEY said that he had discussed the question of earth drop on the return circuit of tramways with some of the American visitors, and there was an impression that the Board of Trade seven volts rule could not be adhered to. He had carried out very severe tests with a 25 line of railway, and found that under the fullest load the drop at any point never exceeded five volts. It would be noticed that in the tramway installations the indicating station might show more than seven volts, but, as a matter of fact, the instrument always recorded considerably more for momentary effects than the real effects. If switched on at six volts, it would show 10 volts. One of the chief differences between English and American practice was that a great deal of attention had been given in England to the question of earth drop. The result had been an exceedingly good one. He hoped that English electricians would learn from their American friends some experiences as to electrolysis. What was wanted to be known was the tension that could be employed. He must pass over a great many points, but he would ask them to bear in mind one cure for all trouble of this sort, whether alternating or direct, and that was the double insulated return, which could be applied in all cases. He did not know whether the future would be for the alternating or direct current, but he could not help thinking

Digitized by Google

that its simplicity would result in the alternating being used. Simplicity of transformer would force them to use the alternating current in traction right down to the rails. He could not say whether this would be done by Mr. Leonard's system, where he had an alternating motor on the car; but whatever system might be employed, the alternating current would be used all the way through. The rotary transformer employed so far was a makeshift system, and must be suppressed. If the capital represented by sub-stations, rotary transformers, and the like were put into conductors, it would be simpler and more economical. If the thing came to grief, the copper and aluminium could be taken up and sold. Some of them would doubtless be going to Switzerland, where they would see some interesting railway works, and he would call their attention to the fact that if a train could be started on the Jungfrau it could be started on the severest gradients anywhere else. Then he desired to say one word on the question of effect upon existing interests, and that was with respect to the scientific laboratories and the observatories. He was glad to hear from Prof. Ayrton that there was a chance of laboratories being allowed to remain in large centres. If they were removed from these centres, it would be a great disadvantage. There was a striking example in the Board of Trade, which possessed a standardised laboratory that was supposed to be the only accurate institution of its kind in England. He did not know whether it was accurate. He only hoped it was. On the plea that electric traction works underground would interfere with the measurement of the earth's magnetism, influence had been exerted to prevent the carrying out of the underground electric railway, which was a considerable convenience to London. That was an action it was difficult to refer to calmly. There was no proportion between the enormous advantages of this undertaking and the measuring of the magnetism of the earth. Such small matters as this could not be allowed to stand in the way of an enterprise which was for the benefit of the population of a vast city.

M. MAILLOUX, of New York, remarked that there was only point which he thought had not been fully discussed. In his country a broader interpretation would have been taken of the question submitted to them, because if other industries were reacted upon, it often involved a question whether they could be continued. One of the important points which had been neglected was the influence of the power factor on electric current. Prof. Crocker had pointed out very clearly the similarity in the results obtained with alternating and single current motors. The influence of the power factor on speed was important, because when the speed varied there was a variation in the magnetic field. It was, however, not so important when the E.M.F. varied in the alternating current. In the United States there were several isolated plants which assumed the dignity of central stations. It was under these conditions that many of the difficulties brought under their notice had occurred. A case in point was an installation for manufacturing coffee, where electric current was furnished by a central station, and it was found that, owing to the enormous current due to starting the motors, the machinery in the coffee mills was sometimes put out of action. One of the great objections to the alternating-current motor was that it took such a large amount of current at starting. This was a serious factor as affecting the working potential of a line. Where the motors were running at an approximate load and speed, the problem was simple, but where the motors were stopping and starting and the line distance was great, and the distribution of the load was such as to load some feeders more than the others, the question merited the serious attention of engineers. It was for that reason that the direct current was employed. He wished in that direction to refer to the very pertinent remarks made by their French colleague with reference to one of the factors which oftentimes affected the selection of systems, and that was the cost of the wire. It was true that for large distribution and for large buildings, as well as for underground, where twisted conductors were obliged to be used, the cost of the wiring was naturally great. In the United States the problem was already solved, since their rules compelled them to use iron conduits with two conductors; but in the case of the larger conductors they were obliged to use iron conduits, but not two conductors returning in the same conduit.

Prof. SILVANUS THOMPSON remarked that no observation whatever had been made upon the likelihood of interference on board ship. This was of vital importance, and yet, extraordinary as it might seem, almost all the ships that were equipped with electric light had the continuous current, and, moreover, the very worst kind of continuous-current dynamo had been put on board, and that was the bipolar. He hoped to see a complete revolution in the electrical equipment of ships. No reference had been made to the somewhat greater danger of fire from the leakage of continuous-current conductors when carried through damp districts. Nor had any reference been made to the fact that while for arc lighting there was some advantage in using continuous current, there was an advantage in employing the alternating current for incandescent lamps, not that there was any higher efficiency, for that had long ago been disposed of, but if continuous current was used for incandescent lamp purposes, and the distribution took place over a large area, it would be necessary to go to the high-voltage lamps; and if anyone had taken the trouble to measure the efficiency of the high-voltage incandescent lamp, it would be seen that this efficiency was low as compared with the low-voltage incandescent lamp. He thought that there would be a revolt when it was known what a low efficiency the incandescent lamps of high voltage possessed. He had heard of 650-volt incandescent lamps, but that was impossible with continuous current. He was very sorrow to hear Dr. Kennelly rake up that old question of the greater danger of alternating current. He thought it originated with the Edison controversy, when an attempt was made to damn the alternating current. He did not think that the alternating current was more dangerous than the high-tension continuous current, and, in fact, the shock of the alternating threw the victim back, and did not cause him to contract on to the wire as the continuous current did. With reference to electrical traction on a large scale, he would like to renew the suggestion of Mr. Mordey to those who had not seen the electrical railways in Switzerland to visit that country, and see how the three-phase system was employed for starting the trains on high gradients under severe conditions. He would ask if it were not a question whether all the motors did not give the same force in starting. The three-phase motor, instead of being worse than the single-current motor, was distinctly better. A little more than a year ago one of the railway companies in London devoted a sum of £30,000 to carrying out experiments for an underground line, and the only thing they had tried and succeeded in doing was simply what had been done in Switzerland 15 years ago—that is to say, drive a train by putting down a third rail at the side. If trains were to run at 100 and even 150 miles an hour driven electrically, there would be no chance of success if dependence was placed upon a thing which had a commutator on it. He ventured to say that for exceedingly rapid transport the only chance of success was to take advantage of the flexibility and adaptability of the alternating current.

Mr. WARD LEONARD said that he would merely say that after having experience with what was possible with the continuous current for rapid starting by acceleration, and after having seen one of the most recent installations of the alternating-current system for traction work in Switzerland, he felt when the car started as if there were one donkey-power in front, and it did not convey the impression of the strong accelerated power required for traction. His ideas might be biassed, but when one came to consider the question of rapid acceleration, perfect control, etc., the possibility of all this was found in the continuous current, but no promise, as yet, of its being done in the alternating apparatus. But when one came to consider the question of electrolysis, great difficulties were met with, and it seemed uncommercial to attempt to work continuous current underground. In transmitting over long distances they were all agreed that the alternating current was preferable. What should be done was to put the continuous-current motor on the vehicle, and find some means of transforming

Digitized by Google

the alternating-current energy into continuous current energy in the vehicle itself, and thus eliminate the difficulties met with in electrolytic troubles, and enabling the transmission of unlimited powers over unlimited distances. This only touched upon one point of the general distribution of power which would arise in the future in railway practice.

Prof. PERRY, in closing the discussion, said that it would be preferable not to take any vote, as the discussion was incomplete, and, after describing the arrangements that had been made for the visits, announced that an international electrical engineering congress would be held at Glasgow in connection with the exhibition next year, when there would be nine electrical sections.

After the discussion, M. HOSPITALIER briefly referred to the more interesting exhibits to be found in Class 23, which related to the production and utilisation of electricity. He called special attention to the compound alternator of Maurice Leblanc, which was a very ingenious machine, and also to the mechanism of the Société Alsacienne de Constructions Electriques, and to the 30,000-volt dynamo of the Société de l'Éclairage Electrique, which, he said, was nearly the limit up to which high potential could be produced. There was also the system of distribution of continuous current shown by the Compagnie de l'Industrie Electrique, of Geneva, which was a very interesting one, and another notable exhibit was that of Siemens and Halske, who carried out some very curious experiments, and showed sparks produced at 12,000 volts. As regarded motors, there was nothing particular in the continuous-current line, as this system was now pretty near perfection, and they were not likely to find any great progress. The alternating-current motor, however, had made a good deal of headway, principally in the question of starting, and there were many interesting starting devices in the Exhibition. A three-phase motor shown by M. Buchot was interesting, because, without putting resistance in the motor, great torque in starting was obtained. In tramways there was much which was interesting, but most of this was to be seen at Vincennes, and they would be able to inspect systems of surface contact that were not used anywhere outside of France. He also called attention to the electric locomotives exhibited by Schneider and other firms.

General WEBBER said that in the short time at his disposal it would be impossible to give any complete idea of what was to be found in Class 27 at that marvellous Exhibition. At the head of the exhibitors in that class were Jules Carpentier, Siemens and Halske, James White, of Glasgow, GANZ, of Budapest, and several other firms who had extremely novel and interesting exhibits. Many of the more noteworthy things calling for the attention of electrical engineers were to be found in Class 15. He wished them to particularly bear in mind that the classification, though it might be in some respects a little inconvenient for visitors, was intended to emphasise the practical spirit of the scientist and the scientific attainments of the engineer, by showing instruments used by the savant and also by the engineer in the workshop, with the result that the exhibits were distributed in different classes instead of all being grouped in one section. He called attention to the application of electricity to cooking, which system was being employed in one of the Exhibition restaurants; and he also referred particularly to the use of electricity on ships-of-war; Siemens and Halske having, among other exhibits, a very complete show of moisture-proof telephones.

Mr. GAVEY, after referring to the harmonic system of telegraphy, said that there was also a special cable recorder of a unique type, consisting of a long vertical wire placed between the poles of a magnet. Under the head of telephones, the great changes which had taken place had been mostly in the direction of improving the central exchange switches. The improvements were being carried out in two directions—first, in increasing the number of subscribers that could be put upon the multiplier; and, secondly, in improving the signalling arrangements in such a way as to considerably reduce the labour of the operator. Amongst the exhibits, he would call their attention to the automatic signalling apparatus of the Western Electric Company, of America, and to the very interesting display of the Société Electrique des Téléphones. The American Wireless Telephone Company showed some ingenious appliances, and another thing they would see in this section was a system of carbonising carbon, by means of which the material could be cut and worked in the same way as graphite. As regarded State exhibits, they were recommended to see those of Great Britain and Belgium, which were of a particularly complete and interesting character.

Mr. HERING said that there was not much novelty in Class 29. The Méry lamp had a high coefficient of temperature through the interposition of an iron wire. Metallic salts were mixed with the carbon, which resulted in a white deposit in the immediate vicinity of the arc, and this increased the reflecting power. Prof. Wedding had found that with this lamp 13 watts per candle-power of hemispherical illumination could be obtained. Wisemann claimed that by using a low voltage in the arc lamp he could get a higher efficiency. Ganz also had an interesting lamp with a curved arc. He called attention to the fine exhibit of chandeliers in the French section, and, in dealing with meters, said that there was a great variety, but nothing particularly new. The principle of the Thomson meter was the one most generally used. The Holden meter was also of interest, and the Aron meters were exhibited in large numbers. He concluded by referring to the exhibits relating to metallurgy in the French Section, and, in speaking of accumulators, made special mention of the Fulmen and Phenix batteries.

Mr. HERING proposed a vote of thanks to the American Commissioners for allowing the conference the use of the American Pavilion, and this was seconded by Prof. PERRY and carried unanimously.

Mr. GILBERT informed the meeting that a Pan-American exhibition would be held in Buffalo in 1901, and he invited the electrical engineers to visit that exhibition, which he said would contain the finest collection of mechanism and appliances relating to the electrical engineering industry that had ever been brought together.

VISITS TO THE EXHIBITION.

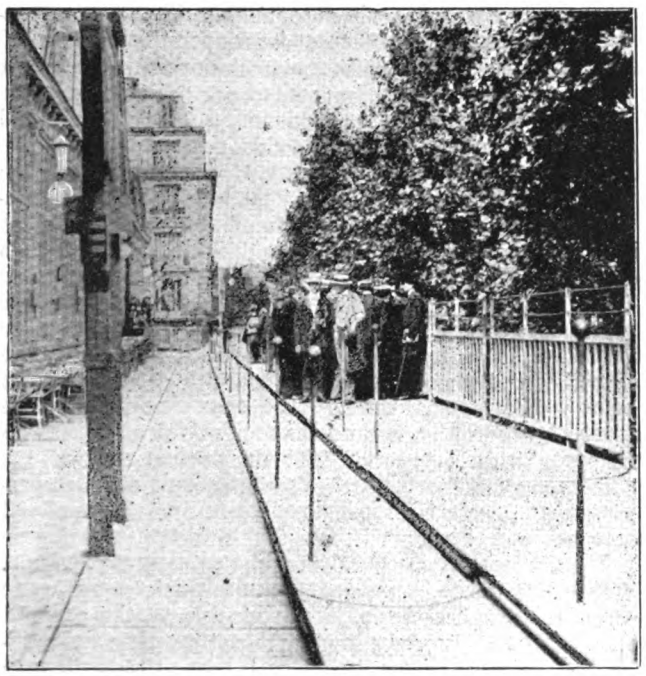
The afternoon was devoted to visits to the Exhibition, when the members were divided into groups and conducted over the Palace of Electricity, where the more interesting exhibits were pointed out to them by M. Hospitalier and other gentlemen. Assembling at the headquarters of the Institute of Electrical Engineers in the American Section, they were first of all taken over the Foreign Machinery Hall, where attention was directed to the installation of C. A. Parsons and Co., of Newcastle-on-Tyne, who have a 500-kw. alternating machine and a 70-kw. continuous-current dynamo operated by the firm's turbines. Galloway's vertical engine, coupled to a dynamo by Siemens Bros. and Co., of London, then came under notice, and leaving this exhibit the members were conducted through the German Section, with its fine display of steam-engines and flywheel generators. After inspecting the stand of Messrs. Siemens and Halske, of Berlin, M. Hospitalier led the group to the Swiss Section, where they saw the machines constructed by the Compagnie de l'Industrie Electrique, which are destined to transport force by continuous current from St. Maurice to Lausanne. They then visited the two switchboards situated behind the Palace of Electricity, the one for continuous current, which supplies the Champ de Mars with light and power, and the other for the alternating current, that serves the Esplanade des Invalides and the banks of the Seine up to the monumental entrance at the Place de la Concorde. Two switches are used for each main, and connect up one of two generators of about the same output, so that either of them can be employed for distributing energy by means of that particular main. A stand that aroused great interest was that of a firm of cablemakers (Pirelli and Co., of Milan) who showed a number of incandescent lamps fed by triphase current at 25,000 volts. Unfortunately, the current was not switched on at the time of the visit, owing to some of the lamps undergoing repair. Going into the French Section, M. Hospitalier said that there was very little of a particularly novel character to be noticed, though one exhibit worthy of attention was the compound exciter shown by Alexandre Grammont, of Pont de Cherui. This system was not perfect, but the maker had gone to work

Digitized by Google

in the right direction, and it might be expected to result in further developments in the compounding of motors. As time was limited, M. Hospitalier could only point out some of the leading features, and the group separated to examine the machines in detail.

The Electric Platform.

On Thursday morning the members visited the moving platform and the electric railway in the Exhibition, and proceeded first of all to the transforming station of the Société Industrielle de l'Electricité procédés Westinghouse, which is situated at the rear of the prominent Schneider exhibit. This installation is supplied with triphase current at 5,000 volts from the Westinghouse alternators in the generating station at Molineaux, four miles distant, and transforms it into direct current at 550 volts for propelling the moving platform and the railway, and for power and lighting purposes generally. There are two separate installations of transformers, which are absolutely identical. The moving platform is started by a 600-kw. dynamo driven by a 850-h.p. induction motor of the three-field type, and running at 290 revolutions at full load. The machine is shunt wound, and runs at 550 volts, the shunt winding being, of course, adopted on account of the very heavy starting current required. The switchboard has some



On the Electric Platform at Paris.

interesting devices, among which may be mentioned the automatic circuit breakers of the laminated brush type, which are thrown out by simply raising a lever with the finger, and another excellent device is the high-tension fusible cut-out, which is extremely simple, and, therefore, effective.

After seeing the platform started, at which moment the meters indicated about 200 volts and 900 amperes, the members left the Westinghouse station and went on to the platform itself. This installation is perhaps too well known now to need any detailed description. It may be said, however, that the platform, which has a length of 2 miles 199 yards, is practically composed of three parts—that is to say, a fixed, a low-speed, and a high-speed platform. The moving parts run at about 4 km. and 8 km. an hour respectively. The low-speed platform has a width of 2ft., and the high speed 3ft. 7in. The platform is built up of sections, each alternate one having rounded ends, and the intermediate ones curved ends. The former run on rails by means of small wheels, and the others are merely supported on metallic guides bolted underneath the rounded sections. The platform is worked by 170 series-wound motors, each developing up to 5 h.p., and a great economy in tractive effort is obtained by an arrangement of springs on the motors and on the small wheels carrying the platform on the rails, which take off some of the load and partly changes the frictional into a rolling movement, so that it runs as if on ball bearings. The consumption of energy for a speed of 5 km. an hour varies from 250 kw. to 300 kw., this latter corresponding to a load of from 20,000 to 30,000 passengers.

SOME REMARKS UPON THE CAUSE AND NATURE OF THE ELECTRIC FORCE.

BY R. C. SHETTLE, M D.

In this paper facts and arguments with regard to the nature of the electric force and its mode of origin, will be briefly set forth in support of the hypothesis that matter was originally formed by the force of cohesion acting upon and condensing a primary stuff; that the residuum of that stuff (which did not undergo condensation into formed matter) constitutes the ether, and is the basis of the electric force. Mathematicians and physicists have based views and theories of the material universe upon their knowledge of matter in its various forms, and of force as the product of motion. Now, mathematical or physical assumptions should be based upon a careful study of all conditions under which matter exists; and inasmuch as mathematical modes of discussing the nature of matter have not included a recognition of the ether as a necessary concomitant, results of such discussions are liable to grave error. This is obvious if matter and ether are realised as coeval entities, the former being the result of condensation in combination with motion in a surviving ethereal medium, such motion generating force or energy.

In support of such view we have but to remember how the existence of the planet Neptune was deduced from the evident action and motion of some *then* unknown material body *upon* already known planets, and through intervening ether. We also fully realise and acknowledge that the spheroidal form of the earth is due to the velocity of its rotatory motion, whilst its material condition had a certain varying density. And we also regard the spherical or spheroidal shape of the magnetic and diamagnetic physical units of the present earth as due to their formation in obedience to the same all-pervading laws of motion. The question will, therefore, arise whether the present results of mathematical and physical enquiries should be accepted as final, or whether the origin of matter by condensation of a primary stuff, of which the existing and now acknowledged ether may be the highly attenuated residuum, is not worth consideration.

In the *Electrical Engineer* of July 27, 1899, I published a paper upon the formation of matter by condensation whilst undergoing rotation, and showed how magnetic and diamagnetic conditions would thus arise. In previous papers I have shown how, by a like process, biological phenomena would be maintained. In the following remarks I seek to explain the nature and origin of electric force; and the effect of calling attention to this mode of explanation may be similar to the effect produced in earlier days by the simple, full, and satisfactory explanation of familiar terrestrial phenomena: referring them to the earth's rotation and revolution around the sun rather than to the old notion (merely) of the sun's revolution around the earth. Before attempting to show how the phenomena of electricity are evolved, it will be well to define the main steps in the formation of matter by condensation of the original stuff, because, hypothetically, it is to the existence of a primary force known as cohesion, and a consequent attachment of ether to molecules thereby, that all natural phenomena can be traced. The general principles of the hypothesis are as follows: it is assumed that space was primarily occupied by a somewhat dense but perfect fluid of uniform density throughout, with absolute cohesive contact of parts or physical elements, and at complete rest. *Note*—Some degree of cohesion would be as essential to the existence of a perfect fluid as the stuff itself, because absolute contact of parts would be maintained by equilibrium of density ensuring equal stress in all directions. The cause of viscosity is thus explained. But cohesion, and *not* gravity, appears to be the proper name for this force of equilibrium of density, more especially from the, *at first*,

Digitized by Google

total absence of particular points or centres of greater density.

The theory herein advanced is based upon the conception of one primary stuff of uniform density, for it would seem that only such a medium could be transformed into a "universe," with its steady, continuous, precise motions, definite arrangement of parts, and regularity of action. Formed from this medium, every *material* atom, even the most minute, would manifest phenomena and distribute energy, whilst interference with the effect of these would imply heterogeneous composition or basic impurity. Nature teems with testimony to the accuracy of such a view, and with effects due solely to admixture of different kinds of matter in bodies subjected to precisely similar influences. But every such combination can be ultimately resolved into substances each with its own specific simplicity and purity, but subserving certain purposes and affecting general behaviour as a form of matter. Now, in the one assumed primary stuff it is evident that no centres or points varying in density could possibly exist as force accumulators or distributors, consequently primary *disturbances*, however strange it may appear, must have originated altogether apart from and external to the stuff itself.

It can readily be seen that disturbance of equilibrium in such original stuff would be the one great primary cause for the subsequent evolution of all natural phenomena. Thus (1) motion originated at any point, or points, in a compressible* (see footnote) fluid, would entail variation of density; (2) variation of density, under cohesion or viscosity, in proportion to its extent would create centres of attraction, by which some of the primary stuff would be radially withdrawn and centrally condensed, originating centres of gravity; (3) the density of each centre of gravity, and the physical properties of matter which resulted therefrom, would be in proportion to the quantity of stuff which had been condensed into any one unit; (4) in proportion to the volume of stuff condensed the residuum would be attenuated, and thus ether of low density resulted or remained; (5) it is obvious that the extent of the stress which each formed unit exercised through the surrounding space, and upon other units, as also upon the ether which pervaded space, must have been in proportion to the mass density of the formed units, and this stress results not only in the condensation of a layer of ether upon the surface of each atom, but in the attraction of surrounding units to form molecules and ultimately masses; all these attractions being effected through the agency of that force which is recognised as cohesion or viscosity, necessarily existent in the purest and most attenuated natural ether.

The cause of "force acting at a distance" is thus capable of being clearly explained: force especially observed (1) when intensified at magnetic poles, or (2) in the field of an electromagnet, when each form of matter under its influence takes a direction according with the form which it assumed when undergoing rotation and being manufactured under the influence of stress originated by its own mass density; and (3) in "universal gravitation," or that force or ethereal stress which regulates the motions of the largest masses of the material universe.

Passing on now to the mode in which upon the foregoing principles the phenomena of static electricity are produced, it will be well to consider somewhat closely the force of cohesion or viscosity of the ether, as exhibited by freshly and smoothly cut surfaces of lead, or polished plates of glass, whose union when placed together is so great as to allow the two pieces to be worked upon as one. Here are two instances illustrative of the mode in which the force is exhibited upon, and extends away from the surface of matter. The very great simplicity of the way in which induction electric machines generate static electricity, according to this hypothesis, will be realised, because the rotation of the glass plate or plates, as the case may be, determines the motion of the ether condensed on their surfaces, and by viscosity of the adjacent and more distant attenuated ether in the same direction. Thus the motion of the glass plates, the density of the glass being much greater than that of the atmospheric matter, draws the ether away from the atmosphere, its great natural reservoir; a process facilitated by strips of paper on the surface of the glass plates, because such strips, in proportion to their density, impart greater density to *definite* portions of the ether than that which pertained to it as generally diffused in the atmosphere. In other words, viscosity is increased with the increased density of the attracted ether. These strips of paper act as channels of supply of ether to the glass plates, just as rivulets feed large rivers, or capillaries the small veins; the plates yield up this ether to the metal points, as bodies of yet greater density, from which it is drawn off by the density of the larger reservoirs or prime conductors of the machine, where it is further condensed and accumulated until its tension overcomes the resistance of the surrounding medium. These machines also present good practical examples of the mode in which light is produced by electric force. Thus the force of cohesion, or ether viscosity, emanating from a molecule of glass on one plate extends in a line through the intermediate ethereal space to a molecule of glass on the other plate, each atmospheric molecule in the intervening space being held upon a definite axis by the lines of stress from both glass surfaces. Now, it is obvious that as soon as the glass plates move in opposite directions (and there is always relative if not absolute motion in the two directions), the lines of stress are twisted upon themselves, and light is the result of molecular attrition under the influence of more or less condensed ether, whilst these lines acting and reacting one upon the other, consequently rotate and cause friction of the molecules existing between them.

In dealing with static electricity, the synthetic formation of water is an illustration of the mode in which condensation is effected by sending charges of static electricity, or, in other words, charges of accumulated ether, through a mixture of the gases oxygen and hydrogen. In the process by which these elements are compressed and combined as water, it is recognised that when the gases are properly associated in a bell-glass jar, and a charge, or, more properly, charges of static electricity, prepared in the usual way, are sent through the mixture, the liquid is formed synthetically, because as soon as the static charges are brought into connection with the gaseous mixture, the condensed or above-mentioned accumulated ether in proportion to increased tension seizes upon the material elements and condenses them by two forces acting in *helical* directions from opposite points or centres of action. (*Note.*—The mode in which the electric force naturally acquires its helical form is attributable to the conjoint motions of the sun and the earth acting upon the intermediate ether in the way to which I have already directed attention, as occurring during the evolution of static electricity by the induction electric machine.) In the electrolytic cell we have the reverse of this. The metal plates, by their relative potentials exercised upon each other, draw the eogen or primary stuff which combines the molecules away from them; and so the water is again resolved into gases.

I therefore pass on to consider voltaic electricity, or that form of force obtained from the voltaic cell, and which Volta named "electromotive force," existing on the contact surfaces of two different substances. And having defined the mode in which this form of force is originated and converted into a state of tension upon Volta's hypothesis, it will be well to comment upon the objections to Volta's theory, as well as upon the suggested "alternative" or chemical source of origin.

Voltaic, or Galvanic, Electricity.—We have the following statements: "If a plate of zinc and a plate of copper dip side by side, without touching, in a vessel of water acidulated with sulphuric or hydrochloric acid, two pieces of copper wire attached one to each plate are found to differ in potential. If the wires are connected with the alternate pairs of quadrants of a quadrant electrometer, a deflection is produced indicating a difference of potentials of about one volt, the potential of the wire from the copper plate being the higher."*

* The compressibility of the ether is shown by its condensation in glass. See Dr. Oliver Lodge's "Modern Views of Electricity," p. 400.

* "Electricity and Magnetism." Joubert, Foster, and Atkinson. Section 96.

Digitized by Google

Volta's Theory of Electrification by Contact.—Volta, in order to explain the observed fact, "supposed that the surface of contact of two metals, or more generally of any two different substances, is the seat of a peculiar force, which he termed electromotive force, the effect of which is to transfer positive electricity across the surface in one direction and negative in the other, until the tendency of the two electricities to reunite balances the force which tends to separate them. He supposed the electromotive force in any given case to depend solely on the nature of the materials in contact, and not upon the size or shape of the bodies, or the extent of the surface of contact, or on their electric state."*

Objections to Volta's Theory.—"The most serious objection to Volta's theory is that it does not afford a satisfactory account of the source of the energy the production of which it implies. . . . The only source from which this energy could be derived, consistently with Volta's hypothesis, is the heat contained in the zinc and copper. It is true that the withdrawal of the quantity of heat required to furnish the quantity of energy in question, rather less than three-thousandths of an erg, would cause an utterly imperceptible fall of temperature in a compound bar of zinc and copper large enough to be used in the experiment, so that the suggested explanation cannot be rejected upon this ground. . . . But when a numerical comparison is made, it is found that the quantity of heat which thus disappears is inadequate to account for the difference of potentials developed in Volta's experiment. It is further found, when other pairs of metals are tried, that not only is the fall of temperature due to the passage of electricity across the separating surface generally insufficient to account for Volta's results, but that there is no recognisable relation between the magnitude of the change of temperature in the one set of experiments and the difference of potentials observed in the other set. *In fact, there appears to be a real difference of potentials between different metals in contact, arising in some way solely from their own properties, which enable them to transform thermal energy into electric energy, but this difference is, in general, much too small to account for the effects now under consideration, and it does not always agree with these even in direction.*"†

The Alternative, or Chemical, Theory.—Passing now to this theory, in which "we no longer look for the source of the required energy in the surface of contact of the two metals, we may enquire whether it is not possible for it to be furnished by chemical action taking place between one or both of the metals and the air or liquid with which they are in contact. It is well known . . . that chemical combination, or decomposition, is associated in a definite way with the transfer of electricity between the bodies taking part in the action, and that the occurrence of a fixed amount of chemical action involves the transfer of a fixed quantity of electricity. . . . The connection above alluded to between chemical action and transfer of electricity *naturally suggests the idea that a definite electric charge is uniformly associated with each atom of a chemical substance.*"‡ *Note.*—Chemical action is thus referred to electricity, but the question to be solved is the cause of the electricity.

Following the text of the discussion on this subject in "Electricity and Magnetism," Section 100, it will be found that the conclusion finally reached is that the electric force is in some manner intimately associated with the molecules, but yet outside them. Thus "a molecule of oxygen gas consists of two atoms *which are in some way held together, and the connecting force has been likened to, if not actually identified with, electrical attraction, a molecule of oxygen being represented by the symbols* $\overset{+}{O}\ \overset{-}{O}$."§

Consequently, the problem as to the nature of the force and the cause of its existence remains quite unsolved by either Volta's theory or by that of chemical action; because, while both recognise the *existence* of a force, neither attempts to define its primary cause, Volta's theory referring it to an *electromotive force* which resides on the contact surfaces of any two different substances, whilst chemical action refers the force to the difference of potentials between the positive and negative layers of matter, *but does not offer any suggestion why difference of potential should produce such effect.*

On the contrary, the hypothesis herein brought forward explains that both these theories are quite correct as to the existence of a force, its seat beween the units, and that one of its functions is to bind these units together in proportion to the potential of each. For when the two units are separated, the ether, which it must be remembered is attached to *each* of them, is strained. The E.M.F. developed depends not merely on the mechanical force applied in separating them, but on *the strength of attachment of the ether to each unit.* The theory also goes further, and traces the force back to the great primary form of physical force—viz., cohesion or viscosity—in which form it was coexistent and equally distributed with the primary stuff itself throughout that which we call space—in fact, it appears to have had its origin in the absolute contact of contiguous parts of the primary stuff, its first function seeming to have been to maintain equilibrium of this stuff, and so adapt it upon a very broad principle to the formation of every kind of matter required in or by the material universe. Thus when equilibrium was disturbed by external stress or power, cohesion became an active force, each centre of stress, in proportion to its intensity, attracting the stuff throughout a given radius by the modification which the force had undergone. It is obvious that the force did not cease to exist at the circumference of the formed material units, because each of these would drag upon the residual stuff only in a lesser degree—*i.e*, in proportion to the attenuation of the stuff and the cohesion and viscosity which still existed, and a certain quantity of this stuff, the quantity varying with the density or the potential of the unit, would be condensed and added upon the surface of each. Attenuation of the residuum would be further effected thereby, whilst the same force acting through this medium would cause the atoms to combine and form molecules and masses, the density of which would be also in proportion to the intensity of the force of cohesion, or the pull which the potential of each unit exercised.

This hypothesis, and the foregoing statement of facts, appear to afford justification for asserting that not only is the ulterior or secondary force of electricity thus completely explained, but that all natural phenomena throughout the three kingdoms of nature may be simply and wholly referred to modifications of the primary force, cohesion, in accordance with the nature and conditions of the matter with which that force is associated.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

EIGHTH ANNUAL MEETING AT KIEL.

[BY OUR OWN CORRESPONDENT.]

(Continued from page 231.)

The following is the conclusion of Prof. Wedding's discourse upon arc lamps of the "Bremer" type, commenced in my last instalment of the Verband proceedings at Kiel:

"I also experimented with an alternating arc lamp of the Bremer type. Table VII. gives the measurements relative to this lamp, which consumed about 6·5 amperes at 39·3 volts terminal potential when unprotected by a globe:

TABLE VII.—Alternating-Current Arc Lamp without Globe. ⁓6·5 amperes × 39·3 volts.

Angle relative to the horizontal plane—Deg.	Intensity of light.
16·8	102
24	219

"From this data the curve in Fig. 7 is obtained. The lamp, however, on account of its rough construction, did not burn uniformly, and for a mean intensity of light, amounting to 512 candles, showed a specific consumption of about 0·5 of a watt, though this is certainly about a half only of the energy hitherto consumed for the same volume of light. Hence an advance upon present practice is also apparent here, and I believe that with a mechanically improved lamp, an efficiency approximating that of the continuous-current lamp already described can be obtained, so as to render the employment of alternating-current lamps possessing a relatively high specific consumption unnecessary.

"In taking the above measurements the special carbons were used only on one side of the lamp, as in the case of the continuous-current lamps. The carbons were placed in pairs, these pairs having an almost vertical position relative to each other so that three current paths might be distinguished. In one the current flowed from the top downwards, in the second from below upwards, in the third taking a horizontal direction between the two pairs of carbons at the arcing point. The latter path is movable as an arc, and is repulsed outwards by the other two paths according to a well-known observation by De la Rive. The arc is therefore deflected downwards in the form of a feathery flame. The greater the intensity of current employed the farther accordingly will the arc be projected.

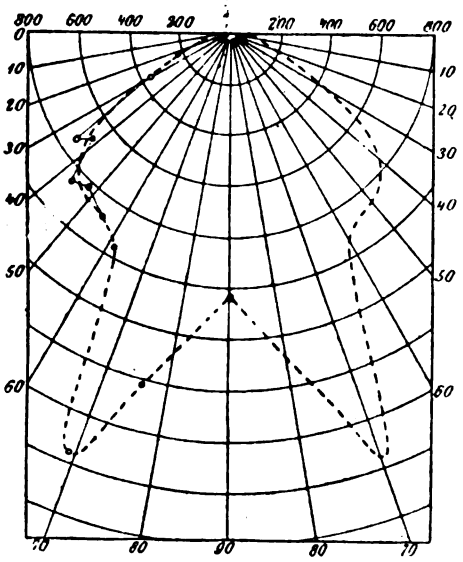

Fig. 7.

In arc lamps designed for low intensities the direct influence of the current is too weak, and in order to supplement this the magnetic field produced by two suitably-placed magnet poles is employed, the magnets being excited by a series coil connected in circuit with the lamp. Should the current become too great, the arc may be drawn inwards by the influence of a differential winding. This may become necessary, for instance, if the influence of the three current paths in a lamp taking a large current is alone too great, and the arc is consequently repulsed too strongly.

"For starting the arc a shunt electromagnet may be employed to bring the carbons into contact in the usual manner. Hence if the carbons constituting one pair or pole are suspended after the manner of a pendulum, the influence exerted by this electromagnet, which forms a shunt to the arc, may also be utilised to regulate the length of the arc should the consumption of carbon be ununiform. When the lamp is burning, the carbon feed is rendered continuous by the weight of the carbons supplemented by an auxiliary weight, and not intermittent. The bulky, costly, and extremely sensitive mechanism characteristic of the lamps now in vogue is entirely absent, and yet, according to the preliminary data at my disposal, the new lamp may be made to burn uniformly and steadily. At the express wish of the inventor, I must refrain from giving a more detailed description of the lamp's construction.

"In the case of the ordinary type of arc lamp the light rays proceeding from the arc constitute only a small percentage of the total light rays, whereas the much larger flame characteristic of the new lamp represents a far greater percentage of the total rays. An examination of the arc through a suitable medium makes this at once discernible. Light rays are not only projected downwards from the glowing points of the carbons, but also radiate into space from all sides of the arc. By the admixture with the carbon the resistance of the arc itself is so reduced that the tension across the lamp terminals, despite the larger arc, need not exceed that necessary for an ordinary arc lamp working with the same intensity of current. How far this statement applies when alternating currents are employed remains, however, to be seen.

"In order to utilise the available light to the maximum possible extent, a conical metal cylinder about 5cm. high is fixed above the ends of the carbons, whereby the heat developed in and between the carbons is converged. In this manner a high temperature is obtained, which results in a more gradual consumption of the carbon than would otherwise be the case. At present, however, the rate of the consumption of carbon in the new lamp is about double the ordinary rate, owing to the admixture already referred to. It should, however, be taken into consideration that the ratio of the cross-section of the carbons pertaining to the old system to that of the new is about as 3 : 1, so that the specific consumption of carbon in the new lamp need not necessarily be greater. The products of combustion, so far as these are not of the gaseous order, are deposited upon the inner surface of the cylinder in the form of a pure white fine powder. When the carbon has been compounded with calcium, the latter is found again in the form of a fine powder on the cylinder and upper cover of the lamp. Supposing that the calcium was decomposed and set free in the form of gas, this latter would inevitably attack the metal in connection with the upper half of the lamp or escape into space. But this is not the case. The calcium compound is minutely subdivided in the arc and its immediate vicinity, and probably present in a gaseous state, whence it deposits itself in a fine white powder.

"This deposit constitutes an excellent reflector, so that upon looking into the cylindrical converger the projection of the same appears as a brilliant and intensely illuminated disc. The great volume of light yielded is, therefore, initially distributed over a large surface. Hence the lamp does not possess the intensely piercing lustre common to the ordinary type, but when provided with a globe appears as a fairly uniformly illuminated disc. The formation of shadows is entirely absent in the new lamp. As the measurements and the curve in Fig. 2 show, a by no means inconsiderable volume of light is yielded up to an angle of 48deg. above the horizontal. For interior and street lighting this fact may be of importance, in so far that the side surfaces within the lamp's radius of action would be illuminated to a considerable height, the impression on the eye being thereby rendered more agreeable owing to the slight contrast between light and shadow.

"Photometric measurements do not always suffice; the æsthetic impression made by the light is sometimes the ruling factor. In virtue of the high percentage of calcium employed, the new light is very rich in red rays in contrast to the blue or violet light yielded by the lamps hitherto in vogue. Through the medium of a spectroscope, the bright, broad bands of yellow green and orange rays may be plainly distinguished. The resultant light does not, therefore, possess the cold, fallow tinge to which we have hitherto been accustomed, but a considerably warmer tinge, by which other colours—for instance, green—are much better defined. In my opinion, however, the colour in comparison with sunlight still leaves something to be desired; it still makes a piercing impression on the eye. This objection may, perhaps, be surmounted by incorporating other metallic salts, as in the case of the gas incandescent light, even at the danger of somewhat increasing the specific consumption. The inventor claims to have the colour of the light fully under control.

"It is a well-known fact that light possessing long wave-lengths will penetrate mist or fog better than light of shorter wave-lengths, in virtue of which a red ray is discernible for a greater distance than a violet ray of equal strength. I have, therefore, examined into the relative

Digitized by Google

penetrative powers of the light yielded respectively by the new and old types of arc lamps. A lamp of each type was tested with approximately the same intensity of current at an angle of 45deg. The test to ascertain the intensity of light yielded was conducted in each case once without, and a second time with, the inclusion of a cloud of steam. This steam cloud was produced by blowing-off a steam-boiler under conditions as equal as possible. There arose between the photometer and the respective lamp a dense cloud of steam about 1m. in thickness. The test could be made only in a very rough manner, since the blowing-off process did not always yield like results. A series of 10 tests gave values for the penetrativity of the light differing by no means inconsiderably. The results, however, showed clearly that the penetrative power of the new light rays through steam exceeded by 40 per cent. to 150 per cent. that of the ordinary arc light. Hence it is safe to assume that the penetrativity of the new light is 100 per cent. greater than that of the old. For signalling, light-house, and other purposes, the light may attain to some importance. But whether it will prove equally adaptable to the conditions of searchlight work remains for the future to determine. At any rate, no solution of the latter question is yet forthcoming."

(To be continued.)

MORE MIRACLES!

[BY OUR VERACIOUS INTERVIEWER]

"The latest startling announcement of the inventor Nikola Tesla is that he has discovered a perfect insulation for electricity. . . . The plan is by a chemical process to freeze a mixture of water and sawdust in a thin metal tube about the wire carrying the electric current. Tesla declares that electricity will in this way be transmitted from Niagara Falls to the Pacific coast, or through the ocean from New York to London, with no perceptible loss of power. He asserts that the invention will greatly cheapen electricity and cause a revolution in industrial affairs."—*Daily Mail*, Aug. 18, 1900.

Fired with the ambition of capturing yet another miracle, I betook myself in haste to the place where they flourish; in a word, to the residence of the discoverer whose motto is, "If it is but difficult, I have done it already; if it is impossible, I mean to do it." To my surprise I found him digging a hole in his back garden.

When he saw me, he courteously climbed out of the hole, which was already several feet deep, and asked me my business. On telling him that I traded in the miraculous, he looked pleased, and directed my attention to the excavation. "That hole," he said, "will shortly become the hub of the universe. From there will flow a stream of energy that will vitalise this old globe of ours. If you'll take——"

"Certainly," I replied; "a cocktail is my drink at this hour of the day."

My words appeared to disconcert the great discoverer for a moment, but he quickly recovered his equanimity, and ushered me into his laboratory—a weird room, lighted by strangely glowing tubes and bulbs. We drank in silence; but I could see, from the workings of the expressive countenance of the inventor, that his mind was active. When he spoke, I recognised that my quest had not been in vain.

"That hole," he continued presently, "must, before it is finished, penetrate below the roots of the hills, even to the fluid interior of the earth. The heat of that vast collection of molten matter, which we call lava, I mean to utilise as a source of energy. I then expect to upset our industries some. Niagara Falls? Pooh! Coalfields? They'll become mere curiosities."

When I promised to give publicity to this marvellous invention, the proud inventor shook me warmly by the hand. He even condescended to enter into details.

"The idea occurred to me three hours ago, and I have been working at it ever since. Prof. D——r, when I was in England in 1893, showed me some vacuum-coated glass vessels which heat was incapable of entering or leaving. You see my drift now? Glass tubes, each surrounded by a vacuum jacket, will proceed from the hole you have seen, and through them streams of molten lava will flow. The vacuum jacket will prevent any loss of heat, and thus energy can be transmitted from here to London in a manner before undreamed of. You run your lava into your boiler, and there's your steam at once. No ash! No smoke! No—er—anything!"

Here I murmured my admiration. When he resumed, I soon saw the magnitude of this invention. "Do you want to discover the North Pole? You merely direct a stream of molten lava toward it, and of itself it builds a causeway, and at the same times creates a warm and agreeable climate. As you know, I suggested some years ago that London should be entirely roofed in with one gigantic dome. The only objection ever raised to this project was that the smoke nuisance would be intensified. Smoke? Why, every grate will glow with molten lava, and the dome will become an accomplished fact. I shall even have small masses of molten lava enclosed in vacuum-jacketed vessels and sold as cigar lights.

"From these instances you may guess the varied purposes to which my invention would be put. I have applied for a patent in the United States; other countries must apply to me."

The cocktails had disappeared, and as no suggestion of replenishing them was given, I rose to bring my visit to a close.

"There seems to me to be one difficulty," I hesitatingly said "Suppose your vacuum-jacketed tubes should break?'

"Well, if you'll mention *that*, you'll mention anything," was the rejoinder. "If the tubes become broken, they must, of course, be mended."

I then left, in possession of my miracle, and lost in admiration of the ingenuity and resourcefulness of this our greatest inventor.

BRITISH ASSOCIATION.

The following is the provisional programme of papers to be read in Section G at the Bradford meeting of the British Association. It will be seen that valuable discussions should ensue. We are pleased to note that the arrangements of subjects on the various days is such that it will repay engineers who are unable to spend a week in Bradford to run down there for certain days. The section will be opened by a presidential address by Sir Alexander Binnie at 11.30 a.m. on Thursday, Sept. 6. At 2 p.m. on Thursday the following papers will be read: "Bradford Waterworks," by Mr. James Watson; and "The Disposal of House Refuse in Bradford," by Mr. John McTaggart.

On Friday, Sept. 7, the papers will be: "Resistance of Road Vehicles to Traction," by Prof. Hele Shaw, F.R.S.; "Recent Tramway Construction, with Special Reference to the Denerbe System," by Mr. W. H. H. Dawson; "The Coal and Iron Ore Fields of Shansi and Honan, and Railway Construction in China," by Mr. J. H. Glass; "The Use of Expanded Metal in Concrete," by Mr. A. T. Walmisley; and "Power Generation—Comparative Cost by the Steam-Engine, Water-Turbine, and Gas-Engine," by Mr. J. B. C. Kershaw.

On Saturday, Sept. 8, Prof. R. Beaumont will read a paper on "The Application of Photography to Textile Designing."

On Monday, Sept. 10, the report of the Small Screw-Gauge Committee will be read by Mr. W. A. Price, and the following papers: "Measurement of the Tractive Force, Resistance, and Acceleration of Trains," by Mr. A. Mallock; "The Liverpool and Manchester Electric Railway," by Sir W. H. Preece, F.R.S.; "The Design and Location of Electric Generating Stations," by Mr. A. H. Gibbings; "A Maximum Demand Meter," by Mr. T. Barker; "An Account of a New Form of Self-Registering Rain-Gauge," by Mr. J. W. Binnie; and "The Automobile for Electric Street Traction," by Mr. J. G. W. Aldridge.

On Tuesday, Sept. 11, the papers will be: "A New Form of Calorimeter for Measuring the Wetness of Steam," by Prof. J. Goodman; "The Internal Architecture of Steel," by Prof. Arnold; "Shop Buildings," by Mr. E E. Clark; and "Steam Raising and Smokeless Combustion," by Mr. H. R. Armitage.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E C Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	5s. 6d.	10s. 6d.	21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered, price 8s. 6d.

THE PARIS CONFERENCE.

When it was first proposed to hold an international conference of electrical engineers in Paris, a programme of the various subjects which ought to be discussed at this conference was drawn up by the French executive. We commented at the time on the utter absurdity of even suggesting that discussion was possible on only one-tenth of the number of subjects put down. In this case time has proved that our contention was correct, as at the conference last week practically only one subject was opened for discussion. This subject was "The Relative Advantages of Alternate and Continuous Current for a General Supply of Electricity, especially with regard to interference with other interests." As will be seen from the report by our special correspondent, electrical engineers from Great Britain and the United States, as well as French engineers, took part in the discussion on this important question, which has been discussed so frequently before. Without wishing to draw comparisons, we would express our opinion that the opening remarks of Mr. Ferranti started the discussion on the correct lines. We are sure that much more value would have been imparted to the discussion had other speakers discussed the matter from the same standpoint. In the struggle for existence in nature, all failures are destroyed without mercy, and in engineering progress the fittest only can survive. What has been done in the past in electric distribution of light and power, is in almost all countries an exceedingly small proportion of what has to be done in the future. Hence a system of supply which may have done exceedingly good work in the early days, may be quite incapable of extension to meet the enormous demands of the future. This was the standpoint taken by Mr. Ferranti, and it is from this point of view that a decision is wanted as to whether the continuous or alternating current system should be laid down in the future. For the transmission of power to a distance, the alternate-current system has proved itself the best; and the interest in the discussion was largely on the question of the distribution and supply of energy. It will be seen that several eminent engineers from the States do not consider the alternate-current motors capable of fulfilling the requirements of electric traction, or of giving the same results in rapid transit as can be obtained by the aid of continuous-current motors. Such engineers take an advanced view of the interference question, holding that interference by leakage currents to other conductors in the ground and to laboratory instruments should be borne by the public without demur, in consequence of the advantages conferred by the rapid system of communications. With this we can hardly agree, and think that the insulated return for electric railways is a necessity in large towns. Mr. Ferranti questions even then if it is possible to prevent electrolytic troubles, and this question can only be answered by practical experience on a large scale. The whole problem is an extensive one to be discussed at a convention, the members of which are practically on holiday, when the tendency is not

Digitized by Google

to give the deep forethought to one's remarks which the importance of the matter at issue demands. If the joint institutions were to state, say, three different cases of power transmission and distribution all on a large scale, with local conditions varying, we think that the vexed problem of continuous *versus* alternating currents could be practically solved by sending out to the experts of different nations the cases in question, and perusing the answers received as to which system each of these experts would recommend in each of the three cases. Even if a handsome fee were sent to each expert with the problems, the replies would be worth the expense, as the profession generally would benefit.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE NATURE OF ELECTRICITY.

SIR,—Kindly permit me to point out that near the end of my article on "Dr. Shettle's View of the Ultimate Nature of Electricity," published in your issue for Aug. 17, a rather unfortunate verbal error occurs. See line 17 of p. 233, column 1: the words "copper to zinc" should read "zinc to copper." The point at issue is that whereas in a Zn-Cu cell with acid, the current runs along the external circuit from Cu to Zn, with contact of two pieces of dry metal, electricity is transferred from *Zn to Cu*.

I believe this was correctly stated in my manuscript. As this slip vitiates the reasoning in this part of the paper, perhaps you would kindly correct in your next issue.—Yours, etc., SPENCER L. FLETCHER.

38, Lammas Park-road, Ealing, W., Aug. 18, 1900.

THE DAVY ENCLOSED ARC LAMP.

SIR,—The secretary of the Jandus Company in his letter published in your issue of the 17th inst. displays a touching solicitude for the Jandus licensees, but it seems to me that his anxiety might well have been limited to his own company. The extraordinary but unsuccessful efforts which Mr. Gillies is making to explain away in the Press the abandonment of the Jandus Company's action against me is a proof—if proof were needed—of the hopelessness of his company's attempt to justify their allegation of infringement. Inasmuch as his letter has been interpreted by some of my customers and friends as a threatening one, and as such is calculated to injure my business, I beg that you will let the facts speak for themselves.

While I can understand that the truth, that the Jandus Company have "wholly discontinued" their action against me, may be damaging to that company, I cannot possibly see where the injustice comes in. In the latter part of last year the Jandus Company commenced an action against me alleging infringement of certain of their letters patent, and claiming an injunction, damages, and delivery of the lamps made in infringement. My defence was that I had not infringed their letters patent. While the matter was before the High Court, the Jandus Company repeatedly applied for extensions of time, and apparently exhausted every possible legal method of postponing the date when the action could be set down for trial, and as they failed to set down the action for trial within the extended time allowed, an order was made dismissing the action, and in addition, on June 22, the Jandus Company served a notice (a copy of which I enclose) "wholly discontinuing the action." Prior to serving the notice of discontinuance, repeated efforts were made by or on behalf of the Jandus Company to induce me to accept a license for a merely nominal consideration, or on a basis of a "union of interests." I absolutely declined to do anything that would involve my accepting, either directly or indirectly, a license from the Jandus Company.

No proceedings in the nature of a test action or otherwise are at present pending against me; what the intentions of the Jandus Company may be in this respect I neither know nor care. The Jandus action against Messrs. Johnson and Phillips is in no sense parallel with their abortive action against me, for I never was, and never shall be, a licensee of the Jandus Company.—Yours, etc.,

London, E.C., Aug. 22, 1900. WILLIAM JAMES DAVY.

PARIS EXHIBITION AWARDS.

We notice the following awards obtained by British exhibitors at the Paris Exhibition:

GROUP 3.—APPLIANCES AND GENERAL PROCESSES RELATING TO LITERATURE, SCIENCE, AND ART.

CLASS XV. (Mathematical and Scientific Instruments).—"Hors Concours": Sir W. Abney, Messrs. C. V. Boys, Christie, Davidson, Dr. J. Mackenzie, J. Milne, Sir W. Roberts-Austen, J. J. Thomson, Thorpe, Hutton. Grand Prizes: Gas Referees of Board of Trade (collective exhibit of mathematical instruments made in the United Kingdom), Cambridge Scientific Instruments Company, Ross, Limited. Gold Medals: James Hicks, Mark Barr (Linotype Company), Watson and Son, Negretti and Zambra. Silver Medals: Legge and Co., Watson and Son (*? vide supra*).

Collaborators.—Gold Medals (unclassified as to country): James B. Macdowel and Hartman, of John A. Brashear; G. Fecker and W. E. Reed, of Warner and Swasey. Silver Medals (unclassified as to country): Smith; Oberlin, of the Ferracute Machine Company; John Wayne, Moser, of Cambridge; the Scientific Instrument Company; Alfred Higgins, of James J. Hicks; Pitman, Hill. Bronze Medals: Harry Janvier and William Ware, of the Ferracute Machine Company; Brice Gustav Watnecker, of Legge and Co.

GROUP 4.—MECHANICAL ENGINEERING.

CLASS XIX. (Steam-Engines). — "Hors Concours": Thwaite Bros. Grand Prizes: Parsons and Co., Willans and Robinson, Galloways. Gold Medals: Marshall, Sons, and Co., Ruston, Proctor, and Co., Ransome, Sims, and Co., Garrett and Sons. Silver Medals: Robey and Co., E. Green and Sons, G. and J. Weir, Patent Exhaust Steam Injector Company. Bronze Medals: James Proctor, Tangye, Limited, Deighton Patent Flue Tube Company.

Collaborators.—Bronze Medal: Lister Croft, of Deighton Patent Flue Tube Company.

CLASS XX. (Various Kinds of Engines).—Grand Prize: Crossley Bros. Gold Medals: Hornsby and Sons, Priestman Bros., Campbell Gas-Engine Company, National Gas-Engine Company, Tangye, Limited. Silver Medals: Ruston, Proctor, and Co., Dudbridge Ironworks, Limited, Robey and Co., Blackstone and Co., J. and F. Howard. Bronze Medals: Cundall and Sons, Dougill and Co., Duke and Ockenden.

Collaborators.—Gold Medals: W. J. Crossley and D. H. Irwin, of Crossley Bros. Silver Medals: George W. Taylor and William Linfoot, of Campbell Gas-Engine Company; W. Turner, E. Pierce, J. Cooke, and A. Hooker, of Crossley Bros.; Herbert Hatton, of Humpidge, Holborow, and Co.; William Wood, sen., William Wood, jun., of the National Gas-Engine Company. Bronze Medals: Albert Mallinson, Samuel Mitchell, Joseph Berry, John Robertshaw, William Yates, Chadwick Smith, Ousey Roberts, and John Jowett, of the Campbell Gas-Engine Company; J. Atkinson, W. Wilson, W. Mitchell, W. Schofield, and J. Carter, of Crossleys; W. Dougill, of Dougill and Co.; Albert White, Samuel Bennett, and Frank Apperly, of Humpidge, Holborow, and Co.

CLASS XXI. (General Machinery).—"Hors Concours": Thwaites Bros., Limited. Grand Prize: Merryweather and Sons. Silver Medals: Mather and Platt, Salter and Co., Wilson and Sons, Mossberg Roller Bearing Company, Stokalls and Sons, Maclaren. Bronze Medals: Dodge Manufacturing Company, Samuelson and Co., Roller Bearings Company.

CLASS XXII. (Machine Tools).—"Hors Concours": Thwaites Bros. Grand Prize: Smith and Coventry,

Digitized by Google

Mather and Platt. Silver Medal: Robey and Co. Bronze Medal: Belshaw and Co.

Collaborators.—Grand Prize: Edward Hopkinson.

GROUP 5.—ELECTRICITY.

CLASS XXIII. (Mechanical Production and Utilisation of Electricity).—Grand Prize: Siemens Bros. and Co. Gold Medals: C. A. Parsons and Co., the Scientific Instrument Company. Silver Medal: William Burton, of James Hicks and Co.

CLASS XXIV. (Electro-Chemistry). — Gold Medals: Electrical Power Storage Company, Chloride Electrical Storage Syndicate, Sherard Cowper-Coles. (?).

Collaborators.—Silver Medal: Herbert Butler, of the Electrical Power Storage Company.

CLASS XXV. (Electric Lighting).—Gold Medals: Benson and Co., Simplex Steel Conduit Company. Silver Medal: R. Beshaw and Co., city of Bath.

Collaborators.—Silver Medal: Lauder and Waterhouse, of the Simplex Steel Conduit Company.

CLASS XXVI. — Grand Prize: General Post Office. Silver Medal: Patent Nut and Bolt Company.

CLASS XXVII. (Telegraphy and Telephony).—Grand Prize: James White. Gold Medal: Crompton and Co. Silver Medal: James Hicks, Stockall, and Sons.

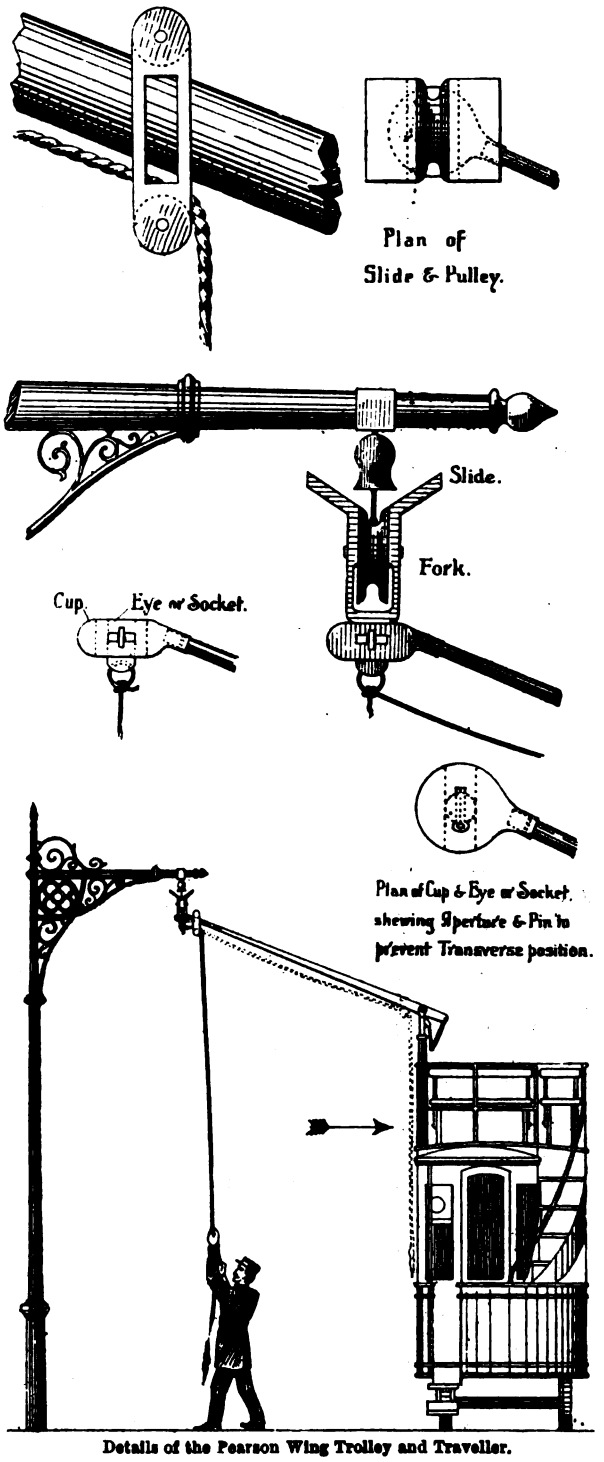
Collaborators.—Gold Medals: Kendall and Gent, Alfred Herbert, Ransome and Co, B. and S. Massey, George Richards and Co, Thomas Robinson and Son. Silver Medals: J. Rhodes and Sons, J. Holroyd and Co., H. W. Ward and Co., Brunton and Trier, Samuelson and Co., Wolseley Sheep-Shearing Machine Company, J. Bertram and Sons. Bronze Medals: United States Metallic Packing Company, Andrew and Co., Wolseley Sheep-Shearing Machine Company (? *vide supra*), Central Cyclone Company, Joseph Parkinson.

Collaborators.—Gold Medals: Oscar Harner, of Alfred Herbert; S. Henry Marl, of Ransome and Co. Bronze Medals: C. W. Jemas, of the Central Cyclone Company; H. Liebert, of J. Holroyd and Co.; John Barker, of Rhodes and Sons; Hughes Cunningham, of Samuelson and Co.; A. J. Thernelee, of H. W. Ward and Co.

THE PEARSON WING TROLLEY AND TRAVELLER.

We illustrate herewith two inventions of Mr. James T. Pearson, of Burnley, which are designed to remove difficulties connected with trolleys for electric tramways. The first of these, the wing trolley, is designed to make it more easy to get the trolley wheel on to the trolley wire, and also to make it more difficult for the wheel in question to leave the wire on the curves. The wing trolley is simply the ordinary trolley with wings (which need not project more than ¼in.), and a slot and pin penetrating the shank of the fork of the pulley, and, being parallel with the latter, allows it to swivel at curves, but prevents it getting across the wire by the ends coming in contact with the sides of the slot. On account of the extra width attained beyond that of the pulley by the "wings" forming a channel, the carman "lets go" the moment the latter is under the "trolley wire," and it engages instantaneously, without wasting time and patience in "dodging."

The other invention of Mr. Pearson's—called the "Traveller"—has for its object the prevention of accidents of the kind which have occurred in consequence of the rope from the trolley head hanging loose. The illustration explains how this is done by means of a traveller, which automatically keeps the rope confined at the bottom of the trolley pole when the rope is not in use. The traveller by means of which this is done only weighs a few ounces, and consists of two skeleton plates, comprising a frame for mounting rollers at the top and bottom. The rod forming the spindle of the rollers has a head at one end and a slot at the other to take a split pin, so that the "traveller" can be readily applied to any arm. When going to change the trolley from one feed wire to another, the carman takes hold of the end of the rope as it hangs down the side of the car and pulls it. The "traveller" then mounts the arm to the end, the trolley is instantaneously let go, and is "contacted" the moment it comes underneath the wire. The carman "lets go" the end of the rope, when the "traveller" descends by gravitating to the pillar of the arm if at the side of the car, or to a stop-piece or clip thereon if in the middle, drawing the rope up out of the way close to the underside of the arm, the end hanging down the side of the car. Simplicity and expedition are embraced in both of these details at a trifling cost, and it would seem that a saving of time would be effected by them.



Details of the Pearson Wing Trolley and Traveller.

MESSRS. DAVEY, PAXMAN, AND COMPANY'S STANDARD IRONWORKS, COLCHESTER.

On Thursday, the 16th inst, the Ipswich Engineering Society paid what proved to be a highly interesting and instructive visit to Messrs. Davey, Paxman, and Co.'s Standard Ironworks, Colchester. The visitors, to the number of about 60, were received at the works by Mr. James Paxman, C.E., J.P. (chairman of the company), who subsequently entertained them to tea. The inspection of

Digitized by Google

the works was conducted according to a prearranged plan, a copy of which was presented to each visitor.

Before describing what was seen, the history of the company may be briefly outlined. The firm of Davey, Paxman, and Co. was established in 1865 by Mr. James Paxman, in conjunction with the brothers Messrs. C. M. and H. M. Davey. Several years later Mr. T. J. Balls joined the firm. Premises were taken in the centre of Colchester, and a substantial business developed, the increase being so rapid, in fact, that land was purchased at the Hythe whereon to erect new works. The site occupies an area of about 15 acres, more than half of which is already covered with buildings. In 1876 Messrs. C. M. and H. M. Davey retired from the firm. In 1885 Mr. Balls also retired, the business devolving entirely upon Mr. James Paxman. Mr. William Paxman, who had been assisting his father for some years, was taken into the firm, and the business remained in the hands of Mr. James Paxman and his son, Mr. William Paxman, until the end of 1897, when it was turned into a private limited company for family reasons. The directors

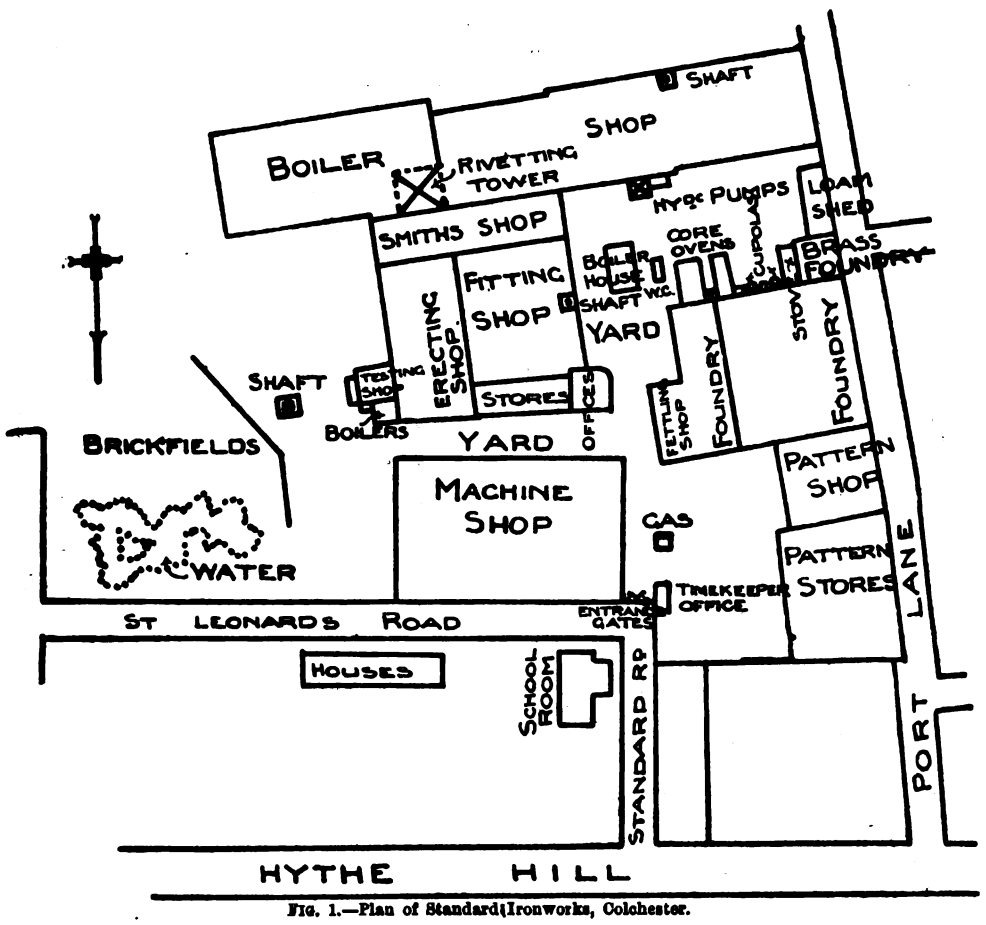


FIG. 1.—Plan of Standard Ironworks, Colchester.

of the company are Mr. James Paxman, C.E., J.P. (chairman), Mr. William Paxman, and Mr. Wilson Marriage, J.P. The secretary is Mr. W. Hedley King It is interesting to note that Mr. Paxman and his son hold the bulk of the shares, the remainder being held by members of the staff. The company devote practically all their attention to the manufacture of steam engines and boilers, air-compressing machinery, mining, and pumping plants, etc., a very large amount of work being done for foreign accounts.

Work was in full swing at the time of the inspection, about 900 men working overtime. The round of the works, which are shown in plan in Fig. 1, was commenced at the pattern stores, a fireproof building covering an area of 12,500 square feet. The patterns here represent 300 complete sets of engine patterns, from 2 h.p. to 1,500 h.p., as well as the other patterns used in the multifarious manufactures on which the firm are engaged. Every pattern is entered in a book of reference, giving the location of the pattern, and whether it is in the stores or in use, so that all patterns can be promptly found with the minimum of trouble. The pattern-making shop, which next claimed attention, consists of three bays, each 90ft. long and 30ft. wide, with a gallery at the further end. The customary labour-saving tools in use in this department are of modern type, and consist of circular saw, band saw, planing machine, lathes, etc., so as to reduce the cost of production of this class of work.

From the pattern shop a move was made to the iron-foundry, the older portion of which covers an area of about 20,000 square feet, divided into three bays, each 45ft. wide. A new extension has been added on the east side of the foundry, which is 140ft. long by 45ft. wide; and in addition, a fettling shop, 70ft. long by 30ft. wide, has been built. The foundry is fully equipped with lifting appliances, cupolas, core stoves, sand mixing and preparing machines, loam mills, etc. The travelling crane in the heavy bay is driven by a square shaft, and capable of lifting 20 tons. There are two core stoves on the south gable of the foundry, each 40ft. long by 20ft. wide, one of which is heated in the customary way with open fires, and the other on an improved down-draught principle. The hot gases are delivered in the top of the stove and the cooler gases are taken away by grated conduits running athwart the floor. This method prevents the cores being sweated when the core stove cools down, and is economical in the use of fuel, the correct laws of convection being duly observed therein. The system of mould drying employed in this department attracted special attention. This consists essentially of an induced draught delivered into covered green sand moulds, whereby dry moulds are obtained without the wasteful and inconvenient use of open fires. The cupolas at the far end of the foundry are capable of melting, as a maximum, 10 to 14 tons of pig iron per hour. At the south-west corner of this department is situated the brass-foundry, proceeding through which the visitors entered the power-house and boiler shop. The older portion of the latter is 400ft. long in two bays of 45ft. each, on to which extensions have been made, continuing the same width of bays for an additional 180ft., thus making the total length of the boiler shop 580ft. One end of the shop is devoted to store purposes and flanging. On the left-hand side, entering from this end, was noticed a "Colchester" compound engine, which furnishes the major portion of the

Digitized by Google

power for this department. There are two flanging furnaces in use and another in course of construction; also one flanging press, capable of taking a plate 8ft. 4in. wide and of exerting a maximum force of 120 tons. The larger press, recently erected, is 11ft. 4in. clear between the columns, and is capable of exerting a maximum force of 300 tons.

Proceeding in an easterly direction from the flanging department, the machine section of the boiler shop was entered. Here numerous fine tools were noticed economically performing a variety of operations in the preparation of the detailed parts of boilers. Amongst the special tools which claimed particular attention was a radial drill, fitted with an attachment for cutting out two holes at the same time in the tube-plates. Also a combined turning mill and boring machine, employed in turning up the flanged ends of boilers and cutting oval holes for man and mud holes. Continuing along the shop, a fine set of vertical rolls was observed, suitable for rolling large boiler shells of heavy scantlings; and beyond this a plate-edge planer, capable of dealing with plates 28ft. long at one setting. Adjacent to this is a multiple boiler shell-drilling machine, capable of drilling four holes at once indiscriminately on the longitudinal and circumferential seams, while opposite is a flue-drilling machine for drilling three holes at the same time in flue joints, arranged so that the pitch of rivets and radial position of the drills can be varied to suit the riveting for the different pressures. Further on, an interesting machine devoted to rolling out the Paxman patent flue joint, of which many thousands have been made, and are giving complete satisfaction, was seen. A considerable variety of pneumatic caulking, drilling, and tube expanding appliances were also noticed. Entering the new extension, the hammers for welding flues were examined. Behind the flue hammers is the hydraulic riveting section, arranged conveniently for dealing with all sizes of boilers. The cranes in this section are designed for loads of 5, 10, and 15 tons respectively. The rest of the new bays are devoted to riveting and finishing the boilers, of which many good examples were in evidence, notably four 9ft. 9in. diameter Paxman "Economic" boilers specially built for electrical power requirements. The cranes in this section are designed for loads of 10 and 25 tons respectively.

With regard to the "Economic" boiler it may be said that this for years has been one of the firm's principal specialities, and has been manufactured in large numbers for electricity supply stations and for many other purposes. It is of the Scotch dry-back type, with some valuable improvements patented and introduced by Mr. James Paxman, notably the arrangement of the two groups of return tubes, which are arranged so as to give the maximum heating surface, and at the same time to admit of complete internal inspection and scaling of the boiler without removal of any tubes or stays. In positions where economy of space is an object of importance—and this condition is practically always a feature of electricity supply stations—the "Economic" boiler has a great advantage. The tubes are cleaned and withdrawn from the front—that is, in the stoking space, so that the boilers can be placed against a dead wall. Further, the boiler has the well-known advantages of a large water capacity—viz., there is a large store of power contained in the form of heated water, of which a part is always available for sudden demands. The large surface at the water-level provides for the perfect disengagement of steam without danger of carrying entrained water with it, thus ensuring dry steam. This large water surface also provides against rapid fluctuations in the water-level, and, in fact, combined with the considerable variation in water-level which is admissible with this type of boiler, allows of great latitude in the supply of feed water and in the working conditions generally. The construction of this boiler provides for ample grate area, a large and very efficient combustion chamber, and ample heating surfaces, so that the very best evaporative efficiency is obtained. Fig. 2 shows the general appearance of the "Economic" boiler.

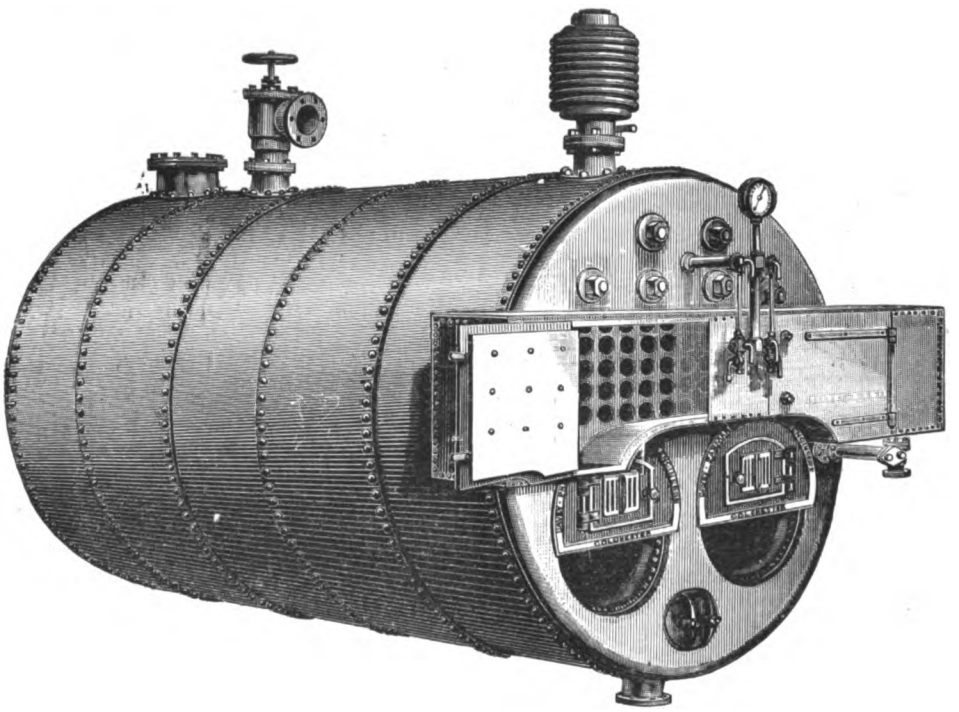

FIG. 2.—Elevation of Davey-Paxman's Economic Boiler.

To those who are not already familiar with the good qualities of this type of boiler, we strongly recommend inspection and enquiry.

THE EVOLUTION OF SWITCH GEARS FOR HIGH-PRESSURE ALTERNATING CURRENTS.

BY W. E. WARRILOW.

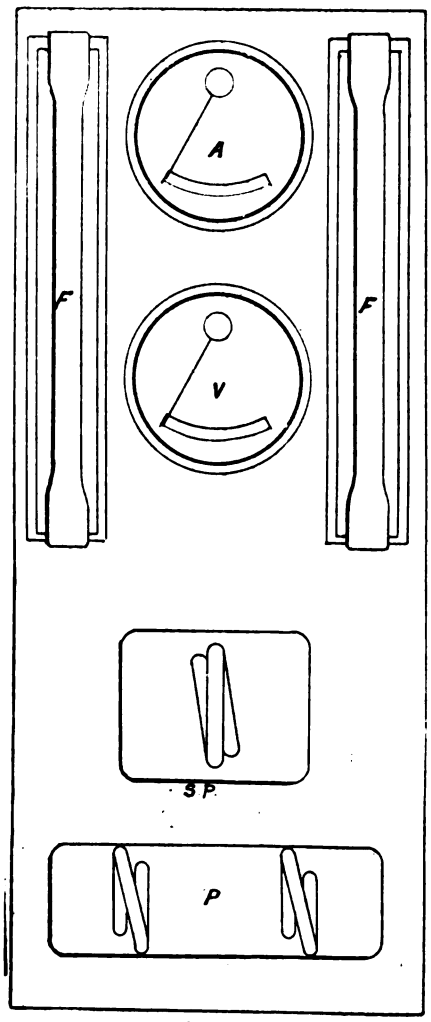
(Continued from page 229.)

CROMPTON.

A form of high-pressure panel constructed by Crompton and Co. is shown by Fig. 17, in which P is the main plug switch; F F, main fuses; A, primary ampere meter; V, machine voltmeter, and S P synchronising plug. The fittings are mounted on a slate slab which is fitted into a teak or mahogany framework. The plug switch is shown in detail by Fig. 18. It is of the double-pole type and arranged lengthwise, so that there is little prospect of the

Digitized by Google

machine being short-circuited by arcs drawing together when the plug is opened under current. The plugs are mounted on an ebonite base set in a wood foundation, and are provided with suitable handles. Contact is made with



IG. 17.—Crompton Panel.

the socket by means of a copper loop bolted to the plug, and the flexibility of this loop ensures a good connection between plug and socket. Should the copper become burned by sparking, it may be easily renewed. The plug is covered with ebonite for a considerable length, to prevent

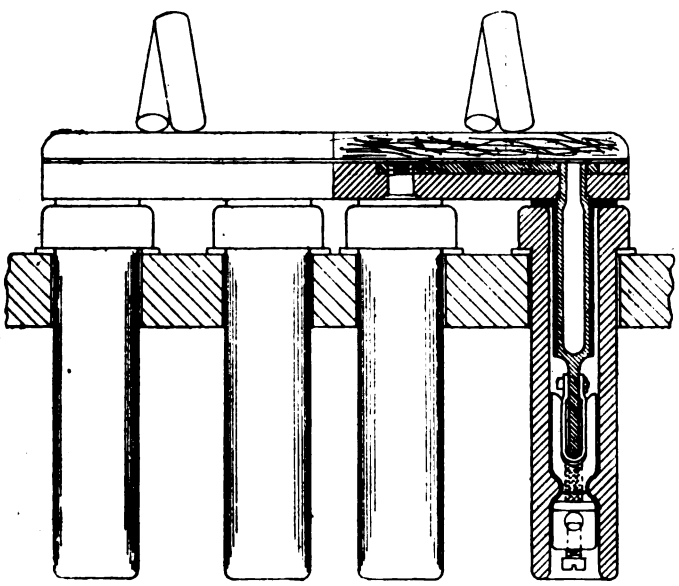


FIG. 18.—Crompton D.P. Plug Switch.

accidental contact when the switch is being withdrawn. The sockets are sunk deeply in stoneware tubes fastened to the slate by screw bolts, the cable connection at the back being well recessed, also, to render the back of the board as safe as possible. The fuse consists of two contacts placed at each end of a stoneware trough and coupled together by spring clips mounted in a porcelain bridge (Fig. 19). The fuse is drawn, or rather threaded, through holes in this bridge, so that the circuit might be opened without an arc forming between the terminals or clips. The shanks on the contacts are carried through holes in the slate having a large clearance, and bolted to porcelain washers, thus ensuring good insulation. The sweating sockets fastened to the shanks are covered with teak protectors, thus guarding the high-tension portions thoroughly. It will be seen that the above switch and fuse are provided with contacts, which may be renewed quite apart from the fittings attached to the board. This is a distinct advantage, and will be evident when a fuse, clip, or plug contact, through overheating or sparking, become damaged and need replacing.

In making up a complete board, the panels shown in Fig. 17 are grouped together in one framing, with dynamos and circuits on either side of a central synchronising panel.

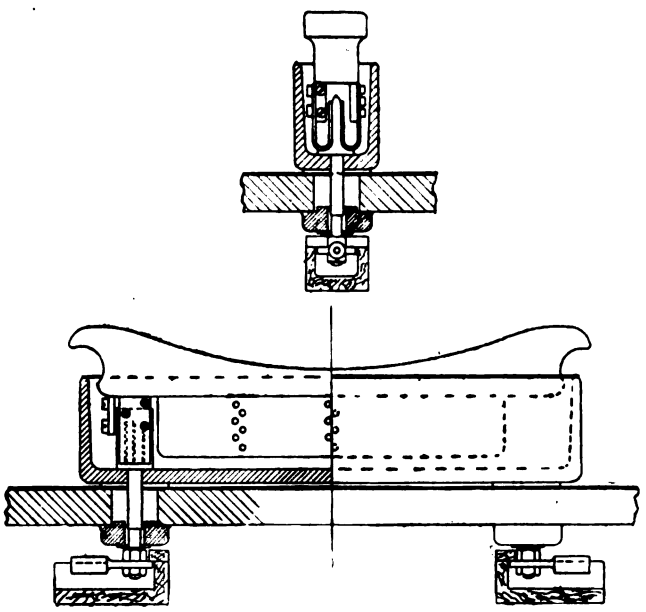

FIG 19.—Crompton H.P. Fuse.

Each alternator is provided with a double-pole plug, by which it could be connected to the synchronising panel, and at this panel it was coupled to the 'bus bars through a pair of light fuses. When the machine had been successfully synchronised, the main plug switch was closed. The exciter panel was placed below each machine panel, and contained a rheostat, ammeter, and fuses. In the centre of the board, beneath the synchronising panel, was arranged the main exciter panel, on which were mounted switches, fuses, voltmeter, and shunt resistances for running exciters in parallel.

Digitized by Google

In connection with this last arrangement, minimum current cut-outs were provided, and in case an exciter failed from any cause it was automatically disconnected. Messrs. Crompton have equipped several stations in this country with alternating-current apparatus.

Lowrie-Hall.

Messrs. Fowler and Sons, of Leeds, equipped many of the early electric lighting stations both with machinery and switch gears, which latter have had a very extended use. They constructed gears of the collected type, making a very neat arrangement of the board. Their main switch of the plug class is shown in Fig. 20, where both plug and sockets are represented.

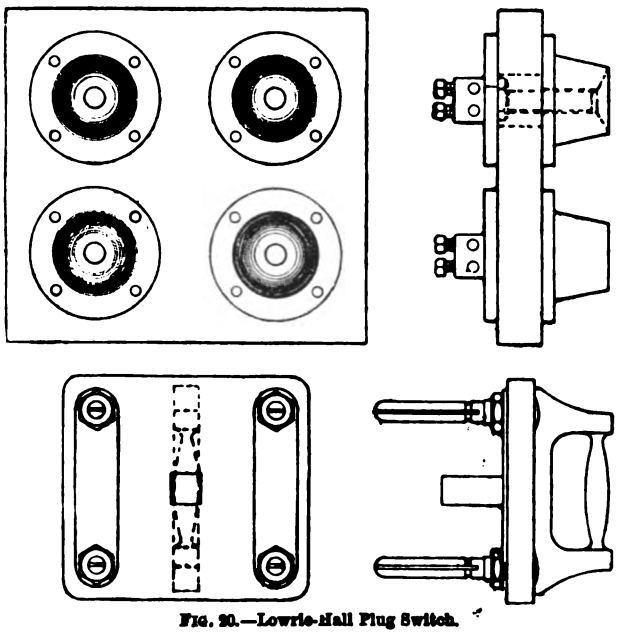

Fig. 20.—Lowrie-Hall Plug Switch.

The sockets are mounted in porcelain insulators, which are fixed to a slate slab of standard dimensions, so that other apparatus, when brought together to form a panel, will occupy the same width and height. Fixed into an ebonite slab are the plugs sawcut down their length to improve the contact, and each pair coupled together by a copper strip. A handle for the insertion of the plug and stop to prevent it going too far complete the switch. The sockets occupy the corners of a rectangle, so that the plug may not be put in the wrong way and short-circuit the two poles.

A main fuse of long break taking place in air is shown in Fig. 21. The contact sockets are fixed to porcelain insulators, very similar to those used in the plug switch, and they are sawn down the one side to allow the fuse plugs to be inserted. These plugs, which carry projections provided with screws for the fuse wires, are mounted in ebonite handles. When in position the fuse wire is recessed in a thick slate, and the arc produced by the blowing of the fuse tends to travel outwards and upwards. With this type the fuse could be renewed by short-circuiting the terminals at the back, but a more recent make has the fuse plugs fitted to an ebonite base with handle, the fuse wire being covered with asbestos. A short-circuiting plug is provided with this latest example to facilitate the renewal of the fuse. Fig. 22 illustrates a slate base fitted with plugs and instruments for synchronising the alternators. Each socket, which is of the concentric type, is connected to the secondary of a transformer whose primary is placed across the terminals of one machine—*i.e.*, each machine has its own synchronising transformer and socket. When two machines are to be paralleled the plugs are placed in the sockets corresponding to the alternator numbers, and as these sockets are connected to half the secondary of each transformer, the insertion of the plugs connects these secondaries in series with one another. The lamp and voltmeter are arranged to be in parallel with the two plugs, so that when co-phasal running of the alternator is attained the lamp burns steadily, and the voltmeter reads 100 volts (unless another pressure be desired).

The regulation of the exciting current is carried out by means of a circular rheostat mounted on a slate of similar width to the slabs on which the instruments above described are fixed. A wood framing is screwed to the back of the slate, with a porcelain base fastened to the end of the frame farthest from the slate. The resistance wires are arranged on this porcelain base, and are coupled to the rheostat stops direct without the intervention of cables. Should there be no room for these frames at the back of the board, they are placed in any convenient position and connected to the stops by cables. Messrs. Fowler also arrange these rheostats to form a table in front of the switchboard, providing the ammeters and field switches on the same arrangement, thus keeping the low-tension circuits apart from the main high-tension framing.

THE RAILWAY AND THE TELEPHONE.*

The substitution of the telephone for the Morse system in the intricate details of the manipulation of traffic has not been encouraged to any considerable degree, but sufficient progress has been made since the last meeting of this association to warrant the belief that the process of evolution has commenced, and that from this time forth the prejudices and uncertainties that have long obtained in opposition to the introduction of the telephone will gradually dispel themselves. I am quite confident that the more you investigate, the more you will be convinced of its availability for all the requirements of railway operations and astonished by its greater elasticity. This latter qualification insures, as a necessary sequence, the most important desideratum—greater safety. Complex situations can be met and determined immediately without the intervention of third parties, verbal negotiations between the various departments regarding the manipulation of traffic can be carried on with the facility and ease of ordinary conversation, though great distances intervene. To obtain these facilities and accomplish these results naturally involves expense, but the expense bears as little proportion to the results as does oil to the operation of the ponderous locomotive.

The telephone develops a new field and performs a new mission. It does not necessarily interfere with the telegraph only in so far as the telegraph falls behind in the race for superiority by failing to develop the new uses to which it might be put. As the situation appeals to me, the telegraph is fast relegating itself to the simple transmission of news, and positive and negative or confirmatory information, too important to be trusted to the slow-going mail service, and not sufficiently important to justify the employment of the telephone. A telephone communication is more or less a personal or private one, and does not involve a third person, and has advantages over any method of transmission. Distances, time, business considerations, and personal discomforts of travel are all eliminated.

It is frequently asserted and generally believed that the telephone is ill adapted as a substitute for Morse in the manipulation of railway traffic. As an old telegrapher, I had strongly held to this opinion, but with the knowledge of what has been done, and a more thorough consideration of the subject, I am a firm believer in the superiority of the telephone. Railway people are too apt to judge the possibilities of the telephone by the crude systems they instal and operate rather than by the standard of the system familiar to the telephone expert. As one of the superintendents frankly stated in his remarks before this association at a previous meeting, referring to certain experiments with regard to simultaneous telegraphy and telephony which he had been making in a desire to furnish satisfactory telephone service to his company, "I don't suppose inductive noises to them (railway employés) was any objection. I know our people would not for a moment tolerate any such noise as that on a telephone circuit, because they were accustomed to the long-distance service, and you know what that is."

Assuming that a railroad is equipped with a standard system, it is pretty safe to say that there is no part of the service but what can be handled more economically, more rapidly, and with greater safety by telephone. A large percentage, if not the entire transmission of service, would be performed by the practical railway operatives, men more familiar and more experienced in the operation of a railway than telegraph operators, many of whom are mere boys, preferably employed because of the small compensation the position justifies. In the use of the telephone every operator becomes, to all intents and purposes, a qualified operative, the switchman equally with the track foreman.

If you instal a system in the manner that obtains on the New York, New Haven, and Hartford road, your regard and opinion for the Morse system will dispel itself. The rapid introduction by railway companies of private branch exchanges is bringing you nearer and nearer to the very scheme of railway operation just alluded to. As these exchanges are established at one point and another the demand becomes more forcible to hitch them up tandem from one end of the line to the other, and the first thing you realise you are operating your system by telephone, and it becomes an indispensable feature. At the same time, you are woven into the great intercommunicating system.

The obstacle to the installation and expansion of this service is primarily its cost, but in considering this cost you should concede there is a factor of expense in the maintenance of wires and stations, established by long experience, below which telephone organisations in the business to stay cannot go. It costs more to ride than to walk, more to telephone than to telegraph, more to telegraph than to write—but weigh the difference! If your general manager had the peculiar and exclusive ability of making every official or employé subject to his control, hear his voice and command, without the interposition of third parties and without the detail of correspondence and red-tape, what would his services command in the railway market? The private branch exchange and its connecting links provide him with this qualification, and it is not reasonable to assert that the employment of these acquired talents moves the wheels of commerce with infinitely greater rapidity, less friction, and with wonderful economy of time? There is no red-tape involved in telephone transmission, greater privacy and secrecy is assured, but, above all, elasticity of operation is the predominating advantage in the railway service.

Ian McLaren, in expressing himself regarding America, exploits a line of reasoning worthy of your sober consideration. "No one, unless he leaves the country, or becomes a crank, can escape from this despotism of activity; he is a part of the regiment and must march with his fellows. No man goes slow if he has the chance of going fast, no man stops to talk if he can talk walking, no man goes in a trolley car if he can get a convenient steam car, and by-and-by no one will go in a steam car if he can be shot through a pneumatic tube. No one writes with his own hand if he can dictate to a stenographer, no one dictates if he can telegraph, no one telegraphs if he can telephone, and by-and-by, when the spirit of American invention has brought wireless telegraphy into thorough condition, a man will simply sit with his mouth at one hole and his ear at another and do business with the ends of the earth in a few seconds, which the same machine will copy and preserve in letter books. It is the American's regret that at present he can do nothing with his feet while he is listening at the telephone."

* Extracts in the *Railway and Engineering Review* from a paper prepared by Henry W. Pope, general manager, Bell Telephone Company, and read before the meeting of the Railway Telegraph Superintendents' Association, Detroit, Mich., June 20, 1900.

LIVERPOOL TRAMWAYS TONTINE.

The following report has been sent to us. It is of considerable interest to all men who join such societies. We have, however, to point out most emphatically that the question of solvency or insolvency does not seem to be really touched by the report of the inspector. The question of solvency of any friendly society is a question for actuaries, not for accountants, and many a society is insolvent whose books show a bank balance of hundreds and even thousands of pounds. Hence we should prefer to see an actuarial examination before whitewashing any friendly society's books:

The inspector appointed by the Registrar of Friendly Societies to examine into the affairs of the Liverpool United Tramway and Omnibus Employés' Friendly Society has presented the following report:

"There were present at the enquiry, which was held in Liverpool, the three applicants—viz., Messrs. John Fleming, John Dawson, and Frederick Coward; the secretary of the society, Mr. George M. Bednal; and one of the trustees, Mr. John O'Neill; and Robert Tilston, clerk to the auditors (Messrs. Harmood, Banner, and Son). The following strangers were, with the permission of both parties, also present—viz., Mr. F. Peacock, trade union secretary, representing the applicants, and himself a late member; Mr. Wright, solicitor, representing

Digitized by Google

the trustees; and Mr. Pierce, assistant town clerk, representing the Corporation. All the witnesses were examined under oath.

"The society was formed under the auspices of the late Liverpool Omnibus and Tramways Company, mainly with the idea of avoiding a threatened strike. The company made it a condition of employment that all their employés should join the society, and it was a rule of the society that none but employés of the said company could become members of the society. The tramways company used to make an annual donation of £200 to the funds of the society, but on the winding-up of the company consequent on the transfer of the properties to the Liverpool Corporation, the donation ceased. The Corporation wished to continue the donation, but had no powers under the Act, and have therefore been endeavouring since then to found another society of their own. They still deduct from the wages of each man his contribution to the society, and this action of theirs was the subject of a test case in the county court lately. The opposition to both society and Corporation, and also the application from which this inspection results, emanates from the secretary of the trades union, and it is evident that the action taken against the society is only an episode of the real fight on other issues between the Corporation and the trades union. As to the allegations:

"Sick Pay being Stopped without Notice.—It appears from the evidence that the payment of sick pay by the society was discontinued for three weeks during September last, but the only witness produced acknowledged receiving the full amount of arrears at the end of that time. No notice was given to members, but the society points out that notice is required to be given.

"That the Society is Practically Insolvent.—As to the alleged insolvency of the society, the society at the present time is quite solvent. At the end of the year they were solvent, and also at March 31 last, as shown in balance-sheets produced to me by the auditors. The only evidence of insolvency is contained in a resolution proposed at a special general meeting of the society at which the directors of the society declared it insolvent. As a matter of fact, being a tontine, it is periodically without a balance in hand after paying the dividend at Christmas.

"All the complainants asserted that the society was insolvent in 1899, but acknowledged having received a dividend at the end of that year, and expected one this year. They could none of them give any evidence of the society's insolvency except in the matter of the arrears of sick pay for three weeks during September last.

"To ascertain as to what purpose the funds of the society have been placed.—From the reports of the auditors, the books, and the evidence at the enquiry, I am convinced that the funds have been disbursed in accordance with the rules—*i.e.*, in paying the expenses of the society in sick pay and death claims, and dividends at the end of the year. The applicants made the assertion that 'contributions and levies are forced from men who are not members of the society.' This is true, but the officers of the society claim that it was done unwittingly on their part. It is a fact that some members have not passed the medical examination required by the rules, and there was at least one acknowledged case where the society returned subscriptions to a man.

"There was also put in evidence a decision of Judge Collier in the County Court of Liverpool ordering the Corporation to repay to the plaintiffs the sum of 5s. and costs, on the ground that they had been collected from him by a society which was not legally in existence. The judge argued that, as the society was limited to employés of a company now dissolved, there could be no society and no members. This case is now the subject of an appeal.

"Regarding the question of proper books being kept, the auditors in their evidence professed themselves quite satisfied. None of the applicants had ever required the books to be produced to him, but the secretary of the trades union, Mr. F. Peacock, asserted that he had once done so, but acknowledged that on being asked to come next day, as the books were at the residence of one of the officials, he had not pressed the demand, and had not asked again. My own opinion, derived from an inspection of the books and the evidence of the auditors' clerk, was that proper books were kept.

"To sum up, after going carefully into the papers and evidence, I do not consider the applicants to be justified in making these complaints and calling for this enquiry. The society's books are in better order than those of most friendly societies. I do not consider it badly managed, and the insolvency, if it can be called so, was of very short duration, and the allegation of membership being forced is a question of law, and is at present *sub judice*. . . . I recognised at the enquiry that the applicants were opposed by a very capable solicitor, and did all in my power to help them, cross-examining them so as to get at all their evidence, and doing what I could to place them in as favourable a position as their opponents.

"(Signed) E. S. GOULDING,
"Incorporated Accountant, Inspector."

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

301. In installations on board ships working with only one insulated wire, and using the ship as the return, which pole of the dynamo should be connected to the ship?—T. P.

302. How would you determine the proper size and lifting power of a travelling crane for an electric generating station?—J. A. S.

ANSWERS.

Question No. 293.—Is it possible to wind the shunt and series winding of a compound dynamo on separate formers in such wise that it shall be possible to remove either the shunt or series field winding without disturbing the other?

Best Answer to No. 293 (*awarded* 10*s.*).—The modern practice in compound-wound machines is to wind the series turns over the shunt. This method has been adopted for two reasons—viz, the usual small size of the shunt wire enables it to be easily brought through the series up to the terminal, while, especially in heavy-current dynamos, if the series be wound at the bottom, there would be great difficulty in bringing the end neatly up to the terminal, and the shunt wire would be greatly disarranged; and secondly, the series turns are very few in number, and in case of any breakdown it is easier to take off the few series turns to get to the shunt, than it would be to unwind the many shunt turns to get to the series if necessary.

From an electrical or magnetic point of view it is indifferent which is the outer. The magnetic effect is inversely proportional to the square of the mean distance the magnetising coil is from the iron core; hence with the shunt next to the iron the main magnetising coil is in its best place, whilst the compensating or series turns, on which depends the regulating of the voltage with varying loads, is in its worst position, being far removed from the iron. Change the position of the two windings and the disadvantages are simply reversed, not removed, the main coil being placed now at a distance from its work.

Consider a straight bar of iron 18in. in length. Suppose a coil of 1,000 turns 6in. long be wound and placed upon it, and a current of five amperes passed through it; the coil will now cause the bar to become an electromagnet of a certain strength, and this strength will not be altered in whatever position the magnetising coil be placed. The result is in nowise changed if the bar be bent into a U or horseshoe shape; the coil might then, equally, be placed on either limb or the yoke. Therefore, in a bipolar dynamo the shunt winding might be put into one coil and placed on one leg and the series winding on the other. There are two or three objections to this course, such as the unsymmetrical appearance of the machine, and also the fact that to accommodate the total number of turns which now must be put in one coil, the magnet leg must be made very much longer than is necessary when the turns are wound in two coils, or else the coil must be wound proportionally deeper. The objection to this latter course is serious, as not only is the cooling surface considerably diminished, but the amount of heat to be dissipated increases with the depth of winding, and also the mean distance of the coil from the iron core is increased. Although a bipolar machine has been taken for illustration, since a multipolar dynamo may be regarded as a series of bipolar ones, the above remarks will apply to any type. It will be seen that this method, while practicable, is not advisable.

Digitized by Google

Another method would be to wind both the series and shunt each on two formers, and fit one of each—it does not matter in which order—on each leg. The only objection to this course is the waste of valuable cooling space occupied by the double former. If, in place of withdrawing one winding entirely from the machine without disturbing the other, it is needful to arrange the parts so that either the series or shunt coils may be unwound without interfering with the other, there is a simple solution of the difficulty; one former for each leg is made, and the shunt is wound along a certain proportion of its length, and the series is made to fill up the residue. The diagrams show a simple method of winding the series when this consists

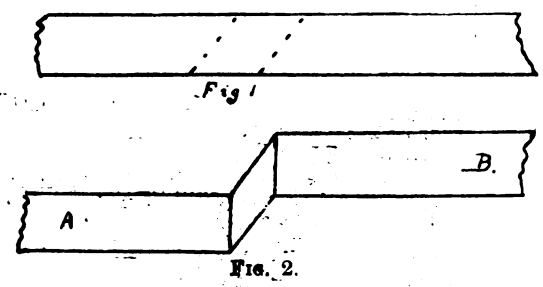

FIG. 2.

of a heavy strip. In order to prevent the unsightly appearance which would be caused by the connecting end of this thick material being taken to the bottom of the coil, halfway along the series strip it is bent along the dotted lines of Fig. 1 into the shape shown in Fig. 2. This is laid on the middle of the winding space, and the end marked A is wound in a right-hand direction, and B in a left-hand direction, which will cause the current to flow in the same direction through the coil; after the completion of the first layer, the two unfinished ends of the strip will be at the ends of the winding length, at the completion of the second they will meet at the centre, and so on. It will be advisable, in order to obtain a good appearance, to arrange the turns per layer in such a way that when the work is completed the ends are at their greatest distance apart. This is a method which has been adopted by more than one of the best dynamo builders. With this arrangement the cooling surface of the shunt is only slightly decreased, and compensation is afforded for this by the more open circulation of air, as the coil is not covered by the series, while if the mean distance of the coil is increased, that of the series is decreased, and they are both put on an equality in this respect.—M.

Answer to No. 293 *(awarded* 5*s.).*—Although in most compound-wound dynamos it is impossible to take, say, the shunt coil off the magnets without disturbing the series coil, it is possible to so wind them on separate formers that either coil may be removed without disturbing the arrangement of the other coil on its former. The compound winding may be arranged either as in Figs. 1 or 2, where A A = shunt coil, B B = series coil, C = core of dynamo. A A may be arranged inside B B in the first figure if required. For the first arrangement I have seen the following device on a small dynamo. A frame was made of sheet brass sweated together of the shape shown in the figure, to receive the shunt coil. When the coil was

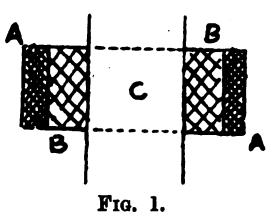

FIG. 1.

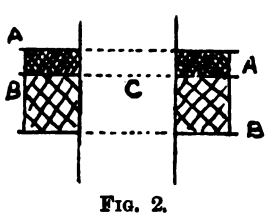

FIG. 2.

wound on the frame, additional L-shaped pieces were sweated to the outside corners, as shown at one corner by dotted lines. A similar frame without the outside corner pieces, of a size to slide over this shunt frame, was made for the series winding. The outside corner pieces of the shunt coil frame acted as guides for the series coil frame. Before the windings were placed on the frames, the latter were taped with Blackley tape, and the end flanges covered inside with pressspahn. The shunt coil was in this case placed inside the series, as the smaller size wire could be wound flatter than the large. It is, of course, necessary to unship both frames if the shunt winding is to be rewound.

There is a similar objection to arrangement Fig. 3—one coil must be shifted to get the other off. There is, however, the advantage that the mean perimeter of both the coils is the same, and so the electric circuit is reduced in length as much as possible in both coils. The arrangement simply consists of two coils ranged one above the other, mounted on ordinary formers. The cheeks of these are often of wood; in this case the top cheek is used to mount the gunmetal terminal blocks.

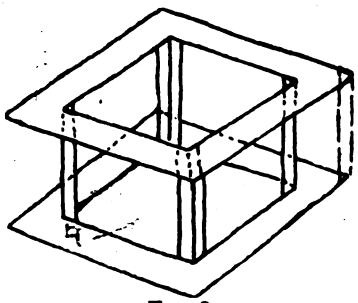

FIG. 3.

The Electric Construction Company have a very neat arrangement of coils in their continuous-current transformers, by means of which either series or shunt coil may be moved without touching the other coil. It consists of having two entirely separate magnets—one being series-wound, the other shunt-wound—ranged side by side along the armature's axis, and designed in due proportion to the series and shunt magnetic fluxes required. Any shifting of the centre of the magnetic field along the axial length due to relative variation of series and shunt currents is so slight as to be negligible.—J. A. S.

Answer to No. 293 *(awarded* 5*s.).*—Winding the shunt and series fields on formers, as suggested in the question, is by no means difficult. It is uncommon in practice, as any slight advantage that might be derived from so doing is more than counterbalanced by the increased expense involved. The writer has come across only one case in point—that of an experimental machine arranged for running under conditions of induction and compounding which could be varied at will, principally for demonstrating purposes. Fig. 1 shows the type of former used. The body of the bobbin was made by bending up a strip of galvanised sheet iron of 16 gauge into the form of a rectangle and riveting the ends together. The seam is arranged so that it falls in the centre of one of the sides, as shown at J. The flanges were also cut from the same sheet, angled and riveted to the body, as shown. The bobbin thus formed was then insulated and wound in the usual way. Fig. 2 shows windings in posi-

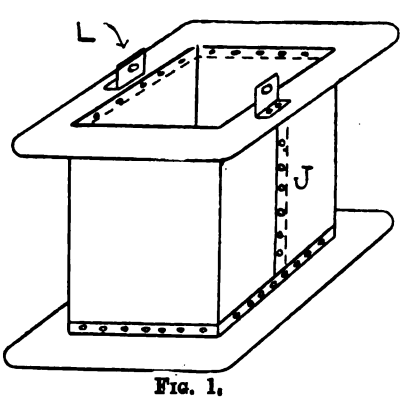

FIG. 1.

tion. The shunt bobbin, S, has been slipped over the magnet limb, and rests on two brass brackets, B. With this bobbin in position, a similar bobbin, on which the series winding has been placed, is slipped over the shunt bobbin and rests on the same brackets. The ends of the windings are brought out on to two terminal boards, T and T_1, one on the magnet limb and the other on the yoke piece. The bobbins are further secured to the limb by means of set screws and the lugs, L (Fig. 1). The machine in question was provided with several sets of

Digitized by Google

interchangeable field coils. To make use of these it was simply necessary to disconnect at the terminal boards, remove the yoke, and lift out whichever coil was to be changed. The machine was also provided with making-up

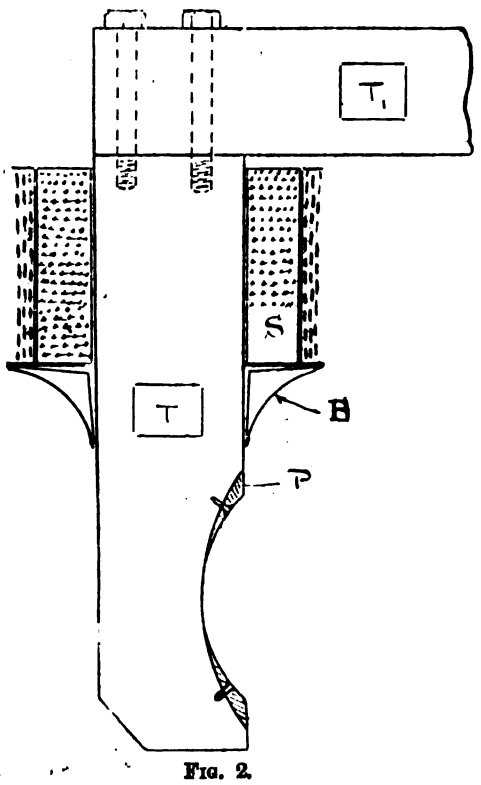

Fig. 2.

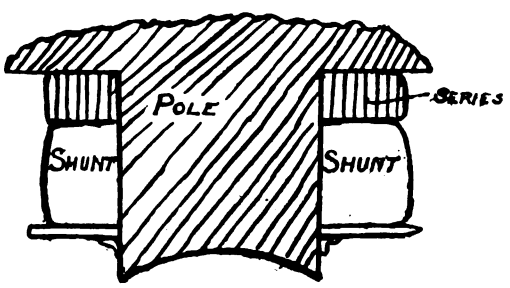
pieces, P (Fig. 2), for use with armatures of different diameters, which also formed part of the outfit, the yoke being so arranged that the distance between the magnet limbs could be varied to suit requirements.—P. S. T.

Answer to No. 293 (*awarded* 5*s.*).—A method of winding series and shunt so that each can be moved independently is shown in the figure. This method is adopted by Mavor and Coulson in their multipolar machines. The coils are not wound on formers, but are built up with tapes. When the coils are wound, they are wrapped over with tape and then varnished. This method is cheaper than using formers, and a brass plate holds the coils in position on the poles. The series winding consists of several layers of tape wound broadways, each layer being insulated. When wound, the series is put on first, then the shunt winding. This looks very neat on the machine. Of course,



it is possible to wind the series on a former and the shunt by means of tapes, as above, and then slip the series over the shunt. In either of the above cases the coils would have to be moved in case of accident to the series or shunt, but from the question it appears to indicate that an easy way of removing either shunt or series is required. A case occurs to mind where the series of a machine, wound in the ordinary way, shorted with the frame, and both shunt and series had to be rewound, but if the above had been adopted, this would have cost far less to repair.—F. M. Moody.

Question No. 294.—Is there any electrical device that will automatically keep the pressure constant with varying loads on battery regulating cells? If so, describe and illustrate same.

Best Answer to No. 294 (*awarded* 10*s.*).—A device for automatically keeping the pressure of a storage battery constant is shown in Fig. 1. The solenoid, A, has a coil of very high resistance, which is connected across the mains. The core, B, is drawn down into the solenoid against the resistance of spring, C. Connected to the solenoid, B, is an arm, D, which moves two wheels, K K1, which are keyed on to a spindle, E. These wheels are free to move in a horizontal position, but when revolving move the spindle, E, which by means of the thread and nut, F, move the contact, G, over the various contact blocks. Revolving power is transmitted to the wheels by means of a friction wheel, H, which is worked by a small motor.

Fig. 1.

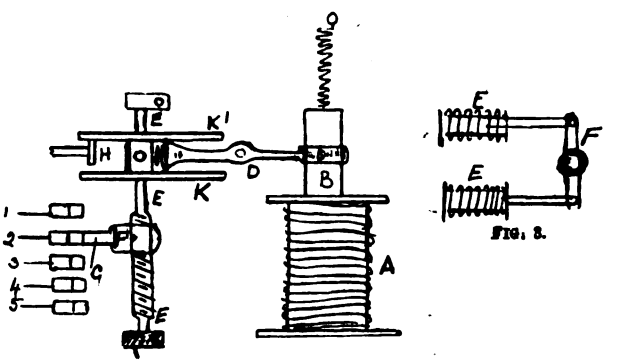


Fig. 3.

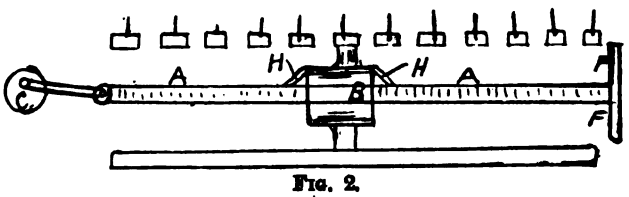

Fig. 2.

The principle upon which this apparatus works is as follows: The resistance of the coil, A, being constant, the magnetic pull on the core, B, depends upon the variations of the pressure. The solenoid, A, upon any variation attracts or allows the core to slip; this in turn moves the friction wheels against revolving pulley, H. By this means the contact block, F, is moved over the contacts, cutting out or putting in cells to keep the pressure constant. The apparatus in use at the County of London Electric Lighting Company's City-road station for the same purpose is of an interesting type, and requires a special switchboard. This board has two rows of charge and discharge blocks gripped on both sides by contact brushes, which grip long connecting bars. The brushes are carried on massive steel bars, and are free to slide along, thus varying the number of cells connected. The charge is set by hand, but the discharge is worked automatically in the following manner: Referring to diagram Fig. 2, the steel bar, A A, on which the discharge brush carrier, B, is fixed, is caused to oscillate to and fro by means of a crank, C, driven by a small motor. If the pressure should rise or fall, a delicately adjusted relay, consisting of a solenoid in series with an adjustable resistance connected across the mains, actuates a mercury switch, which causes a large current to flow through one or other of two solenoids, E E, causing a partial rotation of the bar, A A, by means of the arm, F. The bar, A, has two sets of notches, one on each side, and this partial rotation brings one or the other sets of notches into gear with the pawl, H, on the brush carrier, and the contact brush is carried rapidly forward or backward, until the normal pressure for which the relay is set is restored.—F. M. Moody.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ilford.—The Urban District Council invite offers for free wiring. Tenders by 29th inst.

Lincoln.—The Town Council invite tenders for wattmeters and demand meters. Tenders by Sept. 14.

Hamburg.—Two 30-ton electric cranes are required. Enquiries may be made at the Town Hall. Tenders by Sept. 10.

Preston.—Tenders are invited for the electric lighting of the Preston and County of Lancaster Royal Infirmary. Tenders by Sept. 1.

Digitized by Google

Hampstead.—The Vestry invite tenders for various plant for their central station, Lithos-road, Finchley-road. Tenders by Sept. 27.

Worksop.—The Urban District Council invite tenders for the erection of electricity supply works in Canal-road. Tenders by 27th inst.

Plumstead.—The Vestry invite tenders for the supply and erection of various plant and machinery for electricity works. Tenders by Sept. 19.

Worthing.—The Corporation invite tenders for the construction of a new electric generating station and alterations of buildings at the Corporation yard.

Stockport.—The Tramways Committee invite tenders for 20 double-deck tramcars, complete with electric equipment for overhead traction. Tenders by Aug. 31.

Newcastle-upon-Tyne.—The New Tramways Committee invite tenders for conduits and holes for poles. Tenders by 31st inst. Details in our advertisement columns.

Oldham.—The Electric Light Committee invite tenders for the supply, delivery, and erection of boilers. Tenders by Sept. 11. Full details in our advertisement columns.

Nelson.—The Corporation invite tenders for the supply of a 200-kw. steam dynamo for their electricity works. Tenders by Sept. 8. Details in our advertisement columns.

Southampton.—The Harbour Board invite tenders from crane builders for one 30cwt. portable electric wharf crane. Tenders by Sept. 10. Details in our advertisement columns.

Leeds.—The Tramways Committee invite tenders for the erection of a new boiler-house (all trades except ironfounder) at the generating station, Crown Point. Tenders by Sept. 3.

Middlesbrough.—The Electric Lighting Committee invite tenders for the wiring of the municipal electricity works. Tenders by Aug. 31. Full details in our advertisement columns.

Shipley (Yorks).—The Council invite tenders for steam and exhaust pipes, storage battery, switchboard and connections, and cables. Tenders by 27th inst. Details in our advertisement columns.

Cardiff.—The Corporation invite tenders for the supply and delivery and fixing of sundry pipes, feed-water heaters, etc., at the Corporation electricity works, Eldon-road, Cardiff. Tenders by Aug. 31.

Hammersmith.—The Vestry invite tenders for two single-phase alternate-current motors, coupled to two centrifugal pumps, with accessories. Tenders by Sept. 12. Full details in our advertisement columns.

Horton (Surrey).—The Asylums Committee of the London County Council invite tenders for the installation of boilers, engines, dynamos, etc., at the Horton Estate, Epsom, Surrey. Tenders by Sept. 22.

Greenock.—The Police Board invite tenders for traction plant as follows: water-tube boilers, two steam dynamos (high-speed enclosed engines), boosters, switchboard, steam and exhaust pipes, etc. Tenders by Sept. 10.

Hull.—The Electric Lighting Committee invite tenders for steam and water pipes, feed pump, water softener, etc., at their Sculcoates-lane generating station. Tenders by Sept. 27. Full details in our advertisement columns.

Southampton.—The Guardians invite tenders for the erection and completion of electrical plant and installation for the lighting of the new workhouse infirmary, Shirley Warren. Tenders by Sept. 11. Details in our advertisement columns.

Aberdeen.—The Electric Lighting Committee invite tenders for a twelvemonth's supply of paper or fibre insulated lead-covered feeder, distributing and service cables, electricity meters, and house main fuse boxes. Tenders by 28th inst. Details in our advertisement columns.

Hackney.—The Electric Lighting Committee invite tenders for condensing plant, cooling apparatus, pipework and valves, feed pumps, switchboard and boosters, public arc lamps, meters, travelling crane, and workshop equipment. Tenders by Sept. 12 Full particulars in our advertisement columns.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of the following plant: lighting switchboard, traction switchboard, and balancing transformers at their new electricity works, Strawberry-road, Pendleton. Tenders by Sept. 3. Details in our advertisement columns.

Whitby.—The Council invite tenders for the following plant: two water tube boilers, pumps, condensers, pipes, etc., two steam dynamos, balancer, and boosters, switchboard and connections, battery, travelling crane, and cables, arc lamps, etc. Tenders by Sept. 3. Details in our advertisement columns.

Portsmouth.—The Corporation invite tenders for the supply, delivery, and erection of the whole of the plant and apparatus necessary to completely equip for electric traction their proposed power station at Vivash-road, Fratton-grove, Portsmouth. Tenders by Sept. 4. Details in our advertisement columns.

St. Petersburg.—The Posts and Telegraphs Department invite tenders for the working of the telephone systems in St. Petersburg, Moscow, Warsaw, Odessa, and Riga for 18 years from Nov. 1, 1901. Tenders by Aug. 28. All necessary particulars may be examined on personal application at the Imperial Russian Financial Agency, 107, Cromwell-road, London, S.W., on Mondays, Wednesdays, and Fridays, from 2 to 4 p.m.

Worthing.—The Corporation invite tenders for the supply and erection of the following plant: (1) three 96-kw. steam dynamos (vertical enclosed high-speed engines); (2) two boilers of the dry-back marine type, with fittings, etc.; (3) steam and exhaust, drain and other pipes, in engine and boiler house, pumps, condensing plant, etc.; (4) cast-iron manhole covers; (5) cast-iron arc lamp posts; (6) stoneware casings; (7) cable work; (8) arc lamps; (9) storage batteries; (11) balancing transformers and motor-generators; (12) economiser; (13) five-ton overhead engine-room travelling crane. Tenders by Sept. 3.

Fenton (Staffs).—Tenders are invited for works in connection with the construction of a single line of railway (2ft. 6in. gauge) from Waterhouses to Hulme End, Staffordshire (about eight miles two furlongs), and incidental works connected therewith, for the Leek and Manifold Valley Light Railway Company. Plans, specifications, bills of quantities, and forms of tender may be inspected at the offices of the company's engineer, Mr. Joseph Forsyth, Heron's Cross, Fenton, Staffs, on and after Aug. 4, and copies of same may be obtained from him. Sealed tenders must be sent to Mr. Edward Challinor, secretary, Leek, by Sept. 1.

RESULTS OF TENDERS.

Portsmouth.—An order for a 500-kw. alternator has been placed with Messrs. Parsons and Co. for the sum of £5,300.

Lowestoft.—The Electricity Committee have accepted the following tenders: Messrs. Hands, Limited, London, motors; Messrs. Geipel and Lange, Westminster, cut-outs.

Cardiff.—The Corporation have accepted the tender of the British Electric Transformer Manufacturing Company, Limited, Globe Works, Harrow-road, London, W., at £1,690, for the manufacture and delivery of 10 30-kw. transformers.

Dublin.—The Electricity Committee have recommended the acceptance of the following tenders: General Electric Company, Limited, London, compound engines, generators, etc., £33,061; Messrs. Holdsmith and Sons, Bradford, Lancashire boilers, £6 653; Messrs. Babcock and Wilcox, Limited, London, water-tube boilers, £5,278; Messrs. Holdsmith and Sons, fuel economisers, £1,060.

Bradford.—The Corporation have accepted the following tenders for the work required in extension of the electricity works, Valley-road: Humphreys and Moulson, 441, Little Horton-lane, Bradford, masons, excavators, and bricklayers; Wilkinson and Dawson, Bowland-street, Bradford, carpenters and joiners; B. Rhodes and Co., Limited, The Old Foundry, Bradford, smiths and iron-founders; Hill and Nelson, Edmund street, Bradford, slaters; Bradley, Kriscbke, and Co., Infirmary-street, Bradford, concretors and plasterers; S. Rushworth, Briggate, Shipley, near Bradford, plumber; Servent and Edmondson, Otley-road, Bradford, painters.

Barnes.—The Urban District Council have received the following tenders:

Condensing plant, pumps, oil filters and separators, feed, steam, and exhaust pipes, etc.

Cole, Marchent, and Morley, Bradford	£2,860
J. Simpson and Co., Pimlico	2,800
Aiton and Co., London	2,596
Alley and Maclellan, Glasgow	2,480
Babcock and Wilcox, London	2,239

Section F.—Overhead travelling crane.

J. Whitley and Co., Leeds	420
J. Carrick and Son, Edinburgh	265
Chatteris Engineering Works Company, Chatteris	264

Cardiff.—The Town Council have received the following tenders:

1,000 tons of rails and 40 tons of fishplates.

BUSINESS NOTES.

TRACTION.

Birkdale.—The introduction of electric traction into Birkdale was virtually decided upon by the Council at the meeting on Tuesday night.

Portmadoc.—A special meeting of the Urban District Council will be held to meet representatives of the promoters of the proposed electric railway from Portmadoc to Beddgelert.

Royton.—The District Council are asking the Town Council of Oldham whether they are prepared to meet the District Council with regard to continuing their tramways to Royton.

Bradford.—The new branch of the electric tramways provided by the Corporation for the Lister Hills and Lidget Green district was practically completed last week, and a trial trip was run on Monday.

Croydon Tramways Co.—A meeting of the stockholders is to be held after the next ordinary general meeting for the purpose of passing the necessary resolutions for the winding-up of the Company.

Southport.—A scheme is on foot for connecting Liverpool Central (Low Level) with Huskisson (Cheshire Lines) by means of electric tube trains, much after the fashion of the now famous Central London Railway.

Burton-on-Trent.—A scheme is on foot for connecting Woodville with Burton-on-Trent *vid* Swadlincote and Newhall. The line is to be of standard gauge so as to allow of using the railway trucks at night time. The overhead system of electric traction is the system decided upon.

Sedgley and Netherton.—The electric equipment of these tramways has been inspected by Colonel Yorke, but the final Board of Trade inspection has yet to take place. It is expected that several weeks will elapse before the cars commence running for the use of the general public.

Halesowen.—The British Electric Traction Company are being censured for not having already extended their tramways from Old Hill and Cradley Heath to Halesowen, but we learn that it is very probable that in the near future the tramways will be extended, not only to Halesowen, but also to some of the outlying districts.

Maryport.—Messrs. Dick, Kerr, and Co. propose to obtain powers next session for constructing an electric tramway from Whitehaven to Maryport through Workington, providing the urban and rural authorities will support the project. Two representatives from each town are about to confer in the matter with the company.

South Shields.—Some dissatisfaction is expressed about the fact that the Board of Trade have sanctioned a further five years' lease of the trams. The Corporation's contention is that by waiting for a while they will gain experience, and eventually benefit by the working of the tramways by electric traction in the neighbouring boroughs.

Greenock.—At Tuesday's meeting of the Police Board the master of works and Mr. Nelson, electrical engineer, gave explanations upon the plans of the proposed reconstruction of the tramways within the burgh. It was agreed that after the full specification and detailed plans had been received and considered by the two officials there should be a further report to the committee.

Central London Railway.—Amongst the improvements now being made we note that electric communication is being established at some of the stations between the platforms and the booking halls, so that a signal may be made to the lift attendant indicating the approach of a train, this arrangement being needed to regulate the number of passengers who shall be allowed to descend to the platforms. The daily average of passengers on the railway has already reached a total of about 100,000.

Norwich.—The Newmarket-road tramway route was opened on Friday. On Saturday there were 38,660 passengers on the system, and on Sunday 32,285, nearly 6,000 more than on the previous Sunday. On Sunday evening a serious collision between two of the cars in St. Andrew's was only just averted, and on Monday afternoon there was a rather more serious accident near the same spot. It is stated that the brake failed to act, and the moving vehicle crashed into the rear of the stationary car with sufficient force to move the leading car off the metals.

Competition between Rail and 'Bus.—At the meeting of the London General Omnibus Company last week, Alderman Pound, the chairman, referring to the Central London Railway, observed that the effect would be quite temporary and could be met by "adapting the business to divergence of the traffic"—*i.e.*, by taking 'buses off some lines and putting them on others. The teeming population of London, he evidently thinks, is capable of absorbing the accommodation of the "2d. tube," the Underground, and the 'buses, and even then, perhaps, crying out for more.

Ayr.—Mr. Arthur F. Fuller has been asked to draw up a specification and carry out the work in connection with the overhead electric apparatus, with the exception of the designing of the posts, brackets, and section pillars, which is to be done by the town surveyor and furnished to the committee, the drawing up of the specifications for said items to be done by the electrical engineer. The town surveyor has also been instructed to draw up a general specification of the committee's requirements in regard to cars, and to invite tenders by advertisements for plans, specifications, and estimates for 10 cars with complete electrical equipment.

Sheffield.—The temporary shed which the Sheffield Tramways Committee have erected in Queen's-road for the accommodation of electric cars is now in use, and the reconstruction of the Heeley route is almost complete. The Highways Committee have already decided that Shoreham-street shall be paved with granite. The Tramways Committee are in favour of wood. The two committees are therefore in conflict on this matter, and the Council will have to make the final decision. The question of dry seats in wet weather is being debated. On Tuesday a start was made at the top of Hounsfield-road to complete the connection between this point and Broomhill, where already a short section has been laid.

Sunderland.—According to the *Newcastle Daily Chronicle*, another attempt was made to throw one of the Sunderland electric cars off the line on Saturday night. The circumstances were similar to those which marked the previous attempt, a fishplate being placed on the rails in Roker-avenue. An inspector, fortunately, saw the obstruction in time to stop the car reaching it. The Tramways Committee of the Corporation are highly satisfied with the success of the electric cars since they were opened. On Wednesday in last week they took £80 in fares, on Thursday £90, on Friday £55, and on Saturday £142. Saturday was a record day, for 30,000 passengers were carried on the whole system, 25,000 of them being on the electrical section. Including Sunday, the new cars had alone carried about 77,000 people.

Grimsby.—The Street Tramways Company have let their contract for the erection of the electric power station, in Pelham-road, Cleethorpes, in addition to having purchased new electric cars, at a cost of about £700 each. It is anticipated that by the time the season opens next year the cars at Grimsby and Cleethorpes—where the lines are to be extended as far as Brighton-street, at the south end of the promenade—will be running by electricity. The work of laying a double set of rails along Grimsby-road, suitable for electric traction, will be started in October. The station, which is to be acquired by the Urban District Council as soon as that body has the necessary power to purchase, will be so constructed as to permit of considerable extension, it being the Council's intention to build in conjunction with it the plant necessary for the purpose of street-lighting. It is the purpose of the Council to light by arc lamps the whole of the road along the tramway route, while negotiations with the Great Central Railway for the lighting of the Cliff gardens, pier, and promenade, by electricity are satisfactorily progressing, it being officially stated that the only question now to be considered is that of terms.

Aberdeen.—The Tramways Committee are recommending that the proposed new tramways and the extension of existing tramways be carried out in the following order: (1) the tramway from Castle-street to the bathing station first to be proceeded with and electrically equipped on the overhead trolley system, with span wires supported by side poles on the section between Castle-street and the east end of Constitution-street, and by centre poles on the remaining section eastwards to the bathing station; (2) the section of the existing tramway in Union-street, between St. Nicholas-street and Castle-street, to be electrically equipped on the overhead trolley system, with side poles and span wires; (3) the burgh surveyor to be authorised to invite tenders for the supply of 800 tons of steel rails and 10,000 tons of causeway setts, and the electrical engineer to invite tenders for the poles for the tramways to the bathing station, and for the section in Union-street (between St. Nicholas-street and Castle-street), and also for side poles for the King-street and Great Western-road sections. The electrical engineer and the superintendent of the tramways are about to report as to the type of car to be adopted, and the number to be ordered. They are asking the Westinghouse Electric Company for quotations of the cost of electrically equipping the tramway in Union street on the underground conduit system. The Council are about to make a trial of an automatic life-guard and dry-seat equipment—inventions that had favourably impressed a deputation who had visited the International Tramways and Light Railways Exhibition in London.

Moss Side (Manchester).—At the last meeting of the Moss Side Urban District Council the following terms, which had been arranged between the sub-committee and the Tramways Committee of the Manchester Corporation with regard to the electric

Digitized by Google

tramways in the Council's district, were agreed to: "(1) The Moss Side Council to grant to the Corporation a 21 years' lease of the tramways within the Moss Side district from the expiration of the lease to the Manchester Carriage Company; (2) the Corporation to undertake at their cost to reconstruct the tramways now owned by the Council, and to erect the overhead equipment thereof, and to repair and maintain the permanent way and overhead equipment during the lease, and to renew the rails during the last six years of the term, and to hand over the permanent way in good condition to the Council at the end of the lease, but the overhead equipment shall remain the property of the Corporation unless the Council determine to purchase it; (3) the rental for the lines now owned by the Moss Side Council to be at the rate of £400 per mile of single track per annum; (4) the line in Upper Chorlton-road, within the Moss Side district, now owned by the Manchester Carriage Company, shall be acquired by the Moss Side Council, and the lease of that line shall be on the same footing as leases of similar lines in other districts, which, shortly stated, is that the cost incurred by the Moss Side Council in acquiring and relaying the line according to the Manchester Corporation specification and otherwise shall be refunded by a series of annual payments during the term of the lease; (5) the lease of all the lines to terminate at the same time; (6) no advertisements to be allowed inside the cars.'

Leeds.—An electric car made a trial run over the Hunslet line on Monday. Councillor Smithson (chairman of the Tramways Committee), Alderman Lawson, Mr. Wharam (general manager), Mr. Jeken (assistant electrical engineer), Mr. Livesey (representing the Thomson-Houston Company), and Mr. Laing (of the firm of Messrs. R. W. Blackwell and Co., London, who erected the overhead wires), took part in the proceedings. At a subsequent meeting, Mr. Smithson reported that the Hunslet line was now ready for electric traction, and that the cars would commence running from Briggate to Thwaite-gate on Thursday morning (yesterday). The Tramways Committee on Wednesday decided to recommend the Council to seek powers under the proposed new Tramways Bill to construct the following lines: a tramway to connect the Kirkgate and New York-street tramway with the Vicar-lane and New Market-street section; a tramway branching out of the existing one at the junction of Victoria-road and Meadow-lane, thence along Victoria-road, School-close, and Bishopsgate-street, joining the existing tramway in Wellington-street; a tramway to connect the Infirmary-street tramway with the one in Wellington-street, by way of the short street in front of the Post Office; a tramway commencing at the junction of West-street and Kirkstall-road, thence along West-street and St. Paul's-street, and joining the Infirmary-street tramway at the junction of St. Paul's-street and Infirmary-street; a tramway from West-street to Wellington-street, by way of St. Philip's-street; a tramway commencing at the existing tramway at Chapeltown, and extending along the Harrogate-road to the junction of Street-lane, thence along Street-lane to join the existing tramway near the Canal Gardens at Roundhay. The above lines do not include the whole scheme of extensions which the committee have in view. They have, however, to consider the time at the disposal of the Corporation officials before the Bill has to be deposited in Parliament, and believe that it would not be possible to complete the necessary work in the way of the preparation of the plans, etc., for more extensions than those named. If it should be found necessary, from want of time, to leave out one of the proposed extensions, the line from Chapeltown to the Canal Gardens would be postponed until another Bill was promoted in Parliament.

Darlington.—Since the opening of the Stockton and Middlesbrough electric tramways the public of Darlington have been looking forward to the time when their present system of horse traction should be replaced by a system of electricity. Negotiations were opened with the Imperial Tramways Company, and an enquiry was held by the Light Railway Commissioners, at which the Corporation and the tramways company agreed as to the terms on which Darlington should be put in possession of 10 miles of electric tramways, at a cost of £120 000. The only point on which it seemed likely that there would be any difference of opinion was that of the supply of the current, the tramways company favouring a method by which the current should be transmitted from their existing works at Stockton, and the Corporation desiring to supply the motive power from their own generating station in Darlington. Prof. Kennedy was called in to advise and report as to the price he considered reasonable should be paid by the tramways company for such supply. The secretary to the Commissioners wrote to the Corporation enquiring whether any agreement had been come to, and he was informed that the company had agreed to take electrical energy from the Corporation. An interview was arranged between the secretary of the Commissioners and representatives of both the Corporation and the tramways company, at which it was stated that the Corporation would not have supported the application of the company at the enquiry before the Light Railway Commissioners in the manner they did had there been any suggestion that the company would seek a modification of the original scheme. The Corporation attached much importance to the arrangement to supply the company with electrical energy. The secretary to the Commissioners intimated that they would possibly grant an extension for the laying down of a considerable portion of the system. Another disputed point here arose as to the allocation of a sum of £5,000 which the company had agreed to contribute towards the cost of street widening. After the conference the company's representatives intimated that, though they were not prepared to do anything further towards street widening, they would hand over the provisional order, when obtained, to the Corporation, and dispose of the present tramway undertaking upon advantageous terms. Much correspondence ensued, and eventually the Corporation thereupon resolved that the Commissioners be informed that in the event of the company not being prepared to carry out the scheme, the Council would make application for a new order at an early date. The matter is thus at a deadlock, neither party showing any disposition to recede from the position taken up.

LIGHTING AND GENERAL.

Wrexham.—The work of laying the electric cables has been commenced.

Wimbledon.—It is reported that already an equivalent of 19,000 c.p. lamps has been applied for.

Worksop.—The Board of Trade have approved of the system proposed to be applied for the supply of electric energy.

Colchester.—The Standard Ironworks, which were visited by the Ipswich engineers last week, are lighted by electricity.

Blackpool.—The Corporation were fined last week 40s. for permitting a black smoke nuisance at the electricity works.

Glasgow.—The new tariff of charges, contained in the report published in our last issue, has been adopted by the Council.

Nantwich.—The Electric Lighting Sub-Committee of the Urban District Council are engaged in preparing a report *re* lighting.

Blairgowrie.—The London Electric Company have offered to send a representative to discuss the electric lighting of the town.

Ballymena.—Mr. McCarthy's lighting scheme, which is now being discussed by the Urban District Council, is estimated to cost £6,000.

Derby.—Mr. W. A. Ducat has held an enquiry into the application of the Borough Council to borrow £730 for a condenser in connection with the electric lighting.

Napier Motor Co.—This Company has been registered with a capital of £100, the object being to carry on the business of electrical and mechanical engineers, etc.

Telephone Services.—A conference of authorities within the Salford exchange area of the National Telephone Company is to be held at the Salford Town Hall on Sept. 12.

Newton-in-Makerfield.—The Council object to, and will oppose, if necessary, the proposed application of the South Lancashire Electric Supply Company, Limited, for a provisional order.

London Gazette.—The last day for receiving proofs in the estate of H. Sewell, Clifton-place, Shipley, Yorks, is Sept. 5. Mr. J. A. Binns, official receiver, 31, Manor-row, Bradford, is trustee.

Brighouse.—The North British Electrical Supply Company have decided to cancel their application for powers to supply electrical energy for public and private purposes in Brighouse.

Hampton Wick.—An interview has been arranged between the Lighting Committee and the representative of the Twickenham and Teddington Electricity Supply Company on the subject of the supply of current.

Barnstaple.—The Electric Lighting Act empowering the Council to light the district by electricity having received the Royal assent, the Council are about to engage an expert electrical engineer to advise them.

Leeds.—The Lighting Committee will recommend the Town Council, at its next meeting, to abolish the charge for meters used in connection with the supply of electricity from Oct. 1. It is not proposed to make any alteration in the price.

Oban.—The Town Council have decided to apply in the ensuing session to the Board of Trade for a provisional order to supply electrical energy for public and private purposes within the burgh. A committee will be appointed shortly.

China Cables.—The Eastern Extension and Great Northern Telegraph Companies' submarine cable between Chefoo and Taku is now open for traffic, and arrangements have been made for the early laying of a cable between Chefoo and Shanghai.

Ilford.—The Urban District Council intend to contribute £350 towards the cost of laying the telegraph wires underground, from the bank in the Broadway to Green-lanes, the postal authorities having agreed to make the alteration on that condition.

Bexhill.—At the last meeting of the Urban District Council it was said that the question of free wiring would have to be faced in the future, as the progress of electric lighting was retarded because landlords provided gas fittings in their houses free of charge.

Dover.—At the meeting of the Town Council last week, the Surveyor reported on the notice of the Dover Electricity Supply Company to extend their mains to Victoria Park. He recommended that they should be laid in the road, as cellars projected under the footway.

Rathmines.—We are informed that at the request of the Lord-Lieutenant of Ireland, who is at present confined to his bed, the Electric Lighting Committee have postponed the opening ceremony from the 24th inst. to Friday, Aug. 31, when the arrangements will be carried out as originally proposed.

Ebbw Vale.—The District Council are taking steps to carry out their previous resolution to apply for a provisional order for power to supply the district with electric lighting. The Council's opposition to the South Wales Electrical Power Distribution Bill has resulted in very advantageous concessions.

Hotel Cecil, London.—In consequence of the building of the north block the electrical installation is being largely extended under the superintendence of the chief engineer, Mr. W. A. Poynton, A.I.E.E., and a fifth 75-kw. turbo-dynamo has been ordered from Messrs. C. A. Parsons and Co.

Digitized by Google

Rogers and Gowlett, Limited.—This Company has been registered with a capital of £10,000, the object being to acquire the business carried on by Rogers Bros. at Watford, and to carry on the business of ironmongers, electricians, etc.

Mordey-Fricker Electricity Meter Co.—This Company has been registered with a capital of £20 000, the object being to acquire the inventions of W. M. Mordey and G. C. Fricker relating to improvements in electricity meters, and to carry on the business of electric meter manufacturers, electricians, etc.

Paris Exhibition.—We learn that besides the awards mentioned in our list, the Parsons Marine Steam Turbine Company have obtained the grand prize in Class 33 for materials and plant used in the mercantile marine, and gold medal in Class 118 for naval construction. Those classes we have not noticed.

Carlisle.—The Public Lighting Committee of the Town Council have accepted a proposal by the tramways company to attach lights to four centre poles in Church-street and nine in Lowther-street, and referred the question of lighting the remainder of the centre poles in the streets of the city to a sub-committee.

Aberdeen.—The Corporation tramways traffic returns for the week ending 18th inst. were £876. 5s. 8d,, as compared with that ending Aug. 18, 1899, of £704. 14s. 8d., showing an increase of £171. 19s. The total receipts for the half-year were £8,614. 10s. 3d., and those for the corresponding period, 1899, £7,585. 19s. 10d.

Tunbridge Wells.—At a recent meeting of the Electric Lighting Committee, it was stated that the committee are not going to undertake any extension of public lighting until the new plant is working, but that they would make special arrangement for the illumination of the Pantiles at the concerts for the opening of the new bandstand.

Boness.—The Police Commissioners have agreed to meet a representative of the North British Electrical Supply Company, South Shields, with regard to that company's intended application to the Board of Trade for authority to supply electrical energy for public or private purposes within the jurisdiction of the Commissioners.

Walsall.—The total number of consumers supplied with electric light on July 31 last was 167. The total units generated at the station during the month of July was 19,550. The total output from the main generators was 18 424 units. The total units from the transformers was 14,083. The total units registered on the meters was 13,235.

Brecon.—At the quarterly meeting of the Town Council the Mayor (Colonel Morgan) announced that he had obtained a provisional order for the electric lighting of Brecon, and was prepared to present a copy of it to the Council. A hearty vote of thanks was accorded the Mayor for his generosity in obtaining the order, at a cost to himself of £500.

Greenock.—The Police Board on Tuesday adopted the following motion: "The Board approve of the scale of charges proposed by the electrical engineer, except that the minimum charge for power and lighting combined be 4½d. and 1½d., and that the charge for power only be at the rate of 4d. and 1½d. on the Brighton system, the scale of charges to be subject to revision by the Board."

Stock Exchange.—The Stock Exchange Committee have appointed Aug. 29 as a special settling day for Calcutta Electric Supply Corporation's further issue of 10,000 shares of £5 each, 10s. paid, Nos. 20,001 to 30 000, and have ordered National Telephone Company's further issue of 100,000 ordinary shares of £5 each, fully paid, Nos. 490,001 to 590,000 to be quoted in the official list.

Aberdeen.—At a recent meeting of the Gas and Electric Lighting Committee of the Town Council the question of the erection of the proposed new electric lighting station was under consideration. The committee decided to endeavour to obtain the whole of the Millburn street site for the erection of the electric lighting station, rather than that both Millburn-street and Dee Village-road should be broken up.

Buxton.—At a recent meeting of the Electricity Committee of the Urban District Council, Mr. Jenkins explained the result of his visit to Messrs. Mather and Platt's works, and of his conference with Messrs. R. Hornsby and Sons in reference to the machine stokers, and said Messrs. Crompton would adjust the cut-outs of the arc lamps. The cables for Burlington-road will be proceeded with next week.

Hull.—From the statement of receipts and expenditure of the Municipal Corporation and Urban Sanitary Authority from April 1, 1899, to March 31, 1900, just published, we note that the capital expenditure on the electricity works during the year amounted to £38,843. 9s. 11d., the income was £19,290. 12s. 7d., the expenditure came to £17,366. 9s. 3d., leaving £1,924. 3s. 4d. to be placed to the reserve fund.

Vote Recorder.—Mr. Howe is showing at 332, Strand an ingenious contrivance by means of which votes are printed by levers pulled by the voters. The tedious and so often incorrect process of counting is entirely avoided, and elaborate and apparently efficient means of secrecy are provided. Members of municipal bodies will be interested in this view, which is to remain open for some time.

The City (London).—The Finance Committee of the City of London Union are considering a specification of Mr. Collins, 62, Broad-street, for an electric installation and ventilation at the Board offices. The amount is £533. 10s., £250 of which is for the installation. It includes two ventilating fans, at an estimated cost of £70, to be placed in the windows over the entrance doors. The illumination of the whole building would require 300 lights.

Andes Development Co.—This Company has been registered with a capital of £100,000, the object being to adopt and carry into effect an agreement expressed to be made between the Peruvian Corporation, Limited, and a second agreement made with the Central Railway of Peru, Limited, for the acquisition of railways, tramways, telegraph and telephone systems, etc.

West Riding.—With regard to the notifications from electrical syndicates received by a number of urban councils in the West Riding of intention to apply for powers to supply electric light in the various districts, the *Yorkshire Post* says there is a feeling in some quarters that the authorities should themselves have this power in their own hands, and we understand that a joint meeting of the councils is being arranged to consider the whole question.

Theft of Wire.—At Govan Police Court on Friday, before Bailie Anthony, Arch. Walker, electrician, 16, Garscube-lane, Glasgow, was charged with having stolen 7lb. of lead-covered electric cable from the new Municipal Buildings, Govan. Accused was working at the buildings when he appropriated the wire, stating, when called to account, that he was entitled to take it. He pleaded guilty, and was fined £1. 10s., with the option of 21 days in prison.

Kingstown.—The Urban District Council at an adjourned meeting last week adopted the interim report of the Electric Lighting Committee, which recommended the Council to oppose the application of Messrs. Porte, Sykes, and Co., should it be made to the Board of Trade, asking for a provisional order to light Kingstown by electricity. The Council propose to apply for a loan for the purpose of providing the installation under their own order.

British Motor Traction Co.—This Company has been registered with a capital of £1,000,000, the objects being to adopt agreements made between the British Motor Company, Limited, and this Company; between the British Motor Company, Limited, and H. J. Lawson and this Company, between the British Motor Company, Limited, and J. Harris and this Company; and between the British Motor Traction Company, Limited, and S. F. Edge and the present Company, and generally to carry on the business of electricians, etc.

Blackrock.—At the next meeting of the Urban District Council the following motion is to be discussed: "That any scheme for electric lighting within Blackrock urban district be undertaken by this Council and not by outsiders, and that a conference be held with the Kingstown Urban District Council to ascertain what action they have decided upon for the lighting by them of their district, and also to discuss with them the feasibility or otherwise of a joint scheme of electric lighting for the two urban districts of Kingstown and Blackrock."

Scarborough.—Some correspondence has passed between the Scarborough Electric Supply Company and the Corporation as to the terms of purchase of the undertaking. The company at first objected to referring the terms of purchase to arbitration, and suggested that negotiations should proceed on the basis of the present and future profits of the undertaking, and that a small committee be appointed to discuss the matter. A deputation has now been appointed by the Town Council to meet a deputation of the electric supply company.

Consett.—The Urban District Council are considering the question of lighting the district with electricity. At a special meeting on Monday a deputation on behalf of the Northern Counties Electrical Supply Company asked the Council's consent to a provisional order from the Board of Trade to lay down plant, with the object of supplying the district with electricity for lighting and other purposes. The chairman was adverse to the Council giving away its rights, but favoured the idea of the Council supplying its own electricity. The subject was ultimately referred to the Gas Committee to consider the matter in detail and report to the next ordinary meeting of the Council.

Appointments Vacant.—The Corporation of Eccles invite applications for the appointment of borough electrical engineer at a commencing salary of £200 per annum.—The Borough of South Shields require two shift engineers (£104 per annum).—The Dundee Town Council have a vacancy for improver (commencing salary, £52 per annum). Full particulars of these vacancies appear in our advertisement columns.—The Tramways Committee of Darwen require the services of a working foreman to take charge of the electrical equipment of the cars and overhead equipment under the electrical engineer. Applications, endorsed "Tramway Foreman," with testimonials or references, to be sent to Mr. W. P. Halliwell, town clerk, Darwen, by noon on 29th inst.

Chester.—Lieutenant-Colonel A. C. Smith, R.E., held an enquiry on Wednesday into the application made by the Chester Corporation for sanction to borrow £35,000 for the purpose of extending electric lighting in the city. The Town Clerk explained that the loan was for new machinery, extension of the station, engine-house, and anticipated requirements for extension of the mains and providing service for lamps. So far the undertaking had proved an unqualified success, and out of the revenue the Council had been able to pay off all preliminary expenses, which were not included in the previous loan. They had placed to the reserve fund a sum of £2,465 1s. 1d., and reduced their original price of 6d. per unit to 4½d., and in addition to that the committee were clearing a considerable discount to large consumers. During the last three years 355,957 units, 473,656 units, and 617,792 units respectively had been sold. The public lamps had increased from 83 to 361: 165 of these are arc lamps. It was not absolutely settled, but most probably they would be able to work the trams (which the Corporation propose to take over) by electric traction, and the Corporation would be able to generate the electric energy at the present station.

Digitized by Google

Soothill Nether.—At a meeting of the District Council the opinion was expressed that the electric light would be more expensive than gas. The question was also raised as to whether the British Electric Traction Company, and the Northern Counties' Electricity Supply Company, Newcastle-on-Tyne, would supply electricity for illuminating purposes or whether they only provided electricity for traction purposes. It was agreed to write to the Thornhill Council asking whether the companies named supplied electricity for lighting purposes.

Stockport.—The Theatre Royal has just been fitted with electric light upon the three-wire system. Owing to the fact that the voltage of the Corporation supply is too high for stage work, a special rotary transformer has been provided for the stage lighting, which transforms the electric current from 230 to 75 volts. There is a gamut of three colours—white, red, and green. The lighting throughout has been done by Messrs. Robert Dawson and Sons, of Stalybridge, to the specifications of Messrs. Bamford and Halstead, consulting electrical engineers, of Manchester.

Arbroath.—The Gas Corporation have had under consideration an application from a manufacturing firm in the town to be allowed to carry an electric wire from their works to their private residence. The Corporation are considering the advisability of introducing the electric light themselves, and it was remarked that this application raised the question as to whether overhead or underground wires should be allowed to be laid in connection with the streets of the borough, or whether private parties should be allowed to cut up the streets. The question is now before the Electric Committee for report.

Friern Barnet.—The District Council have decided to obtain a provisional order authorising them to light the district by electricity. The scheme is yet in embryo, and the suggestion at present is to schedule only the two main roads in the district, Station-road and Friern Barnet-road, for immediate lighting, and to add other roads as occasion and opportunity arise. This plan would give a very small area to start with, so small that the cost—initial and working—could not, in our opinion, be justified by the return. The Council have declined to go in with Tottenham for a joint scheme.

Halifax.—The accounts of the Corporation electricity works for the year ended March 31 show that the expansion of this department has exceeded expectation. The output has been more than doubled, the number of units sold being 1,371,333, as compared with 628,759 in the previous year. The lamps connected number 45,403, as against 32 020; the gross revenue was £16 069, as against £8,957—an increase of £7,112. The gross profits amounted to £9,001, as compared with £4 565 last year—an increase of £4,436. The average price obtained per unit, after deducting discounts, is 2·77d., as against 3·33d. last year. It is reported that the electrical engineer (Mr. Street) has had an offer from a Lancashire borough of £500 a year.

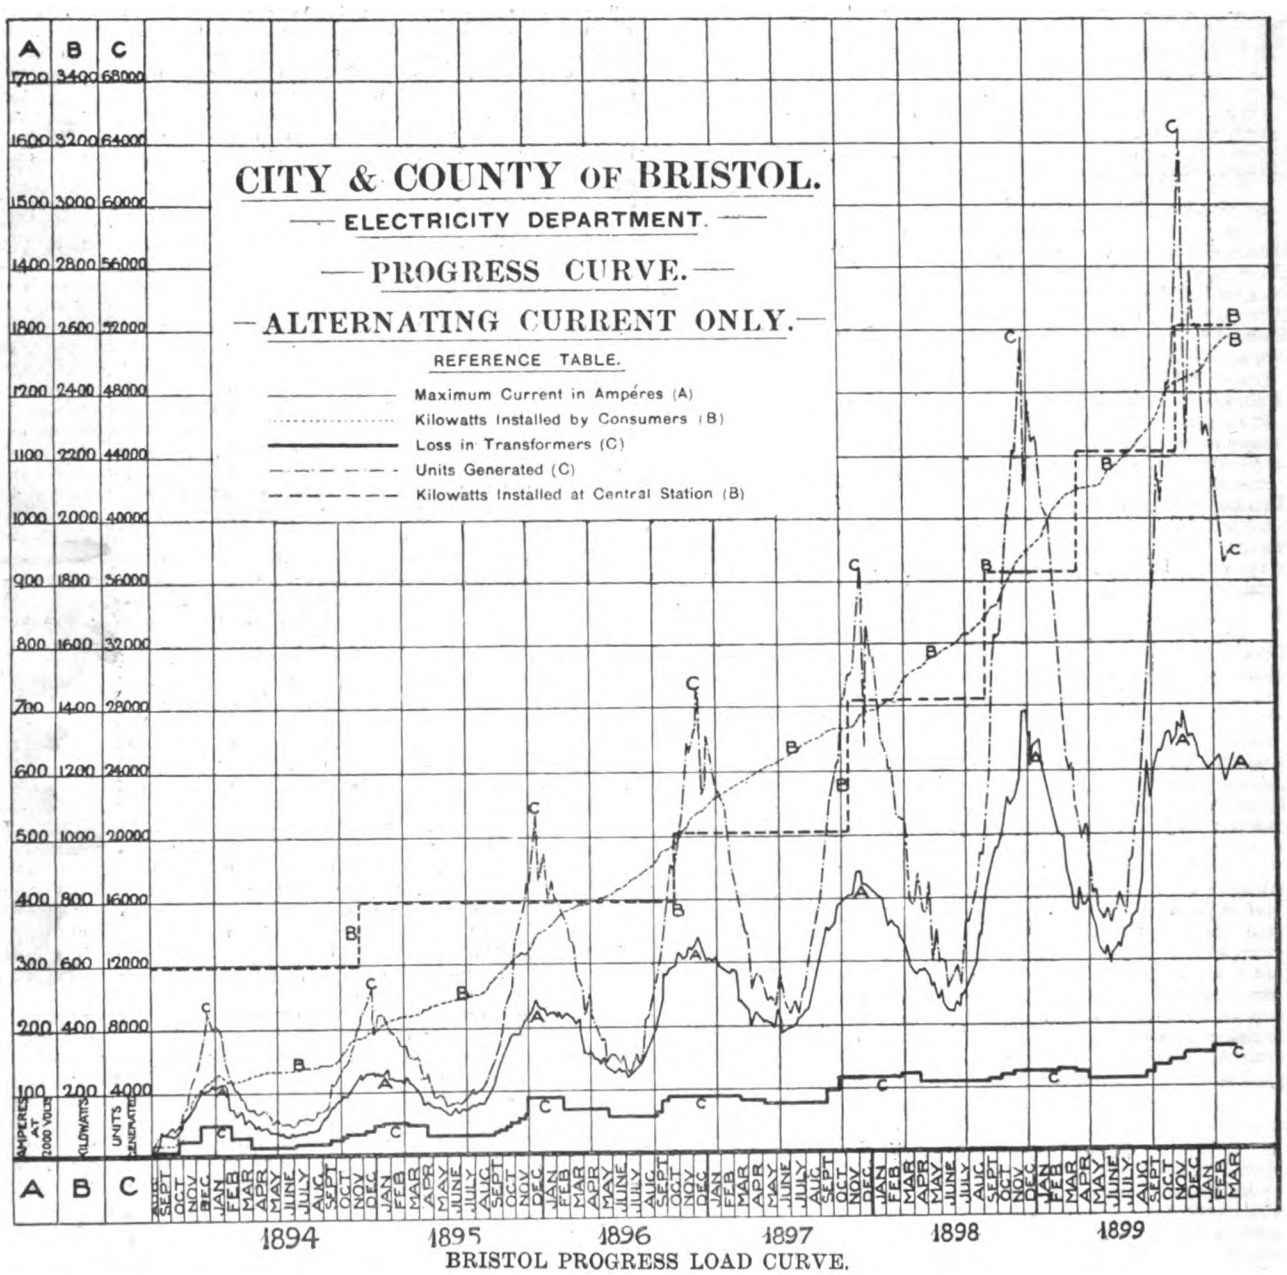
Llanelly.—There is now nothing in the way of the scheme for providing Llanelly with a system of electric light and traction going forward. There has been some delay owing to the inability of the British Insulated Wire Company to arrive at a settlement with the proprietors of the existing tramways. This week terms have been agreed upon between the two companies by which the British Insulated Wire Company will purchase the undertaking of the Llanelly Tramways Company. The scheme is a very elaborate one, and will entail a cost of close upon £100,000, all of which is to be provided by the company. It is proposed to establish a system of electric cars not only for the town, but also to the outlying districts of Pwll, Felinfoel, and Llwynhendy. In addition, there will be a complete installation of electric light, thus bringing Llanelly into line with the largest towns in the country.

Sydenham Explosion.—The following account of the inquest appeared in the *Daily Chronicle*: "The deputy-coroner for West Kent, who had the assistance of Mr. J. Owner, factory inspector, resumed at Lewisham the inquest on the bodies of Frederick Elliston, 33, and William Philbrook, 19, who met their deaths in a boiler explosion on the premises of the Crystal Palace District Electric Supply Company on the 25th of last month. Evidence was given by Mr. Walter Phillips, electrical engineer to the company. He said that every year until this year the boiler had been thoroughly examined. The reason why it was not done this year was because the company were busy and could not let the boiler be idle, as the examining process took over a week. Since the explosion witness had examined the fragments of the boiler and found a flaw. In his opinion, that flaw was the cause of the explosion. After further evidence had been taken the jury returned the following verdict: That the deceased men died suddenly from injuries caused by an explosion of a boiler due to its defective condition, which might have been discovered had the boiler been thoroughly examined, as it ought to have been, between April of last year and the date of the explosion.

Blackburn.—A Local Government Board enquiry was held on Friday into an application of the Corporation to borrow £190,000 for electricity extension purposes, including lighting and power. The present scheme will carry the Corporation on for four or five years, when they will still have land available at their proposed new works for an even larger scheme. The Town Clerk explained that it was originally proposed to ask for £220,073 for the purpose of electricity extensions, but that amount had been reduced to £189,699. The electricity works adjoined the No. 1 gasworks, which were very old, and had become too small to meet the needs of the town. The Corporation had purchased land in another part of the town for new gasworks, and when these were completed the whole of No. 1 gasworks would be devoted to electricity purposes. The site had been valued at £30,000. Mr. Lacey, consulting electrical engineer, commenting upon a number of the points of the scheme, said part of the scheme would meet the requirements of the borough for the next four or five years, and the borrowing powers now sought would cover the expenditure for that period. The electricity extension included lighting and power, whilst after the present portion of the scheme had been carried out there would be land available for further extensions for another 15 or 20 years.

Battersea.—The people, with a big "P", had a field day at Battersea on Saturday last, when the chairman of the Vestry, Mr. Mathews, J.P., laid the foundation stone of the electric light station at Lombard-road. Mr. Willis, the chairman of the Lighting Committee, who presided, in a few clear words gave a description of the scheme. He said that out of the 13 miles of mains proposed to be laid 11 miles had already been laid, and the committee expected the building to be ready by November next, and to be able to supply current by May, 1901. They also intended to supply private lighting at the rate of 5¾d. per unit on the free-wiring system. Great stress was laid on the fact that all the work was being carried out under the direct employment system. As a matter of fact the buildings are being erected by the Works Department of the Vestry, from the designs of Mr. C. Stanley Peach, F.R.I.B.A., of 28, Victoria-street, Westminster, S.W., under the surveyor (Mr. J. T. Pilditch) and the general foreman (Mr. L. J. Howell). From notes by Alexander B. W. Kennedy, LL.D., F.R.S., the consulting electrical engineer, we gather that the Battersea central electric light station has been designed so that when it is complete it may contain about 14,000 h.p. in boilers, engines, dynamos, etc. In the first instance, however, it is proposed to build only a portion of the station, and in this portion plant is to be placed to the amount of about 1,500 h.p., which, if all working at once, is sufficient to supply current for about 25,000 lamps of 8 c.p. alight, besides 240 arc lamps in the streets. Allowing, however, for the necessary reserves, it is intended that this plant should supply current for about 17,000 lamps of 8 c.p. alight (or about 45,000 lamps wired), besides the street-lighting. The boilers which are now being placed in the station are of the Babcock tubular type, and will work at a steam pressure of 200lb. per square inch. They supply steam at this pressure to the engines, which are of the triple expansion type, and are intended to work with condensation. Each engine drives one dynamo direct without intermediate gearing. The engines are being made by Messrs. Willans and Robinson, Limited, of Rugby, and the dynamos by Messrs. Mather and Platt, of Manchester. A large battery made by the Hart Accumulator Company, of Stratford, having a capacity of 1,000 ampere-hours, will be placed in the station to assist in the regulation, and also as a means of supply during hours of light load. The current generated by the dynamos is to be distributed throughout Battersea at a pressure of 460 volts, the mains being arranged on a three-wire system, so that the lamps work at 230 volts. The current is of the continuous type, so as to be directly suitable for power as well as for lighting. The mains are being laid at once of a section sufficient to supply current to a total of about 60,000 lamps wired. The distributing mains are laid throughout in troughs filled solid with bitumen. The trunk or feeder mains are chiefly laid on the same system, and partly also as concentric armoured cable. The whole of the main-laying is in the hands of the Callender's Cable and Construction Company, Limited, of Erith, but the work of opening and reinstating the highways is being done by the Vestry's own workmen. There are at present being placed in the streets 240 arc lamps, which are to be supplied 10 in series from the outer mains of the distributing system. These lamps are placed in the streets at about 65 yards apart, and carried on special posts, so that the height of the lamp above the ground is about 23ft. The tenders accepted for all the engines and appliances, and the whole system of mains, amount to £57,800. Then Mr. Mathews took hold of the silver trowel presented to him by Prof. Kennedy, the consulting engineer of the Vestry, and launched out in statistics. We were pleased to hear that all municipal electric lighting undertakings paid well, with one exception, and had no idea that the current sold in Edinburgh at 3¾d. per unit cost only 1½d. But Mr. Mathews said so. It is true Prof. Kennedy afterwards explained that another 1½d. or so would have to be added to this 1½d. on account of amortisation charges. But Mr. Mathews's great point was that municipalities made enormous profits out of electric light undertakings, while no company did half as well. Therefore, consumers ought to deal only with the former. It did not strike us as particularly good logic—but let that pass. Where we got our first shock was when we heard the proclamation, "In the name of the people of Battersea, I declare this stone well and truly laid." To one familiar with similar proceedings this savoured very much of 1793, red caps, disestablishment of the deity, etc. Mr. Mathews was followed by Mr. Burns, the present member of Parliament for the district, who let forth a violent diatribe against all and every opponent of municipal trading. These opponents consisted either of ignorant or of interested persons; well-informed and disinterested persons like himself, so he said, knew that it was the best thing for the people, and he dared both Houses of Parliament to interfere with the municipal authorities in that respect. Mr. Burns, as might be expected from a particularly well-informed and a particularly disinterested person, then had a deal to say about company-mongers who scooped in the profits, ignorant local scribes who ought to be at the treadmill, etc. This was interlarded with some statistics which were quietly brushed aside in subsequent speeches by Mr. W. Manser and Prof. Kennedy. What Mr. Burns did not tell his audience was that the "company-monger" and the company shareholder, who is generally also a

Digitized by Google



BRISTOL PROGRESS LOAD CURVE.

ratepayer, risks his own money, while the vestrymen openly gamble with the credit or the purse of the ratepayer. Furthermore, a company has not the same amortieation charges to meet, and should, therefore, be able to supply cheaper light. It is true that these charges cease after 25 or 30 years, when we are dead, and when the machinery is either useless or superseded. So there is more than one side to the question; and vote-catching, patronage, and nepotism for the leaders, and the Government stroke for their clients might be mentioned as appertaining to that so much advocated by some particularly well-informed and partially disinterested persons. Mr. Manser said that the Moderates in the Vestry had opposed the idea on the ground that thereby every ratepayer was made, whether he wished or not, a shareholder in a trading enterprise, to which, naturally, some risk was attached. They, however, had given in after the wish of the people had been ascertained. Mr. C. Stanley Peach, F.R.I.B.A., the architect, gave some particulars of the buildings now in course of erection. They are situated at the junction of Lombard-road and Holman-road, the frontage to the former being 186ft., and to the latter 64ft. 3in., and comprise the offices connected with the central station, an engine-room 90ft. by 71ft., a boiler-house 123ft. by 64ft., coal store 80ft. by 64ft., battery-room 63ft. by 20ft., and ample stores for mains department and meter-testing room. The chimney is octagonal in shape, measuring 25ft. 6in. by 25ft. 6in. at the base, and 13ft. 6in. by 13ft. 6in. at the top, and when finished will be 194ft. high above the ground. The foundation is 28ft. below the street level. The total height of the shaft from bottom of foundation to top of cap is therefore 222ft. The walls, externally, will be faced with picked stock bricks with blue brick strings and dressings, and the interior of the walls will be faced with blue bricks, with white and brown glazed bricks in those rooms in which cleanliness and light are of importance. Above the office portion of the buildings apartments are provided for the engineer in charge of the station, and also for some of the staff. The buildings, which will cost about £50,000, will contain all the latest improvements, and in the part now being built provision is made for erecting from time to time additional machinery and plant as the demand for current increases.

Then some more speeches followed, the band of the 4th V.B. East Surrey Regiment (by kind permission of Lieut.-Colonel T. Tully, commanding), under the direction of Mr. A. R Spriggs, played a few more selections of popular music while the people perambulated around the newly-laid stone, and then betook themselves into the refreshment tents, where ample food and drink was provided, and even tables and chairs to enable them to enjoy the same in peace and comfort. In fact, everything, from the substantial scaffoldings, the large marquees, the band, down to the programme with its coat-of-arms, was on the most lavish scale—probably in anticipation of the future profits of the undertaking.

Total maximum possible demand (kilowatts)		2,733

Number of public lamps, 308 arc and three incandescent.

PROVISIONAL PATENTS, 1900.

August 13.

14449. Improvements relating to double-pole, three-way, and similar electrical switches. Ernest Edward Bartlett, 10, St. George's-crescent, Liverpool.

14450. Improvements relating to electrical controlling and regulating switches. Ernest Edward Bartlett, 10, St. George's-crescent, Liverpool.

14458. Improvements in telegraphic relays. Charles Edwin Wilson, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14463. Improvements in apparatus for electrolysis. Paul Schoop, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

14488. A method of electrically reversing the direction of elevators driven by electricity. Reginald Haddan, 18, Buckingham-street, Strand, London. (A. Stigler, Italy.)

August 14.

14495. Improvements in or connected with automatically opened switches. Thomas Hesketh, Belvedere, Cheriton-road, Folkestone.

14506. Improvements in and relating to dynamo-electric machinery. Alfred George Brookes, 55, Chancery-lane, London. (Charles Leonard Cotton, United States.) (Complete specification.)

14550. Improvements relating to the insulation of electric conductors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Nikola Tesla, United States.) (Complete specification.)

14552. Improvements in conduits for electric conductors, water, or the like. Hosea Tugby, 47, Lincoln's-inn-fields, London.

14557. Improvements in or relating to conduits for electric conductors. John James Bate, 6, Lord-street, Liverpool.

14558. Improvements relating to the transmission and receiving of telegraphic signals. Georg Friedrich Rudolf Blochmann, 45, Southampton-buildings, Chancery-lane, London.

14568. Improvements in toll-collecting machines for telephones. Reginald Haddan, 18, Buckingham-street, Strand, London. (The American Toll Telephone Company, United States.) (Complete specification.)

14582. Improvements in and connected with electric furnaces. Rámon Chavarria-Contardo, 55, Chancery-lane, London. (Complete specification.)

August 15.

14608. Improvements in electricity meters. Sydney Holmwood Holden and Chamberlain and Hookham, Limited, 4, New Bartholomew-street, Birmingham.

14633. An improved system of electric lighting and apparatus or devices therefor. Pierre Lapertot, Gilbert Villard, and Laurent Pignaud, 6, Lord-street, Liverpool.

14637. Improvements in and connected with apparatus for punching strips of paper and like material suitable for use in telegraphic transmitters and for like purposes, the same being particularly adapted for the preparation of telegraphic messages for automatic transmission over single or duplexed circuits, which may be received in Morse or other telegraphic codes or type-printed characters arranged in page form. William Lloyd Wise, 46, Lincoln's-inn-fields, London (Charles Luman Buckingham, United States.) (Complete specification.)

August 16.

14684. Improvements in or connected with incandescent electric lamps. Herbert Edmund Moul, 8, Hythe-road, Willesden Junction, London.

14691. Improvements connected with electric primary batteries for traction purpose. Samuel William Maquay and Theodore Gervase Chambers, 55, Chancery-lane, London.

14704. Improvements in transmitters for electrical waves or the like apparatus. Carl Gustaf Georg Braunerhjelm, 322, High Holborn, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Jan. 26, 1900, being date of application in Sweden.)

14712. Improvements in apparatus for recording, reproducing, and transmitting sounds. George Edward Gouraud and Horace Leonard Short, Clun House, Surrey-street, Strand, London.

14715. Improvements in and relating to thermo-electric apparatus. William Edward Evans, 27, Chancery-lane, London. (La Société Ginestes et Cie., France.)

14723. Improvements in magnetic cut-out apparatus. Leonard Andrews, 46, Lincoln's-inn-fields, London.

August 17.

14743. Improvements in electric cut-outs and the like. Herbert Fitzroy Clayton, Union Works, Huddersfield. (Complete specification.)

14759. Improvements in electric traction. Edward Henry Tyler and Arnold Greaves Hansard, 15, Kirkstall-road, Streatham Hill, London.

14794. Improvements in apparatus for use in wireless telegraphy. Thomas James Bowlker, 37, Chancery-lane, London.

August 18.

14841. Improvements in means and apparatus for telegraphing and controlling various mechanisms from a distance without wire or other like connections. James Tarbotton Armstrong and Axel Orling, 40, Vartry-road, South Tottenham, London.

Digitized by Google

14798. An attachment to ceiling roses for raising and lowering central-hole weights or fixing electrical fittings. Robert Walter Braham, 54, Farringdon-road, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Sept. 8.

1899.

16569. Accumulator electrodes. Katz.

16926. Electric measuring and indicating apparatus. Darwin, Griffiths, and Whetham.

17504. Means and apparatus for recording the deflections of pointers, magnetic needles, coils, and the like, and the fluctuations of electric currents, and for utilising such deflections or fluctuations to actuate or control various other mechanisms or apparatus. Goddin.

17593. Transmission dynamometers or torque indicators. Morgan.

18365. Central battery telephone exchange systems. Aitken.

18443. Amalgamation and coating of metals or alloys of metals with metals or alloys of metals by the aid of electricity and apparatus therefor. Frederick Foss (executor of the late Frederick Hall Snyder).

20544. Electric bell. Bowman.

20751. Device for steering electrically-driven motorcars. Andreas.

21720. Switches for electric light. Bell and Berry.

22182. Electric cables. Buchanan.

23182. Contact breakers especially applicable to induction coils. Weissmann and Wydts. (Date applied for under International Convention, April 25, 1899.)

23561. Vacuum-tube lighting. Wise. (Moore Electrical Company.)

1900.

246. Automatic electric switches or cut-outs. Headley.

2929. Electrolysers. Chapman and Batt.

5755. Manufacture of electrical insulating material. Jung, Brecher, and Kittel.

6479. Electric accumulator plate. Ribbe.

7166. Electric railways on a surface-contact system. Murphy.

9110. Contact-pieces for transmitting the current from the fixed base to the revolving or swinging top of electric searchlight projectors. Paul. (Paul.)

11026. Cord grips for electric light fittings. Lundberg and Lundberg.

11272. Means of and apparatus for preventing the premature starting of electric motors or the like used in connection with electric lifts. Hofbauer.

11429. Electromagnet of high attractive force. Vogelsang and Lindenstruth.

11659. Electric cut-out plug. Haase and Röder.

11797. Regulating devices for alternating electric current circuits. British Thomson-Houston Company, Limited. (Thomson.)

11915. Trolleys for electric railways or tramways. Tomb.

11991. Rheostats for electric motors. British Thomson-Houston Company, Limited. (Hall.)

12971. Electric switches. Bruce.

NOTES.

South-Western Polytechnic.—We are informed that Mr. William Henry Eccles, B.Sc., and Mr. Charles Frederick Smith, Whitworth scholar, have been respectively appointed to the posts of senior demonstrator of physics and senior demonstrator of electrical engineering at the South-Western Polytechnic, Chelsea.

Electrical Treatment.—It is gravely announced by the *Scientific American* that an ostrich in the Cincinnati Zoological Gardens is undergoing treatment by electricity for paralysis. Under this treatment the bird has been able to swing first one leg and then the other. We trust that a continuation of the treatment will not induce the ostrich to attempt the hazardous procedure of swinging both legs at the same time.

The Associated Chambers of Commerce.—The gathering of the representatives of the Associated Chambers of Commerce in Paris will commence on Sept. 5, and will in this way clash with the meeting of the British Association at Bradford. It is hoped that nearly 500 representatives will proceed to France, where a series of festivities and a little business has been arranged. In the notes in the daily Press great stress is laid on the wonderful dinner which is to take place.

American Institute of Electrical Engineers.—We have received a copy of the June and July number of the *Transactions* of the American Institute of Electrical Engineers. The volume contains an illustrated paper by Dr. F. A. C. Perrine on "The Use of Aluminium Wire and Some Constants for Transmission Lines," and the discussion in New York and Chicago of the paper by Mr. Sachs on "The Evolution of Safe and Accurate Fuse Protective Devices."

Destruction of Aluminium Works.—We are sorry to note that during a tornado recently, the Pittsburgh Reduction Company's aluminium works were almost entirely destroyed. The loss amounts to some £20,000, and the works must be closed for a very considerable period. The engineer of the works was caught by the falling walls and was very seriously injured. The company's works were situated on the banks of the Alleghany River, and covered a space of some 10 acres.

Calcutta Trams.—We are pleased to note that Messrs. Dick, Kerr, and Co. have secured yet another contract in India—namely, that for the electrical equipment of the Calcutta tramways for the sum of £70,000. The Bill for these Calcutta tramways has passed through the Bengal Legislative Council, and the company's tramway engineer has been in Calcutta for some time. These things, taken together, seem to point to the early construction of the tramways, and a speedy disappearance of the horse from the tramway tracks.

Personal.—Mr. Dunn, the superintendent of telegraphs of the Caledonian Railway for the past 33 years, has, we learn, intimated his resignation to the directors of the company. Mr. Dunn's retirement takes effect at the end of October. He has had a long connection with telegraphy, and is one of the oldest telegraph officers in the United Kingdom, and one of the few original members of the Institution of Electrical Engineers. He was also president of the conference of the Railway Telegraph Superintendents and Engineers in 1889.

Indian Electricity.—It is somewhat disappointing to learn that the report which Mr. J. W. Meares was some time since commissioned to prepare as to the feasibility of a scheme of electric lighting by water power for Simla will not be presented for a considerable time yet. One gathers from information received as to the district that a really useful scheme is quite possible. It is also interesting to learn that the Viceregal Lodge at Simla has had an electric installation placed in it, the plant consisting of three Siemens-Willans direct-coupled sets, with also a battery of Tudor accumulators.

Paris Congresses. — Our contemporary *La Mois Scientifique et Industriel* is distinguishing itself in its report of the congresses being held in the Paris Exhibition. Thus in the second part of the volume, which has just reached us, we find a number of valuable abstracts of the communications read before the Physical Congress at the beginning of the present month. These abstracts are quite as, if not more, useful to the scientific man as the full papers, which would be too cumbersome if collected together. The rest of our notes in this issue referring to the congress are translated and condensed from the above contemporary.

The Occlusion of Gases.—Prof. J. L. Howe in his address to the American Association for the Advancement of Science discussed the present knowledge of the phenomena of the occlusion of gases by metals. It is curious that, while the fact that platinum absorbed hydrogen and that it would cause the ignition of the stream of that gas was discovered in 1823, little is known at the present time of the way in which this occlusion takes place. The author showed that other members of the eighth group of metals had similar properties to a certain degree, and lamented that more was not known of the phenomena in question. Prof. Howe had no new facts to add to his historical *résumé*.

A Valuable Patent.—It is interesting to learn that the German Government has just paid some £100,000 to the Strowger Automatic Telephone Exchange of Chicago for the patents and rights to manufacture and use the automatic switch which the company owned. The deal has not taken place without due consideration by the Germans, as a trial was made of it in the earlier part of the year, and £30,000 was paid at that time. The contract at that time was for a 200-instrument exchange to be used by the Government for six months, and if considered satisfactory at the end of that time a further £10,000 was to be paid. The installation, as well as another which was fitted later, has proved a success, and payment has been made as above recorded.

The Progress of Pyrometry.—Mr. C. Barus presented a report to the International Congress of Physics on the 6th inst. on the above subject. In it he reviewed the various systems of measuring high temperatures, such as the alteration it caused to liquids and solids. The use of measurements based on this principle is on the increase. Other methods, such as the determination of temperature by melting points, by ebullition, and by the specific heat of metals, were described; as was also a gas thermometer, which he also states gives very good results. The most accurate method, however, is that devised by Messrs. Callender and Griffiths for ascertaining temperature by means of the variation of the resistance of a platinum wire. The method is well known to our readers, and we are pleased to see the value of it adopted by the International Congress.

The Nernst Lamp.—The Nernst lamps have at last made an appearance in the Paris Exhibition, but, as with the Marconi telegraph at the British Association at Dover last year, they have been left in charge of an untechnical man. This procedure, of course, has an advantage from the owners' point of view, in that they wish to give the public a good idea of the system, but no technical details concerning the same. The lamps on view gave a good

Digitized by Google

light, just as those sent to England some 18 months ago and exhibited by Mr. Swinburne did. The visitor to the Exhibition is, however, given no chance of ascertaining what current they take, and has to believe the statement of the untechnical attendant as to the watts per candle-power. Thus, while the exhibit is exceedingly interesting in experiments on the lighting up of these lamps, it gives no indication that a commercial stage has been reached in the manufacture of them.

Tramway Obstruction.—The electric tramways at Sunderland have now been running for a fortnight or so, and have been subjected to the usual obstruction from idiots in the roadway. Unfortunately, one of the obstructors who might have caused a serious accident has not yet been discovered, although a considerable reward has been offered for information which would lead to his detection. The obstruction referred to was the placing of a heavy railway chair across one of the metals, which might have wrecked an electric car. We are pleased to see that the more usual cases of obstruction are being brought before the police court, and that heavy fines are being imposed against those drivers who refuse to draw to one side to allow the tramcars to pass. A few fines such as have been inflicted will soon convince the owners of the cars that they have not the sole right to the roadway, nor can they obstruct the general public, as they seem to think they may do.

The Marconi Telegraph.—It is stated by the daily Press that the Marconi system of telegraphy is to be extensively used on board the ships of the British navy, in consequence of the fact that it proved more successful than a rival system against which it was tried. The exact purpose for which the navy are to use the system is not stated in the daily Press, nor is mention made of the number of equipments which will be required. We trust that the news is authentic, and that it will console the company for the harsh treatment which they claim to be receiving from the Postmaster-General. The directors, after puffing the system for years as the Marconi wireless telegraph, naturally feel it extremely hard that the Government should look upon it as a system of telegraphing at all. An agitation is being organised by the Dover Chamber of Commerce to get the signalling arrangements between the East Goodwin lightship and the shore reinstated.

Bruges Harbour Construction.—It is stated that in the great works which are now going on in order to make Bruges a good port electricity plays an important part, all the machinery and apparatus being operated by its aid. The electrical plant is driven by energy supplied from a central station containing three Willans compound engines of 500 h.p., driving three dynamos at 500 volts. Some 30 motors are used in connection with the various machines, amongst which are brickmaking machines, band and circular saws, pile drivers, cranes, pumps, etc. The application of electricity is not, however, only temporary, as when the works are finished the rolling lock gates and revolving bridges are also to be worked by motors. The brickmaking machines have a daily capacity of from 160,000 to 200,000, and each is operated independently by a motor. Very heavy work is also carried on in the boiler shop, and the motors in this case have been found to be invaluable.

The Specific Heat of Water.—Prof. C. H. Griffiths reported to the Physical Congress on the above subject. In his report he reviews the work which has been done in determining accurately the value of the specific heat of water and its variation with temperature. He concludes from various determinations that the following is a fair statement of present-day knowledge: If one takes as the thermal unit the quantity of heat required to raise 1 grm. of water from 15deg. to 16deg. C. as measured on the scale of a hydrogen thermometer, then the calorific capacity which should be admitted for 1 grm. of water, as an international basis, should be $4\,187 \times 10^7$. He also concluded that the new experiments which should be accepted for the variation of the specific heat of water should be represented by the curves resulting from the researches of Barnes. He considered that the specific heat of water between 0deg. and 100deg. C. might be considered as equal to the value defined above.

Electric Motors v. Gas-Engines.—We learn from a Sheffield paper that dear coal is conducing to the increase in the number of gas-engines, and that the orders for these small gas-engines to replace steam-engines are at the present time very numerous. In view of the fact that nearly all the gas companies are increasing their rates, we would suggest that those people who intend changing over should approach their Corporation electricity supply department before entering into contracts for gas-engines. We know that in certain of the large towns the electric lighting committees have not yet reduced their tariffs for the energy for use in motors to the point they should do, but in the majority of our large towns electric motors on the public mains will be found more convenient, more economical, and, in most cases, cheaper than gas-engines. The space required is very much less, and, as regards noise and nuisance, a gas-engine will not be tolerated where once a motor has been tried.

Telephone Opposition in Glasgow.—The National Telephone Company evidently intend to make a keen fight for the telephone business in Glasgow against the Corporation exchanges. They are for this reason introducing improvements and new features. One of the improvements is naturally the complete metallic circuit, which, of course, has to be carried overhead, and which, it is said, will be in full working order in a few months time. Of course, we do not know whether the few months' will expire before or after the real competition commences. Another feature being introduced is the use of a single connection for two subscribers. This cheapens the cost of the service, but with it one subscriber only can use the line at one time. It is proposed that as many as eight individuals should be placed on the one wire, in which case it would only cost £3 per subscriber per annum. In the notice which appears in the local papers no mention is made of the fact that one of the eight subscribers could monopolise the wire at an important time and prevent the other seven from speaking.

Electric Tramways and Asphalte Pavements.—Various attempts have been made in Germany to devise a means whereby the destructive influence exerted by the passage of heavy electric tramcars upon asphalte pavements may be counteracted. Hitherto these endeavours have been without definite result, but much has been said lately in praise of a system which is shortly to be subjected to a practical test in Berlin. Contrary to ordinary practice, in which the tramrails are laid immediately upon a foundation of concrete, further resting in direct contact with the superimposed asphalte, the new method consists in laying the rails upon a bed of coarse gravel, and running a line of hardwood blocks along either side. Experience has taught that ordinary pavements, with gravel and stone foundations in place of concrete, offer the greatest resistance to the influence of electric cars. It is assumed that the gravel or stone allows the rails more play, which is advantageous, in that, despite great care in their manufacture, it is impossible to ensure exact uniformity with the gauge of the cars. The new method is also relied upon to reduce the noise caused by the cars running over the lines.

Digitized by Google

Air Storage.—It is stated in a communication by Messrs. Desgrey and Balthazard to the French Académie des Sciences that they have discovered a means of renewing air indefinitely. They propose to use the invention in divers' helmets. The process consists merely in the use of sodium bioxide, which they state has been found to possess the property of absorbing carbonic acid gas in a vitiated atmosphere, and throwing off its oxygen in exchange. Laboratory experiments have been tried with mice, which continued to live under a glass containing a fragment of moistened sodium bioxide, while under similar conditions, without the latter substance, they died by asphyxia. A diving helmet has also been devised of aluminium, coated with sodium bioxide, which enabled the wearer to remain for several hours in an atmosphere which he could not otherwise have breathed. We are inclined to believe that the discoverers of this remarkable property in sodium bioxide have somewhat hastily jumped at conclusions, and are afraid that the diver who took a few hours under water on the strength of this discovery would never dive again.

Electric Tree Felling.—We gather from the *Electrical World* that a large elm tree 42in. in diameter was recently cut down at Jacksonville, Illinois, by means of an electrically-heated wire. This tree, which proved to be slightly too large for a cross-cut saw which was available, was handed over to the electrician of a large public institution in the neighbourhood. He used for the purpose a 20ft. length of $^{7}/_{16}$ iron wire, but removed three strands of the wire in order to increase the resistance in circuit. This strand, then consisting of four wires, was heated up to a dull red in the sunlight, and naturally became considerably hotter when in the crevice in the tree. The strand was slowly drawn backwards and forwards through the tree in order to remove the soft charcoal formed, and also to admit air to complete combustion. The current used varied from 120 to 135 amperes, the voltage of the dynamo varying from 80 to 115. It took two hours and ten minutes to cut down the tree, which had the diameter above mentioned, and the operation was watched with great interest by a number of the inhabitants. It will be interesting to know how much quicker the work would have been done if the same voltage had been used to drive an electric motor geared on to a saw.

Portsmouth Telephones.—The sub-committee of the Portsmouth Corporation which is dealing with the telephone question, has received a report from Mr. A. R. Bennett that, if subscribers can only to be attracted in sufficient numbers, a municipal system could be established which would be efficient and remunerative at much cheaper rates than are charged by the National Telephone Company. Two schemes were proposed in the report—one for 1,200 lines to the exchange and one for 2,000. The cost for the smaller scheme, with 300 spare wires, would be £26,000, and Mr. Bennett estimates that the standing charges would be met when 500 subscribers had been obtained. A charge of £5. 17s. 6d. is suggested for an unrestricted service, or, as an alternative, £3. 10s. per annum with ½d. per call in addition. Another alternative would be £2. 10s. per year and 1d. per call. The Finance Committee, before recommending the town to undertake the work, desire to know how many people would become subscribers, and are asking to spend £150 on circulars and canvassing. Surely there can be no doubt that 500 subscribers could be obtained in a town like Portsmouth for connection with a telephone system with such low rates as mentioned above, and hence the cost of the canvass must be unnecessary.

Guard Wires.—The reporters of the accident which occurred at Vincennes on Monday have not, we are afraid, a clear knowledge to enable them to distinguish between telephone, telegraph, and tramway wires. The accident occurred through a balloon when ascending from Vincennes coming in contact with some overhead wires. A short-circuit ensued, which started an arc and ignited the fabric of the balloon. A large crowd was watching the balloon races, and immediately stampeded, owing to the fear that an explosion would take place. In the rush a considerable amount of damage was done, and women and children were injured. We are not told what happened to the aeronaut, who had the presence of mind to open the escape valve, but this did not prevent an explosion taking place, which set fire to the adjoining houses. We presume that if these balloon races are to be encouraged on this side of the Channel, we shall have the Board of Trade making rules to protect aeronauts from such catastrophes, and the cost of protecting them from trolley wires will have to be borne by the tramway authorities. From the description of the accident we almost fancy that in the case of Vincennes the electric light or trolley wire was cross-connected to the telephone wires. In any case, we are told that the telephones were not in working order the next day.

Guide-Books.—With the development of travel the red-backed guide-book is a sure indication by which strangers in a district can be detected. Apart from the advantages gained from railways, the extension of cyclist touring has also done much to open up new districts to the general public, and a whole series of cyclists' guide-books are now to be obtained for all civilised countries. A new type of guide-book has, however, recently been brought out in the States, which, it is stated by the *Electrical World*, will serve thousands where the cyclists' guide-books served hundreds. The new departure in question is a trolley guide-book, which covers New England and Washington. The idea is due to a lady, by name Katherine Abbott. Our contemporary adds that "according to Coleridge, the road the human being travels winds round the cornfield and the hill of vines, but according to Katherine Abbott, if you only stick to the route of the trolley car you can also see far more of the historic and romantic spots than were even contemplated in the philosophy of the old grand tour. This is not only true of Boston and of Washington, but of New York and Chicago, and will soon be true, we hope, of all the great cities of the Old World. There are plenty of guide-books, but those which are most needed for the future must follow the street car lines.

The Royal Insurance Company.—We have received from the above company a supplement to their rules for electrical installations in such cases where special safeguards have to be observed owing to particular surroundings. We must do the company the credit of saying that these rules appear to us to be reasonable in every case. Thus in breweries, distilleries, cold stores, and ice factories special stress is laid on keeping the wires free from joints and running the same on the true distribution system, by which all connections are made in distributing boxes. The company also advise the use of tell-tale earthed lamps on the switchboard, which will give a visible warning of leakages on either conductor as they occur. With drapery warehouses, etc., the risk of fire from faulty arc lamp resistance is provided against. We note that the company propose to put pressure on electrical engineers to conform to the rules of the associated fire offices by insisting on an extra charge if this is not done. We are not quite sure, however, that the associated fire offices are right when they insist on the absolute enclosure of all motors used in factories. In the circular sent to us it states that no ventilation is permitted into such mill or factory, but only

Digitized by Google

by pipe into the outside air. This means that the enclosed type of motor must be made considerably larger than it otherwise would be, and there are a number of cases where this precaution is not necessary, even in a textile factory, for which the rules are evidently meant. The air in the mill is not liable to spontaneous combustion or explosion, as it so often is in coal mines.

Electric Lighting Extensions.—There are certain areas in all our large towns in which building operations are proceeding rapidly, and in which the houses being erected are of such a class that their inhabitants are practically sure to be consumers of electrical energy. Central-station engineers working electric lighting undertakings in such areas are now able to obtain large increases of their load, if they only approach the builders of such houses in the right spirit. These builders, as a rule, are only too pleased to add any attraction to the houses which will make them sell more easily. Amongst these attractions is the statement that the houses are wired for electric lighting, and that the supply can be obtained immediately the purchaser takes possession. If this is done, it will be found that no gas-pipes will be put in, and hence the undertakers are sure of consumers in practically every house. This renders the laying of the mains a profitable outlay from the first, and also makes the calculation of the size of conductors easy, as the load can be predicted with almost mathematical accuracy. We know of certain blocks of buildings in the London district which are so wired, and are sure it will repay all central-station engineers to keep themselves well in touch with the building operations going on in their areas. It is absurd to allow at this date new houses of a good class to be erected and to be supplied with gas, because electric lighting mains are not laid near them. If gas is once used, the changing over to electric lighting is bound to be delayed on the score of cost and the vexed question of decorations being disturbed.

The International Electrical Congress.—The opening of the International Electrical Congress took place on Saturday, Aug. 18. Mr. Mougeot, French Under-Secretary of State for Post and Telegraphs, presided, and after a brilliant speech declared the congress open. The election of the president and vice-presidents was then proceeded with. Prof. Mascart had been elected president, and on his proposition Lord Kelvin was proclaimed hon. president. The vice-presidents were then elected as follows: Messrs. Moissan, H. Fontaine, and Gariel, of France; Messrs. Kohlrausch and Dorn, of Germany; Prof. Eric Gérard, of Belgium; Messrs. Carl Hering and Kennelly, of the United States; Sir W. Preece and Prof. J. Perry, of Great Britain; Prof. Jullig, of Austria; Mr. De Fodor, of Hungary; Prof. Colombo, of Italy; Mr. Chatelain, of Russia; and Dr. Turrettini, of Switzerland. Mr. M. P. Janet was nominated general secretary. Then followed the dividing up of the sections. The congress appointed the president of each section, and left it to him to appoint his own staff. The presidents of the sections are as follows: Section 1, dealing with scientific applications and measuring instruments, Prof. Violle; Section 2, Messrs. Hillairet and H. Fontaine (this section was divided into two sub-sections, one dealing with the production of electrical energy, its transformation, transmission and distribution, and electric traction, and the other dealing with electric lighting); Section 3, dealing with electro-chemistry, Prof. H. Moissan; Section 4, dealing with telegraphy, telephony, and their various applications, Mr. Wunschendorff; and Section 5, dealing with electro-physiology, Dr. d'Arsonval.

Rapid Communication.—We are now so used to telegraphic communication that any interruption in the same is looked upon as a personal hardship by every reader of a daily paper. In no instance has this interruption been more felt than in the campaign in China. All the time telegraphic communication was maintained between the sea coast and Pekin, European nations knew within a few hours the verdict of their representatives in that city as to the probability of the spread of the Boxer rising. Immediately this wire was interrupted, we were thrown back 50 years in our means of obtaining communication. Rumours of all kinds then became transmitted to Europe, and, as is always the case, the untrue news vastly exceeded in volume any items to which credence could be given. This state of affairs reminds us of what our forefathers had to submit to in times of war, when it took weeks instead of minutes for the news of victory or defeat to reach London. We trust that the uncertainty of the last few months in obtaining news from the representatives of Britain and of other nations in Pekin, will remind all concerned of the disastrous state of affairs which would result from a war with this country in which cable communication with our Colonies was interrupted. This reminder should be quite sufficient to lead to the establishment of all-British cables to our various Colonies and dependencies. In the laying of these cables great care should be taken that the routes should not be known to any outside the Government, so that the work of interrupting them would be rendered difficult. It would, of course, be rather difficult to keep the general lines absolutely secret, but it would be well worth a considerable extra expense to prevent the position of the cable being known within 100 miles, even if it became necessary to dispatch bogus cable ships or even to lay lengths of dummy cable.

The British Association.—The Bradford meeting of the British Association, although it does not open until Wednesday next, seems, from all appearances, to merit success. Thus the local committees have organised early, and from certain hints we gather that they have taken steps to avoid the great defects of the Dover meeting. It will be remembered that at Dover the accommodation was limited, and that speculative individuals secured this limited accommodation with the idea of making large profits out of the members attending the meeting. The natural outcome was that the members did not pay the price demanded, and the meeting suffered for lack of attendance. At Bradford the local committee have even organised the hotel accommodation, with, we trust, advantageous results. The reception rooms, which are situated at the grammar school, will be opened on Monday next from 2 p.m. to 6 p.m., and on the succeeding weekdays from 8 a.m. to 6 p.m. On Sunday, Sept. 9, the rooms will be open from 9 to 10.30 in the morning and 2 to 5 in the afternoon. Most of the clubs in Bradford will keep open house to the members of the association, while the Bradford, the Ilkley, and Ravenscliffe golf clubs will do likewise. The social functions of the meeting are the following: On Thursday, Sept. 6, a conversazione by the Mayor and Mayoress in the St. George's Hall, preceded by a reception by the local committee in the municipal technical college from 3.30 to 6 p.m. On Friday the local committee have organised a smoking concert. In the next week, on the Tuesday, the Mayor and Corporation give a soirée in St. George's Hall, and there will be a full-dress concert in the same place the next evening. The garden parties and excursions are too numerous to mention in our columns. A representative list of works in the district is given as being open for inspection, amongst which are the Corporation electricity works, where Mr. R. A. Chattock will be pleased to welcome visitors. The destructor works of the Corporation will also be open for inspection, under the supervision of Mr.

Digitized by Google

McTaggart, the engineer. We gave in our last issue a list of the papers to be read in Section B, from which it will be seen that the business side of the meeting is in good hands.

Electric Waves.—The following is an abstract of a paper read by Messrs. Blondlot and Gutton before the International Congress of Physics and Electricity at Paris this month. The subject of the paper is the rate of diffusion of electric waves. In the paper the authors give particulars of various experiments which they did to determine this rate. After the attempts of Hertz and Lecher, Mr. Blondlot has found the rate of diffusion. The length of the waves of a sounder is connected with its tune of vibration and with its velocity by the equation $\lambda = V T$. The length of the wave, λ, he determined experimentally by placing the sounder between two wires, along which he diffused the waves, and by measuring the width of the wave at the bottom. The period, T, he obtained from Lord Kelvin's equation, $T = 2\pi\sqrt{L C}$; the capacity is measured and the self-induction calculated. In continuation, Mr. Blondlot has measured the rate of diffusion of an electrical impulse of short duration by a method which is independent of theory. He measures the time taken for it to travel along a copper wire of great length. Experiments conducted on a different principle have been made in America, first by Messrs. Trowbridge and Diane, and then by Mr. Clarence Saunders. These scientists measured the length of the wave of electric oscillations which travelled along two parallel copper wires, and obtained the corresponding period by photographing the reflection of the spark in a revolving mirror. The equation $\lambda = V T$ gives the velocity. Finally, Mr. MacLean has measured the rate of diffusion of the waves in air. He measured the length of the waves given off by an exciter and reflected back by a metallic mirror, and then determined the period by photographing an oscillating spark. The figures given by these three different experiments agree very well, and are similar to the figures for measuring the velocity of light or the coefficient of transformation of the units.

Electro-Synthesis—The following is an abstract of a paper by Mr. O. Dony-Hénault which appeared in the *Zeitschrift fuer Elektrochemie*. The abstract appears in *Science Abstracts* for August, and reads as follows: "In the electro-synthesis of organic compounds two classes of reactions are to be distinguished—those in which the compound is formed by the inter-action of the ions, as in the formation of ethane by the electrolysis of acetic acid, and those in which the liberated ions act on a non-electrolyte in the vicinity of one of the electrodes, as in the reduction of nitrobenzene to aniline. This paper is the first of a series in which it is proposed to study reactions of the second class more systematically than has hitherto been done. Stress is laid on the importance of ascertaining the exact experimental conditions favourable to each synthesis, and the E.M.F. at the working electrode is considered to be of more value than the current density as a measure of the chemical action of the ions. Every organic compound capable of entering into reaction with the liberated ions acts as a depolariser, and the requisite condition for the decrease of potential is that the reaction shall take place with loss of free energy. Thus the electrolytic decomposition point for chlorine ions in normal hydrochloric acid is 1·31 volts (compared with hydrogen), whilst in the presence of phenol the required E.M.F. is reduced to 0·9 volt. Accordingly, as some preliminary experiments have already indicated, the quantitative conversion of phenol into one or more chlorine derivatives should be made possible by careful regulation of the E.M.F. Similar observations apply to the preparation of bromine derivatives of phenol. A series of experiments, described in detail in the paper, has been carried out on the electrolysis of dilute sulphuric acid in the presence of methyl and ethyl alcohols. The results show that by keeping the anode potential between 1·3 and 1·66 volts throughout the electrolysis a quantitative conversion of ethyl alcohol into aldehyde is effected; with higher potentials the yield of aldehyde diminishes, and acetic acid and ethyl hydrogen sulphate are formed. In the case of methyl alcohol the author confirms Renard's observation that formaldehyde is not produced, the primary oxidation product being probably methylal. The paper concludes with some remarks on the analogy between chemical and electrochemical modes of oxidation, and it is shown that the limited oxidation of alcohol to aldehyde can be effected chemically by means of cupric oxide or lead peroxide in alkaline solution."

Illumination.—Dr. Louis Bell still continues his series of articles on the elements of illumination in the *Electrical World*. In his eighth article he deals with the distribution of lights for interior illumination, and with the actual illumination in candle-power per square foot which it is necessary to obtain. The author gives formulæ for these principles, introducing the factor for the effect of diffused light from the ceiling or walls. He points out that the diffusion does not materially change with the position of the lamps in the room. In other words, a change in the position of the lamps makes but a small difference in the intensity of the illumination. In fact, in an ordinary room the moving of the lights from their usual height up to the ceiling does not seriously affect the illumination if the walls and ceiling are of good diffusing media. Of course, if the walls are dark, such a change makes a considerable difference. In this case Dr. Bell suggests that reflectors should be placed behind the lamps if they are placed near the ceiling. But the reflecting media must be placed so that they do not give the appearance of beams giving definite bright areas. In order to avoid this, ground or frosted bulbs should be used. The author concludes that about 1 c.p. for three square feet of floor surface should be provided, which is equivalent to providing one 16-c.p. lamp for about every 50 square feet. This is certainly quite sufficient, and from our actual experience we should say that it is more than is required in many cases. The author compares the standards adopted by other experts, such as Uppenborn, who advocates 1 c.p. per 3·6 square feet; Piazzoli, who advocates 1 c.p. per 3·5 square feet; and Fontane, who suggests 1 c.p. for every seven square feet. For ordinary domestic lighting Dr. Bell considers that a good plan is to give a diffused illumination of, say, 0·5 candle-foot for the whole of the room, together with a working illumination of from 1 to 1·5 candle-feet in addition for any parts requiring special lighting. The most important rule for domestic lighting is, in his opinion, never to use an incandescent or other brilliant light unshaded. Either ground or frosted bulbs should be used, or opal shades or holophane globes. Ornamental shades of coloured glass or fabrics are useful for harmonising with the surroundings, but, of course, they are rather wasteful of the light. In conclusion of the eighth article, Dr. Bell gives the number of lamps he would use in the various rooms of a house, and also the square feet area per candle-power in these rooms. These are as follows: the square feet per candle-power in the hall 4·7, in the library 3·1, in the reception-room 7, music-room 3, dining-room 2·7, billiard-room 2·3, bedrooms 7, dressing-rooms 4·7, servants' rooms 9·4, and in the bath-rooms 5,

SUNDERLAND TRAMWAYS.

The first section of the Sunderland tramways to be worked electrically was opened for traffic on the 15th inst., after having been tested by the Board of Trade and Local Government Board inspectors. As will be remembered, the whole of this tramway work has been placed in the hands of Mr. J. F. C. Snell, borough electrical engineer, who has had to design all the equipment and the overhead construction. It is worthy of note that the work of reconstruction has been very quickly proceeded with. In fact, the Corporation of Sunderland only received sanction to their Tramway Act last year, so that little over 12 months has elapsed since the sanction was given, and yet the first section of the tramways is now running electrically. The actual work of reconstruction was only commenced on Nov. 1 last year. The line now open consists of the Christchurch and Roker road, which is a total route of four miles and one furlong of single track. Twelve miles of track are, however, being constructed for electrical working, while under the Act the Corporation are empowered to provide 23 miles of track.

The gauge adopted in Sunderland is 4ft. 8½in., which allows of very easy running. The lines in question were previously equipped for horse traction, and it was stipulated in the contract for reconstructing the track that the work must be carried out without interfering in any way with the tramway service. The new rails, which are of considerably heavier section than the previous ones, weigh 96lb. per yard. They are of the girder type, 7in. in depth, and were supplied by the contractor in 30ft. lengths. The fishplates weigh 64lb. per pair, and a sole-plate is laid under each joint, securely bolted to the under flange of the rails. This tends to prevent the rails sinking into the concrete at the joint owing to a slight yield in the fishplates. These rails are laid on a 6in. bed of concrete. Some very good special work has been done at the crossings by the contractors. The space between the rails is in some places filled in with creosoted wood blocks, while in other places Aberdeen and Norwegian granite setts are used to make up the roadway. The contractors for the reconstruction of the track were Messrs. Dick, Kerr, and Co.

The overhead equipment was supplied under and directed by the British Thomson-Houston Company. Fig. 1 shows the meeting of two tramcars on a section of the road equipped on the central pole construction. Fig. 2 is a view taken at a point at which the central pole construction merges into a span-wire construction, while Fig. 3 is a typical example of the side-pole type of overhead work. At the base of the column in Fig. 3 will be seen a section switch pillar. These are placed at every half-mile along the route, so that the trolley wires are split up into half-mile sections for convenience in isolating faults. Care has been taken throughout to give a flexible suspension to the trolley wires, which has the additional advantage of giving double insulation. The diameter of the trolley wire used at Sunderland is ·325in., and it is supported at an average height of 21ft. from the ground. The whole of the overhead accessories and materials are made of gunmetal, except, of course, where insulation is required. The feeders supplying the tramways were supplied by the Callender's Cable and Construction Company, Limited, and are drawn into Sykes's earthenware conduits, which were laid along the roads in the clear while the tracks were being reconstructed. There are four feeders provided for the present contract of 12 miles of track. One of these commences with ¼in. in section, and divides up into two ends, each ·122 to a square inch. The other feeders are ·2 of a square inch in sectional area, reducing at their ends to ·122 square inch. Great care has been taken by Mr. Snell in the design of the return circuit for the current; thus the whole of the rails are carefully bonded together and the tracks are bonded opposite every pole. There are clear way bonds also placed half-way between each pair of poles. Besides the conductivity thus given in the track for the return current, Mr. Snell has also provided two negative feeders, which are connected to different parts of the system and go back to negative boosters in the station. These negative boosters are capable of dealing with a current of 250 amperes, and can give a voltage of 30 volts. The excitation in the usual way is provided by the feeder current going through a series cell; but a second method of excitation by means of a shunt coil is provided, so that the boosters can be worked even if the feeder connected to the series turns is not

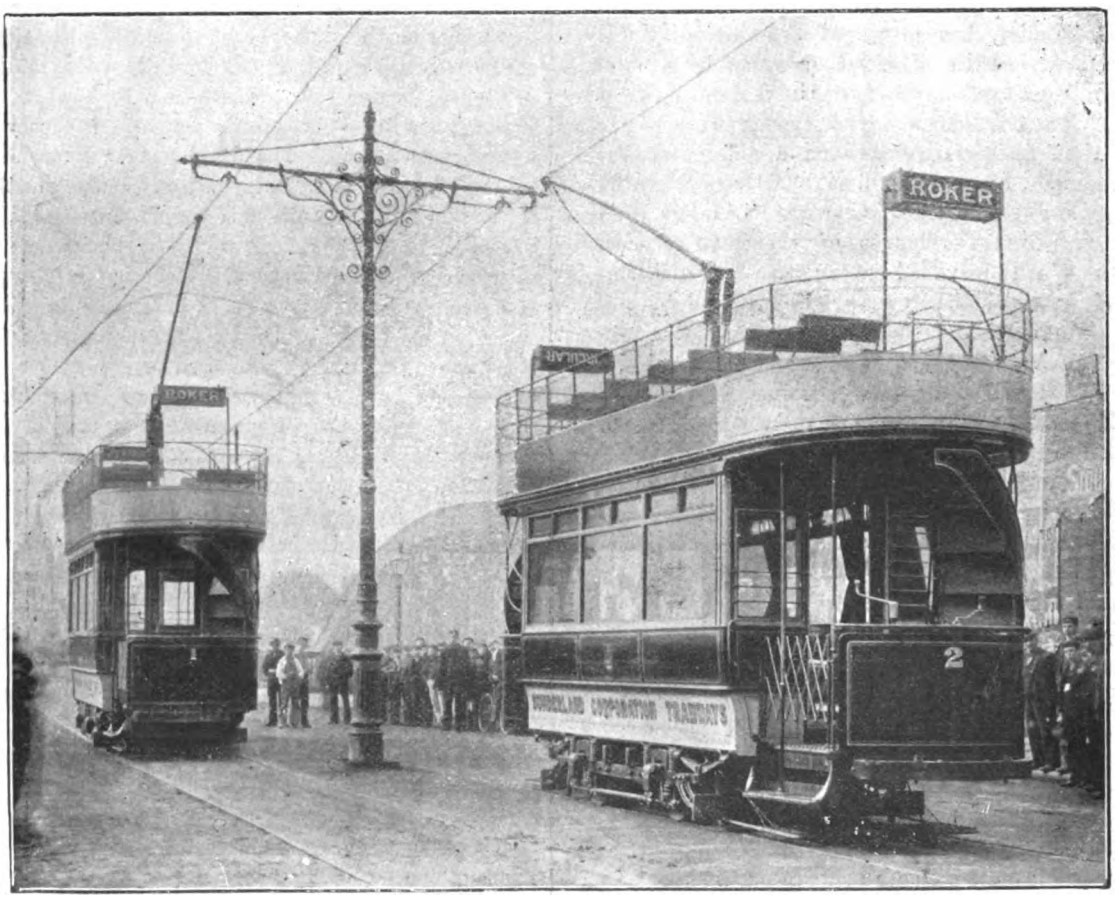

FIG. 1.—The Sunderland Electric Tramways.

Digitized by Google

being used. We understand that Mr. Snell has based his calculations on a drop of voltage between any two points on the return circuit of 3½ volts—*i.e.*, one-half that allowed by the Board of Trade as a maximum. This will provide margin for contingencies, such as loose bonds, etc. These negative boosters have not yet been put to work.

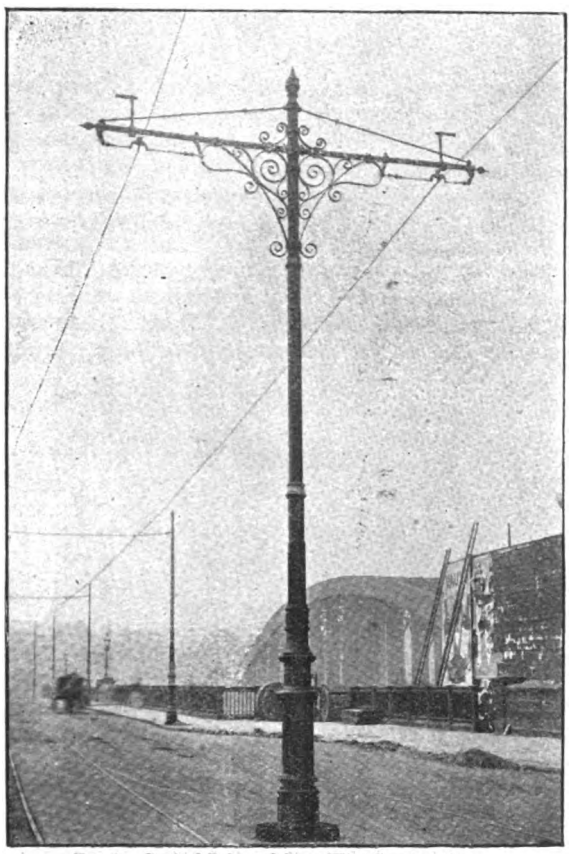

FIG 2.—Central Pole and Span-Wire Construction.

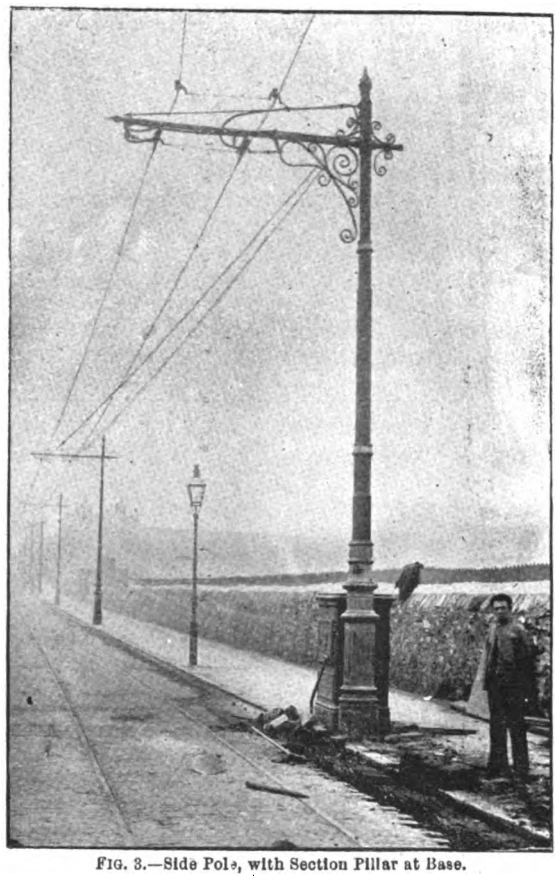

FIG. 3.—Side Pole, with Section Pillar at Base.

The first instalment of cars consists of 12 double-deck single-truck cars, of the type which is shown in our illustration (Fig. 1). These are equipped with Walker motors and controllers, and have three distinct brakes—*i.e.*, a standard air-brake, an electric emergency brake, and a hand-brake. These cars are able to seat 56 persons, of which 22 are carried inside and 34 outside. The staircases at either end of the car are made with the reverse spiral to that which is usual, which gives much greater safety to passengers ascending them. It will be seen from the illustration that there is no break in the guard rail running round the upper deck of the car, as is too often the case with the older types. Besides these, there are to be supplied six double-bogie cars, which are to be mounted on maximum traction cars, and are capable of carrying 70 passengers. Besides there are to be used eight single-deck cars, only seating 30 passengers, which will be employed on the Tatham-street route, where a bridge prevents the use of a double-deck car. In fact, the height available is only 13ft. 6in., and the road cannot be lowered. At present the principal car-shed is at the Wheatsheaf, where 50 cars will be able to be accommodated. The designs, however, are for a new shed and repairing shops on the south side of the river, which will hold 60 cars. These new sheds will be on the Hilton-road route.

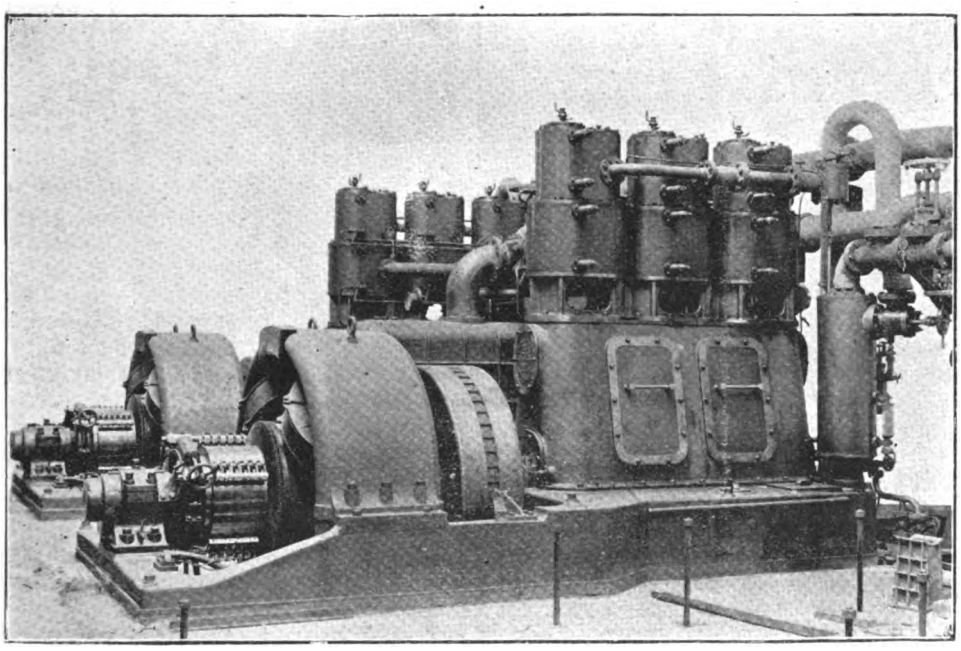

FIG. 4.—View of Two of the Traction Generating Sets.

The energy for these tramways is taken from the Dunning-street lighting station of the Corporation, where three steam generators of 450 h.p. are being installed for

Digitized by Google

tramway work. Fig. 4 is a view of two of three generating sets, which consist of Bellis's three-crank compound engines direct coupled to four-pole dynamos, made by the Sunderland Forge Company. The switchboard (Fig. 5) was manufactured and supplied by Messrs. Moon, Lochlin, and Co. The engines take their steam from Galloway boilers, which are also used for lighting, and which will be seen in Fig. 6. Messrs. E. Green and Son's economisers are used in the flue from these boilers. The exhaust steam from the engines passes into Wheeler surface condensers, an independent condenser being provided for each pair of engines. In connection with the condenser is used a Barnard cooling tower, in which an up draught is maintained by means of an electric fan, supplied by the Sunderland Forge Company. In order to provide for emergency loads, induced-draught fans are provided in the main flues. This induced-draught apparatus delivers its exhaust into an auxiliary steel chimney. This apparatus was supplied by Messrs. Dutilh Smith, McMillan, and Co. In the near future mechanical stokers and a coal-conveying plant are to be added. We understand that the load on the station for light is increasing so rapidly that a new power-house is shortly to be erected in the town, from which both light and power can be supplied.

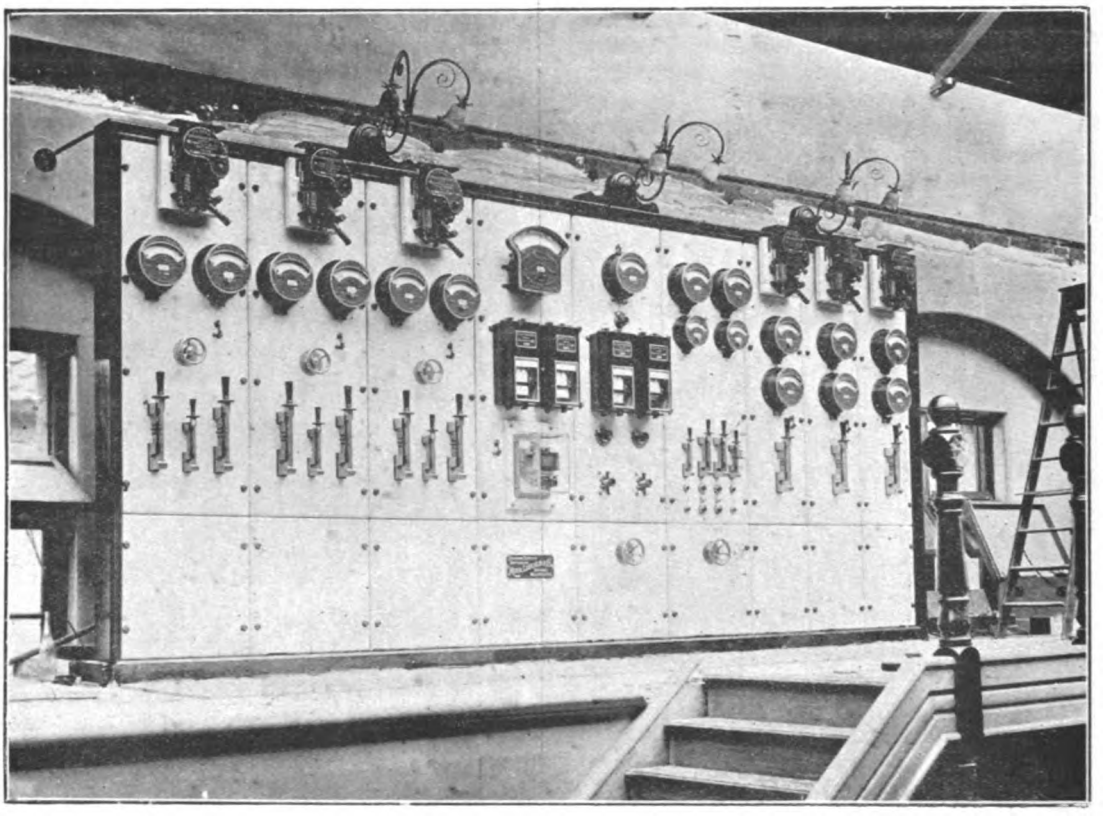

FIG. 5.—The Sunderland Traction Switchboard.

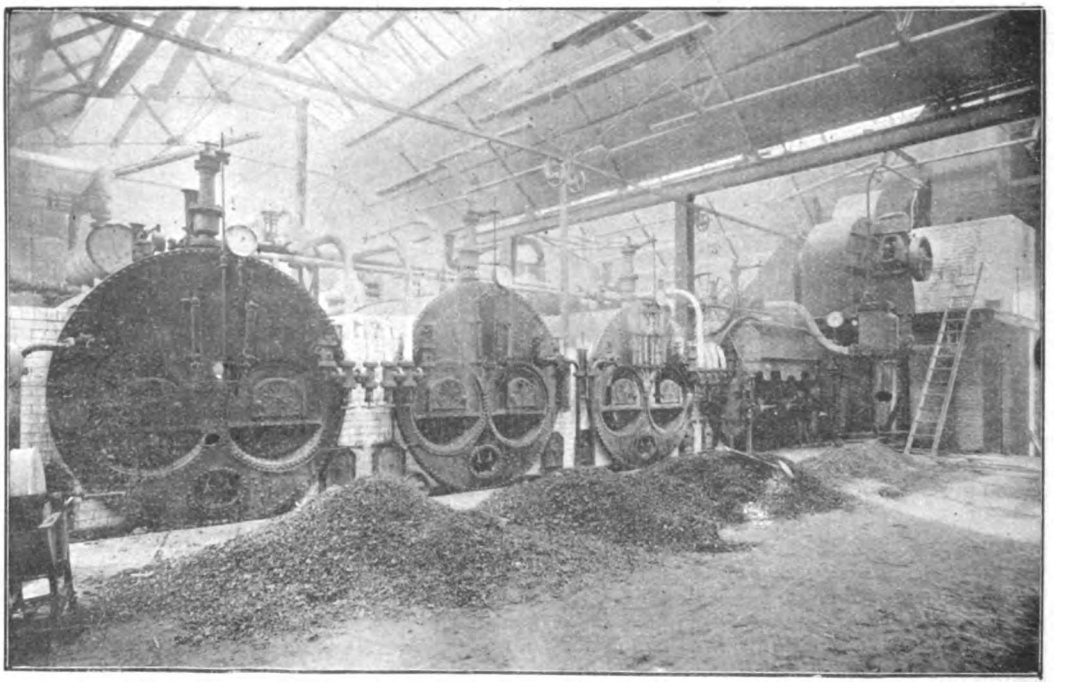

FIG. 6.—View in the Boiler-House.

On the occasion of the opening ceremony on the 15th inst. a lunch was given in the town hall by Mr. Councillor Trewhitt, chairman of the Tramway Committee. After the lunch "The Success of the Tramways" was proposed by Mr. Hopkins, C.E., and was responded to by Mr. Trewhitt, who gave a history of the undertaking and how it was taken up by the Corporation. The usual visits had been paid to other towns, including some on the Continent.

Digitized by Google

The specifications had all been prepared by their own borough electrical engineer, Mr. Snell, together with their borough surveyor.

After lunch and speechmaking was over, a number of ladies joined the party, which boarded the cars drawn up opposite the town hall. An opening run was then made to Christ Church, after which a complete journey to Roker was made. Sunderland, as is perhaps well known, lies on both banks of the Wear, and comprises large shipbuilding yards, docks, and coal staithes. Roker is a pleasant seaside suburb of Sunderland, north of the river, and a favourite resort of the townspeople in the summer time. This has caused the section of the tramways which joins Roker to Sunderland to be first equipped with electric traction.

After examining the electric tramways at Sunderland one of the things that strikes us most is that there are so many kinds of overhead equipments. Thus, Fawcett-street, which is the finest street, has been equipped for the most part with rosettes and span wires, but it seems a pity that rosettes could not have been used in the case of the whole of Fawcett-street, but it is understood that the quality of the property would not allow of this. In other streets two single poles carrying a span wire are used, notably on the bridge crossing the Wear. In others a short bracket pole is used, one on each side of the street, in others a long bracket pole on one side of the street,

MR. J. F. C. SNELL, BOROUGH ELECTRICAL ENGINEER, SUNDERLAND.

while in others centre poles are used. Evidently the Sunderland Corporation do not mind having a considerable number of poles in the streets, as besides the poles for the overhead equipment, there are the poles for the electric lighting, as the lighting is not done from the tramway poles.

The permanent-way work and the overhead equipment, which was all done by Messrs. Dick, Kerr, and Co., strikes one as having been done in an exceptionally sound and substantial manner, and owing to the fact that there are few curves, the overhead work cannot be said to offend the eye of even the most fastidious person, and strikes one as considerably neater than that which one has seen in some other towns. We should certainly advise corporations to visit Sunderland, and see how little obstruction is caused by this system when well carried out.

The work must have been carried out very expeditiously by the contractors, whose resident engineer was Mr. Hay, who we did not notice as being present at the opening. We understand that the overtime and all-night work which this class of work often necessitates had made it necessary for him to take a holiday, which the completion of the work enabled him to do.

We understand that the chairman (Mr. Trewhitt) is very largely responsible for inducing the Corporation to go in for electric traction, and he is to be congratulated on having engineered the scheme through the Council in the successful manner he has done. Similar congratulations are due to Mr. Snell for such of the first portion of the extensive scheme of electric traction he has designed. The photographs from which our illustrations were prepared were taken by Mr. J. W. French.

TAUNTON ELECTRICITY WORKS.

The official inauguration of the extensions to the electric lighting plant at Taunton and the remodelling of the station was referred to in our recent issue. The present time seems to us to be a suitable one at which to review briefly the history of the electric lighting undertaking at Taunton. At the same time particulars of the economies which have been effected by discarding the old plant and laying down new will be of interest to all, and particularly to those unfortunate central-station engineers who are expected to make good returns with obsolete plant.

Taunton claims to be the first town in England to establish street-lighting by electricity on a permanent basis. It was in 1886 that Mr. H. G. Massingham introduced the electric light for his own and adjoining premises in Taunton. This led to a desire on the part of the townsmen to have a general system of lighting, and after considerable opposition and a three months' trial of arc lighting in the parade the Town Council granted Mr. Massingham's company a contract for street-lighting. The

THE MAYOR OF TAUNTON.

arc lighting in this instance was carried out on the Thomson-Houston system by means of series lamps supplied by open-coil arc lighters with spherical armatures. At the same time an alternating-current plant was laid down which gave a supply for incandescent lighting for private houses and shops by means of transformers placed in the consumers' houses. Of course, the capital obtained by this company was not large. On the other hand, the price of electrical machinery was high, and the efficiency of the same was exceedingly low when compared with the result which can be obtained at the present time. The final result was that, while the company was able to pay a dividend for a few years, it could not meet its depreciation charges, nor obtain the additional capital required to improve the plant and extend the system of lighting. Thus, after the public lighting had been done by the company for about seven years, it was ultimately arranged that the Corporation should buy the whole of the undertaking. We believe that there must be some Irish blood amongst the leading inhabitants of the town, which would account for the strenuous opposition which the proposal to purchase called forth. Reports and counter reports, rival experts, and endless newspaper war, ended in the Corporation gaining the day. The electric lighting undertaking as a municipal work was then handed over to a committee, of which Alderman Potter was chairman, and he has had this honour and the heavy responsibilities of the post ever since. Before proceeding to the works as now arranged, a

Digitized by Google

few notes on the old equipment will be of interest. Thus Fig. 1 shows a general view of the old plant in the engine-room, from which it will be seen that slow-speed horizontal steam-engines were used to drive a countershaft which occupied the whole of the middle of the engine-room, while from this countershaft were driven the various arc lighters, etc.

In Fig. 2 we show a group of four of these Thomson-Houston arc lighters, while Fig. 3 is an illustration of the complicated system of belts and guards which was employed. In the background of this last view a certain amount of the new plant can be seen. As an example of the variety of the plant in the station for the conversion, we may mention that in 1896 the Corporation had one 50-h.p. Bumsted and Chandler engine which ran at 380 revolutions. The two horizontal engines seen in the illustrations were of 75 h.p. each and ran at 128 revolutions. These were of the Ruston and Proctor make. Besides these there was a Belliss engine of 180 b.p. and two Willans engines of 135 h.p. The Willans engines were, we believe, used for belt driving. The collection of alternators of the Thomson-Houston make included one of 30 kw., two of 70 kw., and one of 90 kw. These worked at a voltage of 2,000, and at that date were mostly employed in supplying transformers in consumers' houses, although at that time a few lengths of low-tension distributors had been laid. The arc lighters were designed to give 1,500 volts. As in the boiler-house a similar diversity of plant was to be found, it is not to be wondered at that the cost of coal per unit sold was considerable.

ALDERMAN W. POTTER, CHAIRMAN OF THE TAUNTON ELECTRIC LIGHTING COMMITTEE

MR. E. B THORNHILL, BOROUGH ELECTRICAL ENGINEER.

It was in the early part of 1898 that Alderman Potter and his committee advocated that this station should be remodelled. It was then decided to call in an expert adviser, and Mr. E. Manville, of the firm of Kincaid, Waller, and Manville, was commissioned to prepare plans and specifications for the entire reorganisation of the work. Mr. W. H. Couzens, who for some years was the borough engineer at Taunton, and now is with the above firm, has had charge of the work for Mr. Manville, and his knowledge of the local situation has done much to enable the changes to be made without interfering with the continuity of the supply.

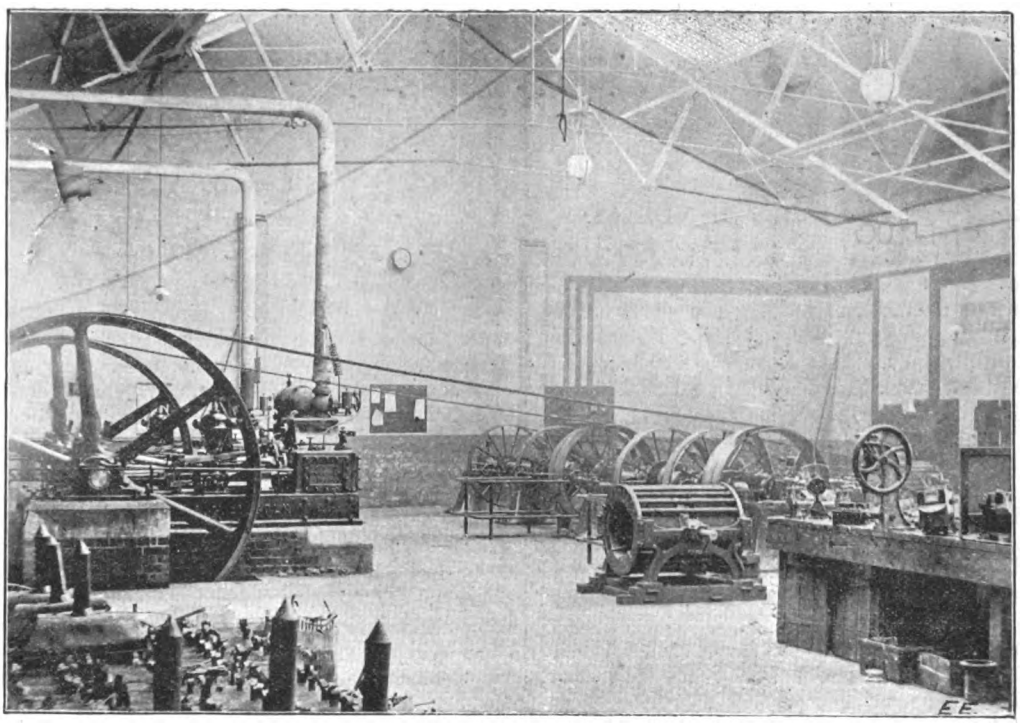

FIG. 1.—Taunton Electric Light Station as equipped with the Old Plant.

(To be continued.)

THE ELECTRICAL ENGINEERS' CONFERENCE IN PARIS.

[BY OUR SPECIAL CORRESPONDENT.]

THE VISIT TO MOLINEAUX.

On Friday afternoon the members of the two institutions assembled at the Gare St. Lazare, where they were received by M. Clérault, chief engineer of the Compagnie de l'Ouest, and M. Mazen, engineer, who conducted them over the various installations. A special train conveyed the members to Molineaux, and before visiting the electrical generating works, M. Mazen described the leading features of the scheme which is being carried out by the Compagnie de l'Ouest for equipping the line on the left bank of the Seine from the Gare St. Lazare to Versailles with electrical traction. There are certain difficulties in working this line, which has a length of a little more than 11 miles, owing to the fact that on a long section, where the new line has to cross the heights between Meudon and Viroflay, the gradients are as much as 10 per cent. It was found that the only economical way of working this line was by running electric trains with a third rail. The construction of the tunnel at Meudon, which has a length of more than 1·9 miles, presents some difficulty in consequence of the presence of loose sand, but these drawbacks are being successfully overcome, and the line will shortly be completed. The Molineaux installation has been carried out by the Compagnie Générale de Traction, and the electrical plant supplied by the Westinghouse Company. It generates triphase current at 5,000 volts, which is transformed at the Champ de Mars, Meudon, and Viroflay sub-stations into continuous current at 550 volts.

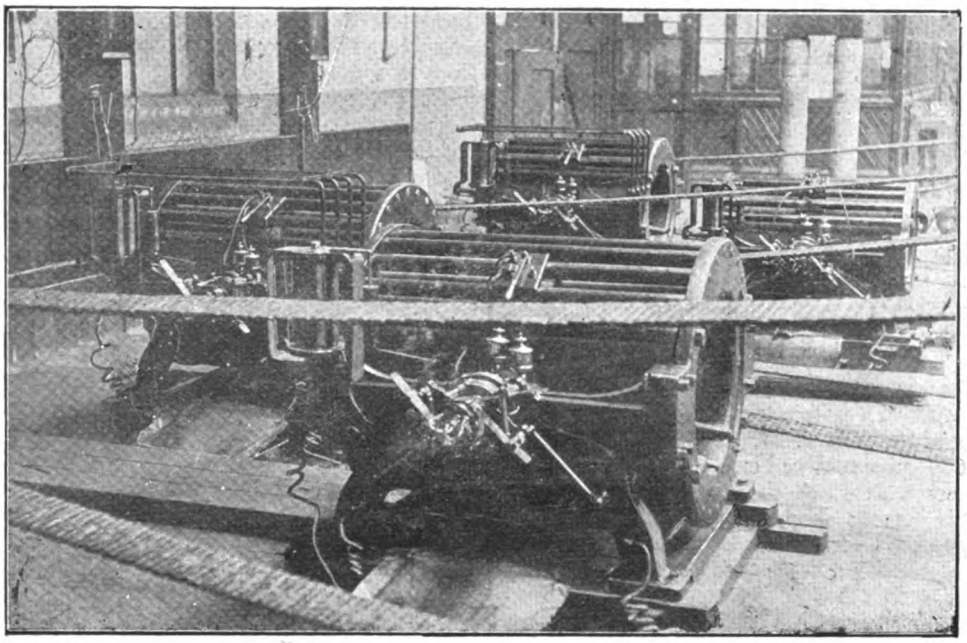

FIG. 2.—Group of Thomson-Houston Arc Lighters as previously used at Taunton.

The current is not only employed for traction purposes, but is used for operating the lifting gear and other mechanism in the stations, and for working a large number of pumps, machine tools, travelling cranes, etc. Electrical traction is at the present confined to the section between the Champ de Mars and the Gare des Invalides, where it is largely used by visitors in going from one part of the Exhibition to another.

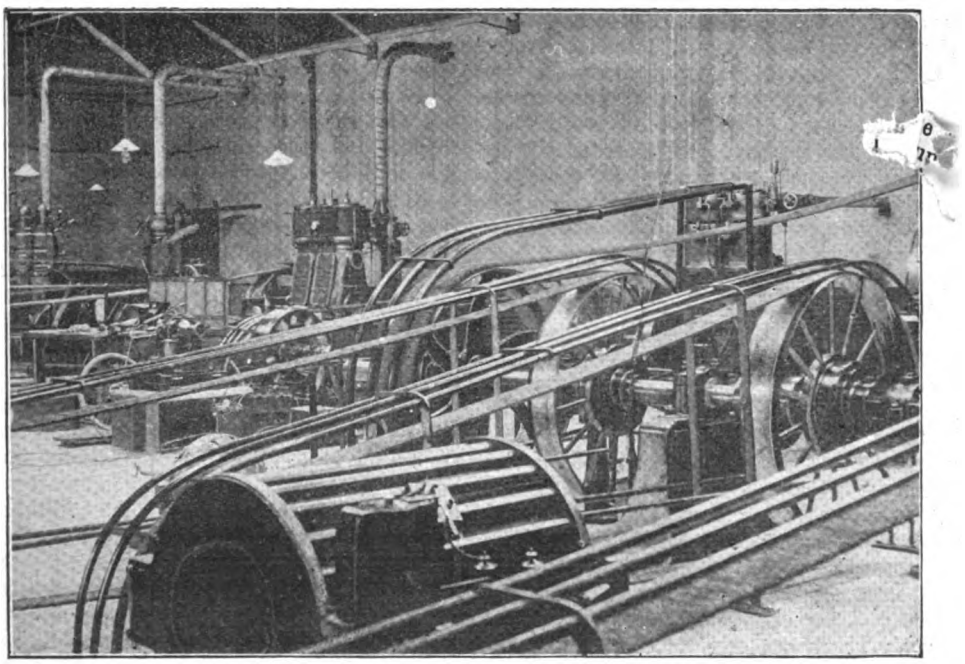

FIG 3.—View of the Arc Lighters, showing the Countershaft, Belts, and Guards, at Taunton.

The members were then conducted to the generating station, which will eventually contain nine dynamos, of which six will be driven by four-cylinder triple-expansion horizontal steam-engines, while the three others, which are already at work, are operated by horizontal compound engines. These two systems are being adopted with a

Digitized by Google

view of instituting a comparison between them. The building has a length of 365ft., and when the installation is completed it will be the largest in France. Current for the section of the line already working, as well as for operating the machinery in the stations and in the workshops, is generated by three dynamos of the flywheel type, driven by two compound engines constructed by Dujardin et Cie., of Lille. The rest of the building, where the other machines are being laid down, is boarded off, but judging from the progress being made it seems as if the whole installation will be completed before long. The dynamos have an output of 800 kw., and for short periods will run up to 1,000 kw. In this building are two travelling cranes, each able to lift 25 tons. Behind the engine-room is the boiler-house, which will eventually contain 27 semi-tubular boilers, constructed by Meunier et Cie, of Fives-Lille. Nine of these boilers are at work, and the rest are under construction, to supply steam to the engines now being laid down.

From here the members were conducted to the pumping station, where there are three centrifugal pumps, each driven by an electric motor of about 40 h.p. These pumps draw the water from the Seine into a basin and elevate it to a reservoir, where the water is always maintained at the same level, so as to secure a constant feed for the condensers. When the tank is full, the water in the basin has attained a certain level which automatically stops the working of the pumps. Each of these pumps has a capacity of 31,600 cubic feet an hour.

The thoroughness with which the installation is carried out is seen in the testing shop, which is equipped with every possible apparatus for testing the condition of the high and low pressure mains, the running of the alternators and steam-engines, as well as the working of the boilers and the electro-mechanical plants at all the installations now completed and about to be laid down by the Compagnie de l'Ouest. Arrangements are also made for testing every kind of apparatus supplied by manufacturers before they are accepted by the company. These comprise pressure indicators, tachometers, manometers, and all necessary apparatus for testing the condition of the steam and compressed-air plants, voltmeters, ammeters, wattmeters, galvanometers, etc., photometric instruments, and the necessary apparatus for testing the insulation of alternating current cables for voltages up to 50,000 volts, as well as for monophase, two-phase, and three phase currents from 5,000 volts to 2 volts, and continuous current from 10,000 volts down to the lowest pressure. In an adjoining room there is a feeder board, where the current is brought from the alternators by one cable of 5,000 volts, and split up to supply the feeders. Each feeder has its separate meter, and a duplicate meter is provided in case of accident. The high-tension main is composed of cables in which the three conductors are insulated with paper. The section of the cable varies from 25mm. to 150mm., and it is laid along the side of the railway in sand and covered by earthenware slabs and metallic wire. Each cable branches off into two cables at the sub-station, so that in case of leakage or other defect in one, the other can be used without interfering with the service.

On leaving the installation the members were conveyed by a special train to the Champ de Mars sub-station. This installation is composed of two separate parts—one for lighting the Champ de Mars station and working the various machines, turntables, lifting gear, and the like, and the other for supplying the energy required for traction. In each sub-station there is a special plant for transforming the triphase current into continuous current at 125 volts for lighting purposes and for operating cranes, turntables, and other machinery. There are two or three groups of transformers in each sub-station, and each group comprises a static transformer for reducing the tension from 5,000 volts to 100 or 200 volts, and a motor operating a generator for producing continuous current at 125 volts. The three sub-stations for transforming the current for traction purposes are situated at the Champ de Mars, Meudon, and Viroflay. Each has a transformer reducing the triphase current from 5,000 volts to 340 volts, and a rotary converter receiving the triphase current at 340 volts and transforming it into continuous current at 550 volts. These converters are got up to speed by means of a small machine producing continuous current at 550 volts.

The visitors now utilised the electric railway for reaching the Gare des Invalides. The trains at present running are nothing more than tramcars, but they will be replaced by larger vehicles when the whole line is in working order. In the stations the conducting rail is protected by boards which are inclined inwards on either side, so that the edges project slightly above the level of the rail, leaving just enough room for the contact-piece to pass between them. The rail is insulated by wooden blocks steeped in paraffin. The wood is boiled or rather left in a bath of paraffin at a very high temperature for about 24 hours, and it appears that this preparation results in an entirely satisfactory insulating material. On arriving at the Gare des Invalides the members proceeded to the machine shop, which is a particularly interesting building, and M. Mazen explained that it might be regarded as the cradle of electric traction in France, as it contains the first electric locomotive to convey passengers in that country. It is simply an ordinary locomotive frame upon which has been placed four Heilmann motors. These motors, constructed by Brown, Boveri, and Co., drive direct, and in order to give the required elasticity the motor carries at each end a metallic plate with pin projections at right angles to the plate, so that each pin is between the ends of two spiral springs fastened between the spokes of the wheels. There are four pairs of springs on each wheel, and, as may be understood, their purpose is to gradually overcome the inertia in starting. The motor is of the four-pole type, and is entirely enclosed. Ten electric locomotives of 800 h.p. are now under construction. In four of them the motors are geared with spur-wheel gearing, and in the others they are mounted direct on the axle. Another interesting thing in the machine shop is an electric crane, which is operated by a cable hanging down from the centre and carrying a small hand switch, which gives six separate movements to the crane and the winding gear.

The Compagnie de l'Ouest has not confined its attention solely to electric traction, as is seen in the adjoining compressed-air machine shop, which contains the first locomotive on this system used by the company. Three other locomotives are now being built. The idea in using compressed-air locomotives is partly to be able to rely on this form of power in the almost improbable event of the electric current failing, but more especially for shunting purposes and for running in conjunction with electric trains at moments when the traffic is particularly heavy. The frame is much the same as in the ordinary locomotive, but the suppression of the chimney and the steam-dome, as well as the rounding of the ends, naturally give it an entirely different appearance. The reservoirs have a capacity of one ton of air, and this will allow of the locomotive drawing 200 tons for a distance of 12½ miles.

From here the members went to the compressed-air station, which contains two groups of air-compressors operated by three electric motors of from 250 h.p. to 300 h.p., and supplied directly by triphase current at 5,000 volts. The compressors are on the Mékarski system, constructed by Brulé et Cie., of Paris. The air arrives from the main at a pressure of 13lb. per square centimetre into the first compressor, where it is compressed to 44lb., and after being further compressed in the second machine is delivered from the third compressor into a battery of accumulators at 176lb. Adjoining this building are the Belleville generators for supplying steam to raise the temperature of the air in the locomotives and for warming the station and other purposes.

The visit now having come to an end, Mr. GRAY, on behalf of the Institution of Electrical Engineers, thanked M. Mazen, M. Clérault, and the other engineers of the Compagnie de l'Ouest, who had displayed so much courtesy in showing them round these installations, and he was followed by M. MAILLOUX, on behalf of the American Institute, who felicitated the Compagnie de l'Ouest on the enterprising spirit they had manifested in carrying out these installations, and said it gave a denial to the reproach Americans were in the habit of making that European countries were behindhand.

M. CLERAULT briefly responded, and said that all nations

Digitized by Google

were closely united when it came to a question of industrial progress.

In terminating this report, it is only just to record the services rendered by Mr. Maurice Coster, manager of the Westinghouse Company's works, who assisted M. Mazen in explaining the different installations visited, and by Mr. W. G. McMillan, secretary of the Institution of Electrical Engineers, who was indefatigable in his efforts to make the meeting a successful one.

[In his first instalment of "The Electrical Engineers' Conference in Paris," our special correspondent, in speaking of the visit to the Exhibition, inadvertently mentioned that the Galloway engine shown was coupled to a dynamo by Siemens Bros. and Co. As a matter of fact, Messrs. Mather and Platt, of Manchester, and not Messrs. Siemens Bros., were the makers of the dynamo in question.—ED. *E. E.*]

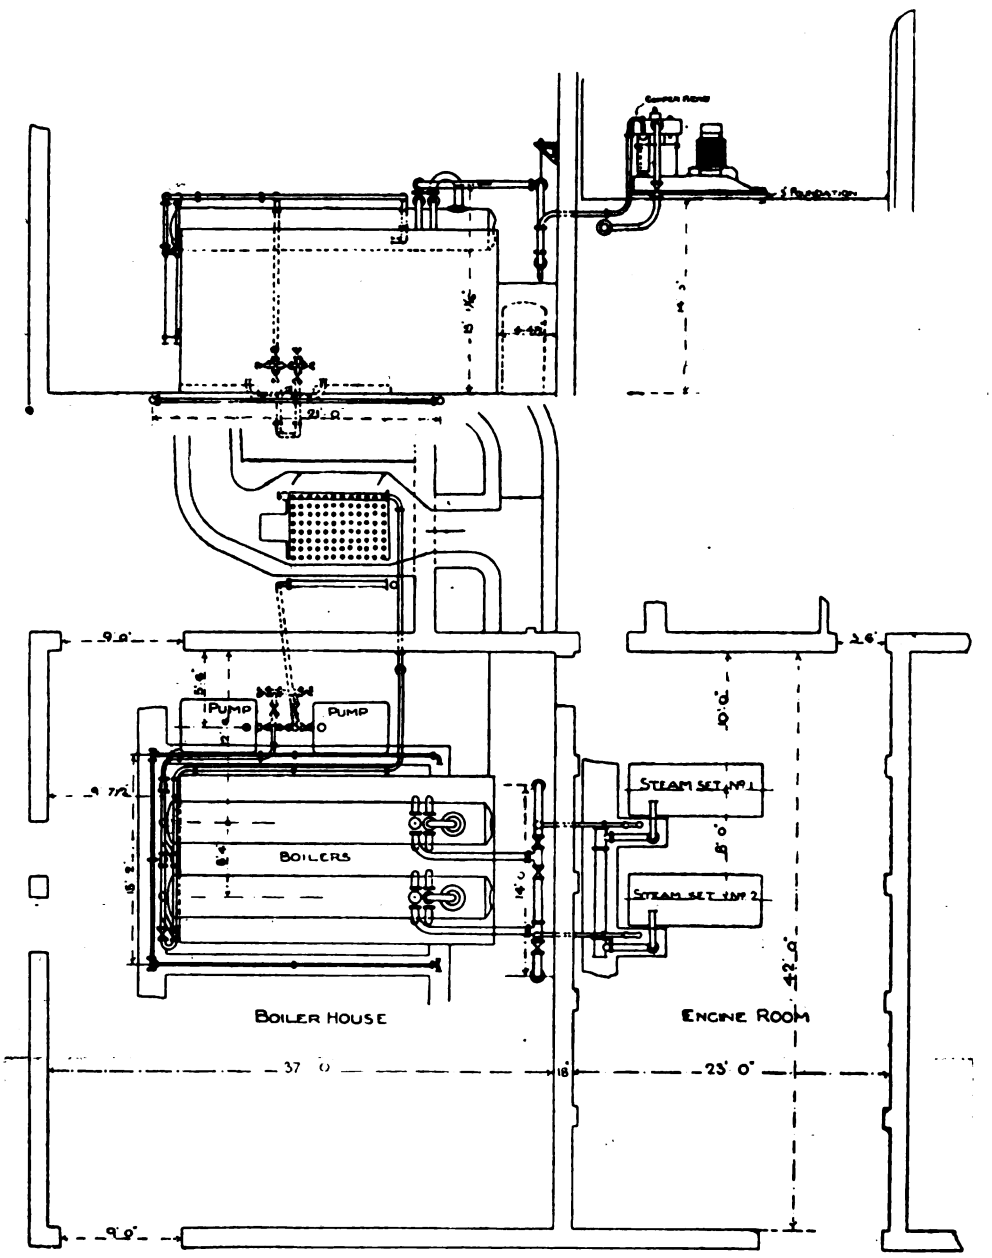

FIG. 1.—Ground Plan of Edmundson's Guernsey Station.

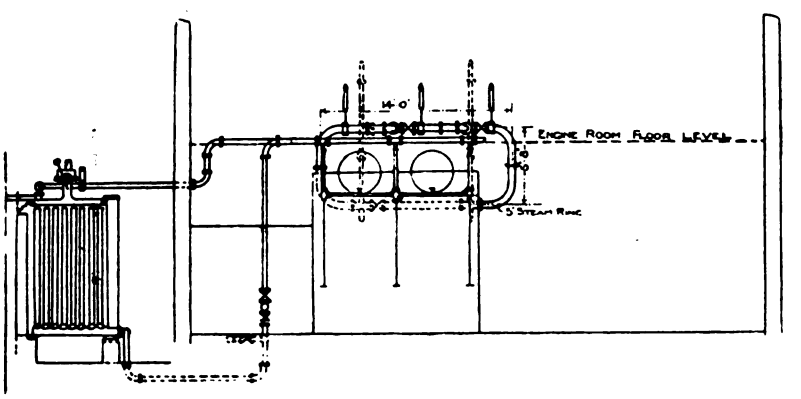

FIG. 2.—Details of Steam Ring, Guernsey Station.

EDMUNDSON'S ELECTRICITY CORPORATION'S WORKS AT GUERNSEY.

In our issue of Aug. 3 we gave a short description of the above works without illustrations. By the courtesy of Messrs. Edmundson's Electricity Corporation, Limited, we are now enabled to give a few reproductions of photo-

Digitized by Google

graphs taken at the works, besides a diagram of the switchboard connections, and a ground plan of the station, showing the positions occupied by the several items of plant installed. It will be remembered that this plant consists of two Babcock and Wilcox 100-h.p. water-tube boilers, fitted with superheaters; one Worthington feed pump, capable of delivering 10,000lb. of water per hour to the boilers; one Hayward Tyler three-throw electrically-driven pump, capable of delivering 13,000lb. of water per hour; two E.C. 5 Belliss 100-b.h.p. engines, running at 500 revolutions per minute, with a steam pressure of 130lb.; two 74-kw. Parker dynamos, yielding 160 amperes at 410 to 460 volts each; one Green's economiser with 96 tubes; 230 D.P. accumulators with a rated capacity of 715 ampere-hours; one balancer-booster set, the balancers being able to supply 50 amperes at a terminal pressure of from 210 to 230 volts, while the booster gives 80 amperes at 70 volts terminal pressure. The steam-piping is arranged on the ring system, the pipes being of wrought steel with welded seams and heavy forged flanges screwed on hot and brazed. The feed pipes are arranged in duplicate to allow of either pump supplying either boiler. Both the exposed parts of the boilers and steam-pipes are covered with magnesia lagging. The switchboard is of Messrs. Edmundson's standard type in marble, and is arranged for four dynamos and four feeders. The feeders are triple-

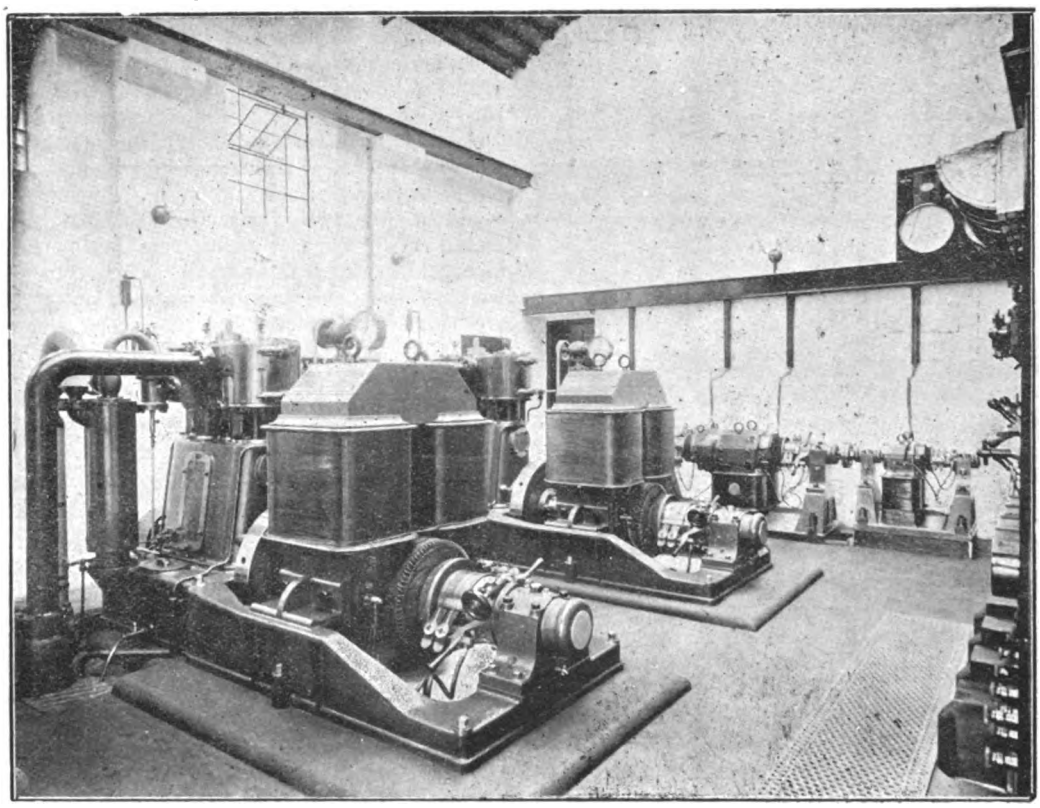

FIG. 3.—Interior View of Engine-Room, Edmundson's Guernsey Station.

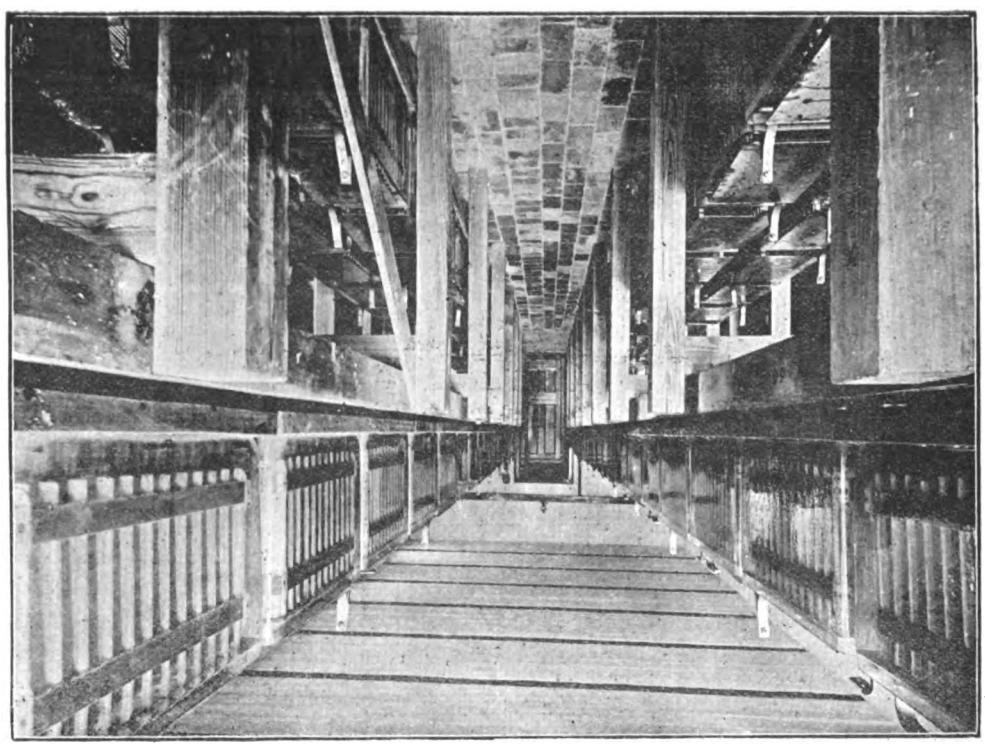

FIG. 4.—Interior of Accumulator-Room, Edmundson's Guernsey Station.

Digitized by Google

concentric, and the distributors of the three-core type, all being lead-covered and armoured.

The following additional plant is now on order: one Babcock and Wilcox boiler, fitted with superheater, and

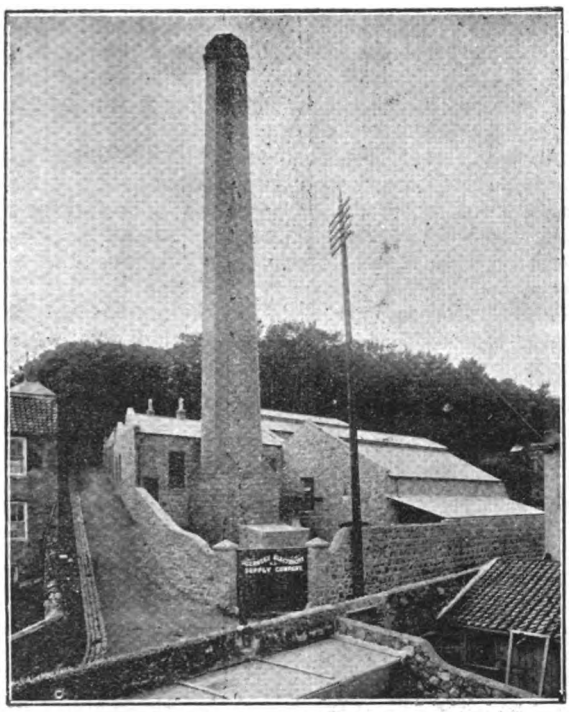

FIG. 5.—Exterior View of Edmundson's Guernsey Station.

possessing 2,437 square feet of heating surface; one T.E.T. 3 Belliss three-crank triple-expansion engine, to develop 270 b.h.p. at 420 revolutions per minute; and one Parker dynamo to yield 420 amperes at from 420 to 460 volts terminal potential. For further particulars of the station we must refer the reader back to our issue of Aug. 3.

MESSRS. DAVEY, PAXMAN, AND COMPANY'S STANDARD IRONWORKS, COLCHESTER.

(Concluded from page 274.)

Leaving the boiler shop we enter the smiths' shop, which is at the present moment undergoing structural alterations. The shop is conveniently arranged for the production of the forgings required in the manufacture of the works products, being served by several steam-hammers, and further equipped with the usual cutting-off appliances, upsetting machine, etc. This shop is 170ft. long by 45ft. wide. From the smiths' shop we proceed to a second power-house. In this building are installed two 8ft. diameter by 14ft. long Paxman patent "Economic" boilers, made for a working pressure of 160lb. per square inch, and having a regenerative combustion chamber at the back, so that any unburnt gases escaping over the bridge are ignited before entering the return tubes, from whence they are carried by means of wrought-iron casing on the front of the boilers to the side flues, and so to the chimney. An electric generating plant, consisting of one steam-driven continuous current set, serves for lighting the offices and stores.

Continuing our round of inspection, we enter the fitting shop, which consists of three 40ft. bays, 100ft. long, devoted to the lighter class of erecting and general fitting. On the left as we enter is noticed one of Davey, Paxman, and Co.'s "Windsor" vertical compound engines, driving the works dynamo, which is temporarily housed pending the erection of a new power-house, which it is proposed to place at the north-east corner of the erecting shop, where the boilers at present installed are used for testing purposes and supplying steam to the machine shop engine. Proceeding to the erecting shop, which is 150ft. long and has a clear span of more than 70ft., many engines and compressors were seen in course of erection. The whole of the floor of this shop is within the traverse of the overhead travelling

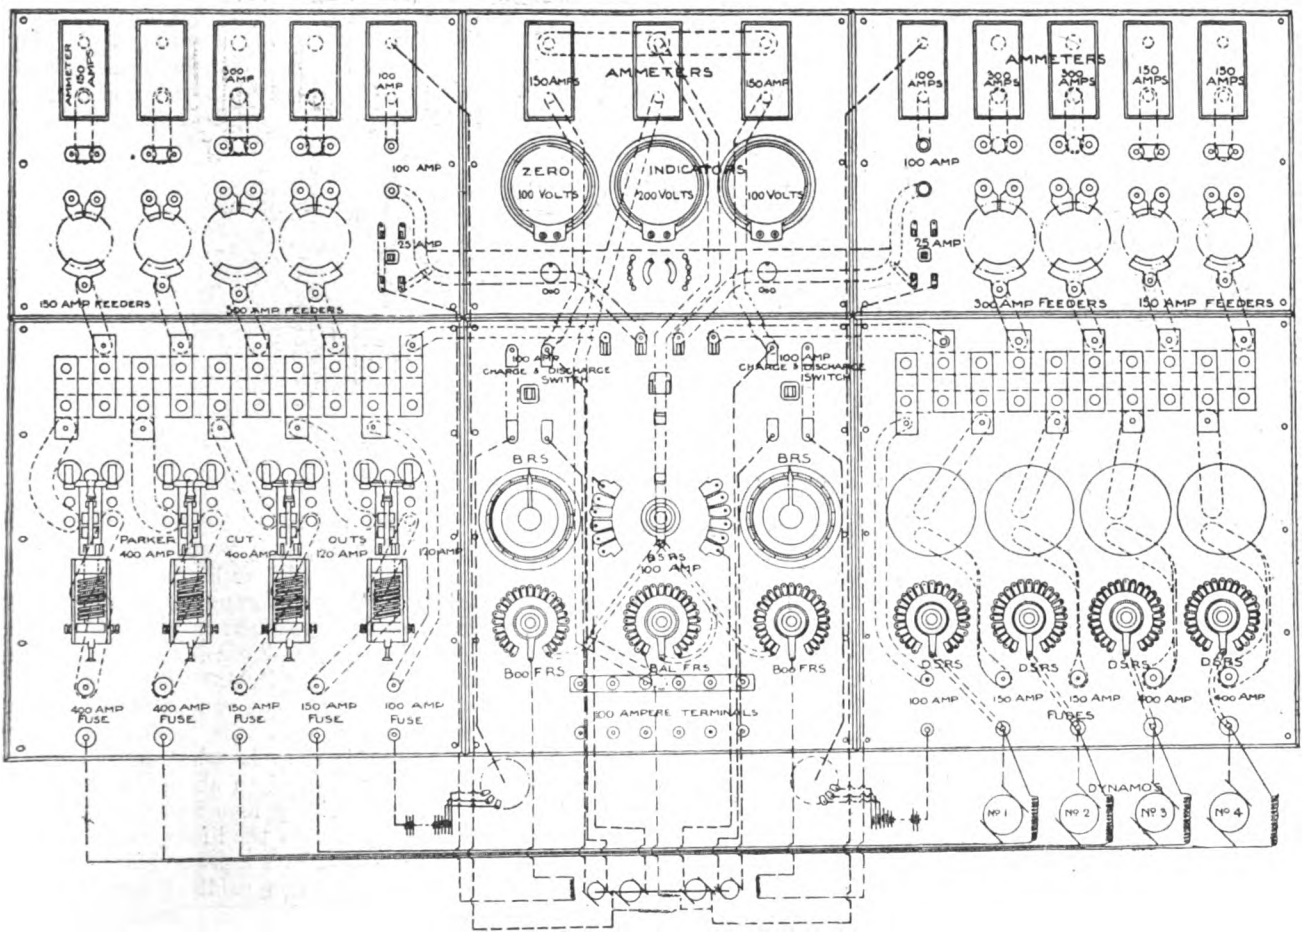

FIG. 6.—Diagram of Switchboard Connections, Edmundson's Guernsey Station.

crane, capable of lifting 20 tons. Amongst the many machines noted in this department may be mentioned a 14in. by 23½in. by 32in. tandem compound engine, driving a compressor; an 18in. by 28½in. by 32in. coupled com-

Digitized by Google

pound engine, driving tandem air-compressors suitable for an air pressure of 60lb. per square inch; a small independent jet condensing plant, consisting of a "Colchester" compound engine with girders extended to carry the air-pumps, which are driven by a prolongation of the high and low pressure rods.

Another of the firm's specialities—namely, the Peache single-acting high-speed engine—was also very much in evidence. Several examples were seen in various stages of progress. The Peache engine is now very well known, and has already been described in these columns, but a few general particulars with regard to the same may be recapitulated. As previously noted, the engine is of the high-speed single-acting type. The steam-cylinders are carried on four wrought-iron columns. They are thus entirely isolated from the working chamber; consequently the bath of oil and water does not get overheated and decomposed, no matter how long the engine is kept at work. No oil can be drawn from the working chamber to the condenser and boilers. There are no internal glands in the engine, and of the external glands one is subject to low-pressure steam only, and the other to exhaust steam only. In case of water in the cylinders, the piston rings act as relief valves and prevent damage. Every part of the engine is readily accessible for examination or repair. The working chamber has large doors, connecting rod, cross-head, and valve motion, or any of these parts can be readily disconnected and removed even in the smallest sizes without dismantling the engine. The valves can be withdrawn by removing the steam-chest cover only. Any high-pressure cylinder can be taken off by breaking one joint only, and both high-pressure and low-pressure pistons can then be removed without further dismantling. The governor with its gear, also steam and exhaust pipes, are all attached to the main cylinder casting. Therefore every part of the engine is accessible without touching the governor gear, steam, or exhaust pipes. This engine has been on the market for some five or six years, and has been largely adopted for electric lighting and power installations, some 15,000 i.h.p. having been supplied for this purpose. At the time of our visit an engine of 260 i.h.p. coupled to a Siemens dynamo was undergoing its steam trial in the testing shop preparatory to its dispatch to the electricity works at High Wycombe. The beautifully smooth and quiet working of the engine was much admired. What most appeals to the engineer is the very substantial character of the various parts which go to make up the engine. Bearing surfaces are evidently very liberally provided for. In the machine shop we noticed the parts of some 550-i h.p. Peache engines which are now being made for the Folkestone electricity station, and which are the largest size so far constructed. Fig. 3 shows a Peache engine direct-coupled to a dynamo.

The testing shed in which we saw the 260-h.p. engine undergoing her tests, though only of a temporary character, is conveniently placed, and equipped with testing beds, independent condenser, measuring tank, and other impedimenta necessary for accurately testing the steam consumption of the various engines manufactured. On the right-hand side is situated the resistance frame, through which the current from the dynamos is passed. This is built up in sections so as to give the requisite artificial load for engines up to 1,000 h.p. When the new boiler-house is completed, it is proposed to build a fresh testing-house to run parallel with the whole length of the erecting shop. Passing through the temporary boiler shed, the machine shop was next reached. This shop is 210ft. long by 124ft. wide, and consists of four bays, two of which are devoted to the lighter class of machine tools, and are each 27ft. wide. The remaining two bays, each 35ft. wide, are filled with the heavier class of machine tools. Light in this shop is taken entirely from the north, and the glazing is equal to about 40 per cent. of the floor area covered. Every man and machine tool in this fine shop is directly within the lifting range of the travelling cranes. In the light bays these consist of handy runner cranes attached to the under-side of the tie-beams of the roof; and in the heavier bays the cranes are rope-driven, being carried on the usual crane tracks. Driving power is obtained from a 120-h.p. "Colchester" compound horizontal steam-engine, placed in the south-east corner of the department. The structure is composed of mild steel throughout, the only inflammable material employed being the roof boarding; hence the fire risk

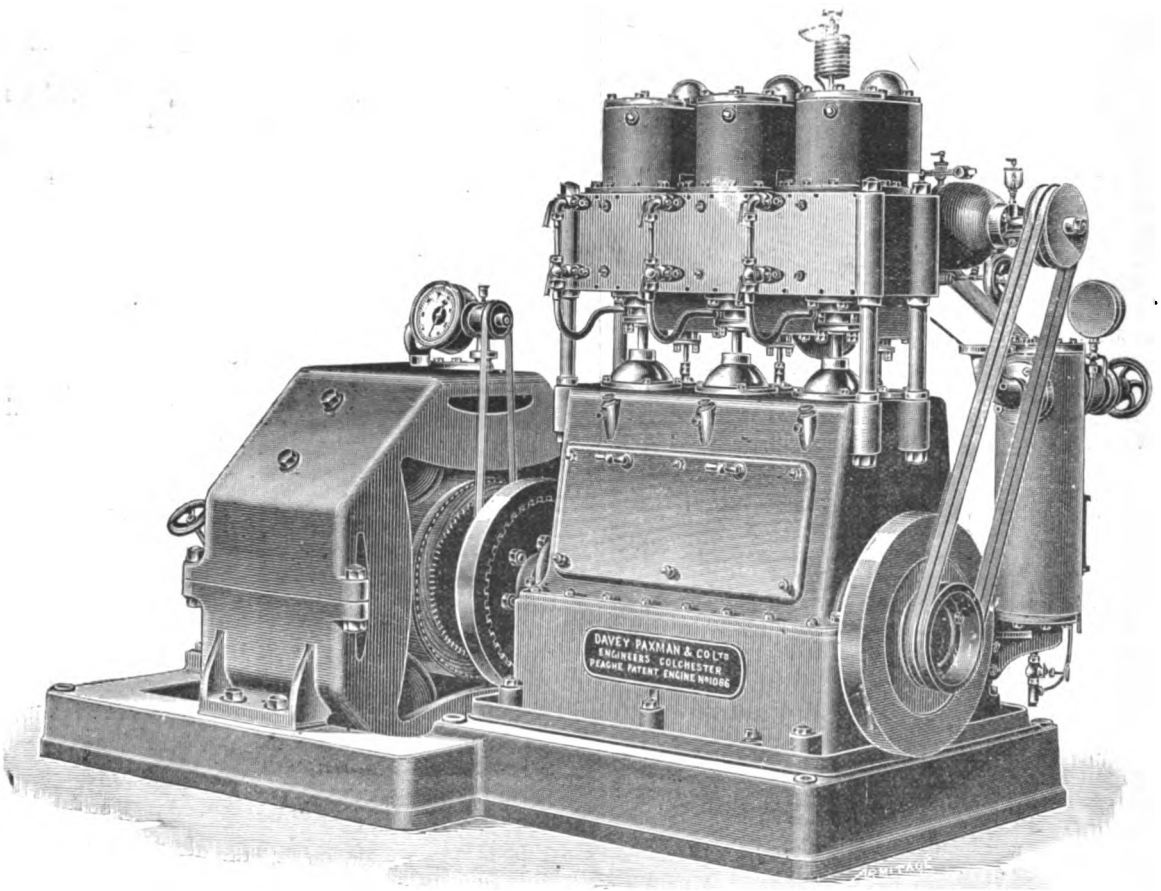

FIG. 3.—Elevation of Peache High-Speed Single-Acting Engine.

Digitized by Google

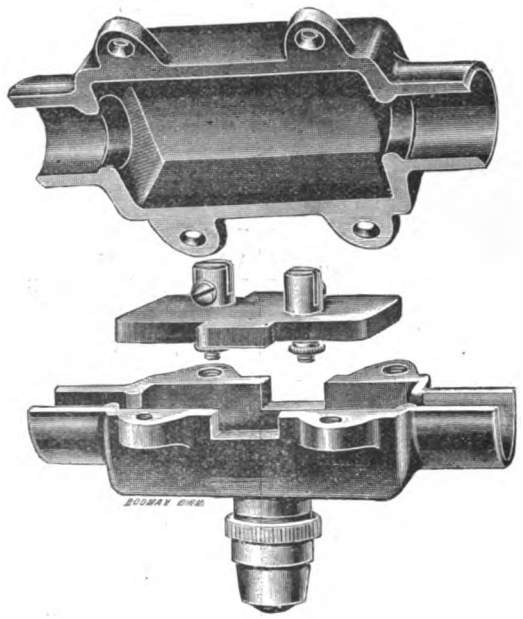
is reduced to a minimum. In the south bay is situated a vertical boring machine of massive proportions, specially designed for machining the high-speed engine cylinders, of which the three bored holes are tooled without rechucking the centres, the correct location of the cylinders being determined by stop-pins in template bars. There is also a lathe equipped with the necessary tackle for machining girder beds up to the largest sizes, performing all the operations required coincidently. The two large boring machines in this bay were made to Davey, Paxman, and Co.'s own designs. A new flywheel lathe, situated in the same bay, is capable of performing at one time and at one setting the whole of the operations necessary for the machining of the flywheels. There is also a large and powerful planing machine in the shop, screw-driven, on which the largest castings required for the works manufactures can be machined. The foundations are being got out to receive a new side-planing machine, having 22ft. stroke, and fitted with two heads, one of which carries two tool boxes. One of the most noticeable tools in the second bay is the crank-pin and dip turning machine, in which the turning tool revolves, held on a ring housed in a concentric frame. This method of turning the crank-pins eliminates all spring usually present when the shaft is revolved on eccentric centres, even when supported by solid eccentric chucks, and the cranks produced by this tool are absolutely correct. In the same bay is a series of special labour-saving tools, consisting of pipe facers and facing machines, double-headed side planers and shapers, drilling machines equipped with tapping and studding machine, a large milling machine, and numerous other tools of interest. In the smaller bay there are eight rows of light machine tools which extend throughout the length of the shop, amongst which are many tools of economical value in the production of the special details for which they have been designed. These tools consist of capstan and turret lathes, automatic screwing machines, milling tools, special brass-turning lathes, grinding machinery, etc. The artificial light for this shop is provided by 40 2,000-c.p. arc lamps.

Illustrating the happy conditions which exist between the employer and the employé at the Standard Ironworks, it may be stated that Mr. Paxman has around him as members of his staff some of those employés who formed the original nucleus of the works now occupying responsible positions in the management. There are quite a number who have seen upwards of 20 to 35 years' service with the firm, and under Mr. Paxman's able guidance the business has grown from small beginnings until there are now employed upwards of 900 men, and with the further extension of the works in view, this number will be greatly augmented during the next few years. Every department of the works is now fully employed, so much so, in fact, that it is found impossible to replenish stocks of standard parts, which are used up as fast as manufactured. Boilers destined for the proposed new power-house, the shaft of which is already in evidence, have thrice been relegated to other purposes, so great is the demand from outside. In connection with the contemplated extensions, it is proposed to construct a branch railway from the works to the main line.

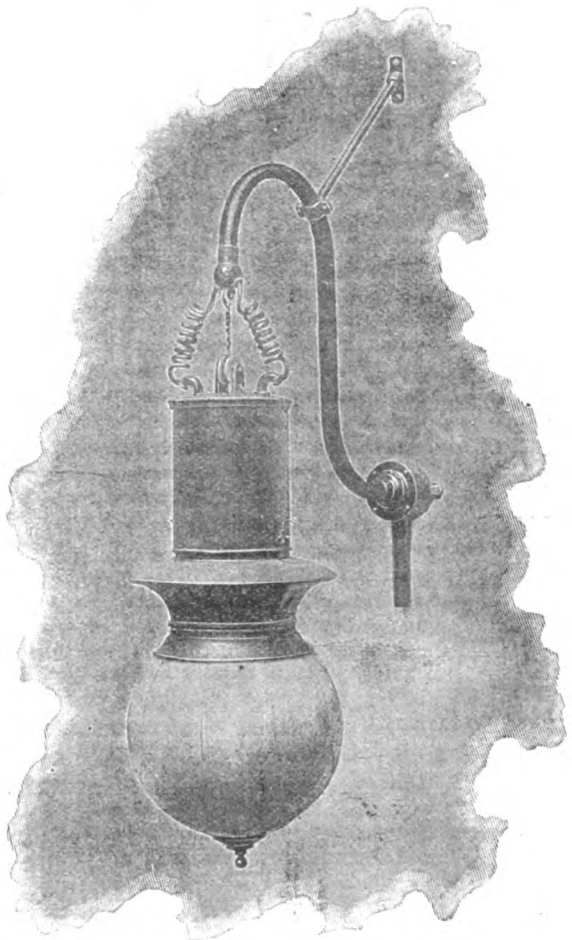
It only remains to be added that the visit of the Ipswich Engineering Society to Colchester proved in every way a complete success, a most enjoyable and instructive evening being spent.

THE SIMPLEX STEEL CONDUIT COMPANY.

We have received from the above company a copy of their new supplementary list, which includes the latest improvements to their steel conduit system. The list is intended to be used in conjunction with the firm's 1900 catalogue. Amongst other things that have recently been added are a screwed brazed conduit of heavy gauge and screwed fittings for use in places such as breweries, etc., where a watertight system is insisted upon; split bends and tee pieces; a new type of box enamelled iron-cased switch and fuse distributing boards; pendant fittings with porcelain bridge with connection terminals fitted. They have also a split box with bridge terminals (of which we give an illustration), and a connection box for connecting up branch circuits from a pair of bars fitted on to porcelain in the box; removable porcelain interiors and connection bars for use with the firm's standard junction boxes are also made. The arrangement in this latter case consists of a



porcelain cradle, which just fits inside the junction box and supports two brass connection bars, which are each made in two parts. The bars are drilled along their length, and terminal screws are fitted to clamp the branch circuit wires, and a half-lap joint in the middle allows the two ends to be easily sweated on to the main lead, it being thimble bored to receive same.



Our second illustration shows one of the Simplex arc lamp brackets, which are made specially strong and watertight for outside use.

The Simplex Steel Conduit Company has, we learn, been awarded a gold medal distinction at the Paris Exhibition.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E C Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	5s. 6d.	10s. 6d.	21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered, price 8s. 6d.

UNPUNCTUALITY.

The inconvenience of the travelling facilities afforded by the railway companies in and around London, and also in the provinces, is a fruitful source of conversation. In fact, if by some means yet to be discovered absolute punctuality in the departure and arrival of trains could be attained, a certain class of the community would be deprived of the subject in which they can best discourse to a casual acquaintance by the half-hour. A certain amount of personal glory seems in these individuals' minds to attach itself to them if, after a mishap on a given railway line, they have been detained an hour or two more over a journey than they would have been if the schedule time had been maintained. It is quite certain that, whatever the improvements in the everyday traffic, no engineering skill or powers of organisation, nor even the miracle-working electricity, will ever be able to avoid the disorganisation which follows a railway accident, in which one or more of the running lines is blocked by heavy *débris*. What, however, can be avoided is the daily inconvenience resulting from either lax management or poorly-equipped lines. The delays in the traffic are always more marked on the suburban lines for two reasons. The first is that the large companies always give preference to the main-line traffic, and a delay in this is hence reflected in the suburban traffic, because the local trains are made to wait for a clear line. The next reason, which practically is an outcome of the first, is that old and inferior engines are used for the suburban traffic. These engines are often only just sufficiently powerful to do their work, so that a slight increase in the load or a greasy state of the permanent way causes delay. There is a further cause, which is alluded to in a leader in the *Times* on Wednesday last, and that is a deficiency in discipline amongst the staffs at the various stations. This applies more to the country stations as a rule than to the suburban ones, but it is also often very marked at the great London termini. In our opinion this laxity of discipline can be explained by the adage, that "He who pays the piper has the right to call the tune." The railway companies allow the general public to pay in tips the greater part of the wages of their porters, with the result that their time is unduly taken up over individual passengers to the detriment of the bulk of the travelling public, and to the discipline of the men. The unrest amongst the staffs of the various railway companies at the present time is most to do with the wage question, and this wage question is intimately connected with the question of tipping. To return, however, to the question of the unpunctuality of the railway companies, we believe that electricity, after all, will afford a solution of the difficulty. On the suburban lines, with their frequent stoppages, locomotives capable of quickly accelerating the trains are needed. The one fact which is most prominently brought out by the trials of the electrical section of the Metropolitan Railway Company is the enormously greater accelerating power of the electrical locomotive over the steam-engine. In cases where the conversion from

Digitized by Google

steam to electricity is not undertaken, the punctuality of the trains and the time taken over the journey can both be improved if an active competition by means of an electric tramway is established. If one compares the schedule times for small journeys round London, it will be found that an average speed on steam railways of eight to ten miles per hour is quite common. This speed can be obtained on an electric tramway, and with a frequency of service which puts the steam railway quite out of court, we hold that competition will in such cases either kill the steam road or else cure it of its crawling propensities. The deep level electric line is, of course, a much more convenient alternative of providing such competition, and where the traffic is dense the capital outlay for such lines is quite warranted. We trust that the success of the Central London Railway will bring financial support to similar schemes, and that the result will be the spread of the population of our great towns over a much larger area than at present.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTROMAGNETIC INDUCTION.

SIR,—You will, of course, agree with me that anything in the way of slip-shod language should be carefully avoided when stating a scientific principle, and you may, therefore, allow me to point out a serious inaccuracy in the statement of a law of electromagnetic induction that is often given by writers who ought to know better. On p. 230 of Slingo and Brooker's "Electrical Engineering," we read as follows: "When a conductor is mechanically moved in a [magnetic] field transversely to the lines of force traversing that field, a certain E.M.F. is determined, which sets up a current in the wire if its two ends are connected." But suppose that a rectangle of wire, facing north and south, is moved northwards across a uniform magnetic field whose lines run eastwards. The vertical sides of the rectangle will then be cutting lines of force. But so long as the rectangle still faces north and south there will be no E.M.F. whatever, because there will be no change in the number of lines passing through it, this number being zero all the time. It will thus be seen that one might design a dynamo which *should* give, according to Slingo and Brooker, an enormous E.M.F., but which *would* give absolutely none at all.—Yours, etc.,

W. F. DUNTON.

FORTHCOMING EVENTS.

WEDNESDAY, SEPT. 5.

British Association.—Annual meeting at Bradford.

SEPT. 18 21.

Iron and Steel Institute.—Paris meeting, Sept. 18, 19, 20, and 21

Sept. 17.—Secretaries' office opens at the Société d'Encouragement pour l'Industrie Nationale, 44, Rue de Rennes, at 3 p.m. 6 p.m., meeting of council at Mr. Henry Chapman's office, 10, Rue Laffitte.

Sept. 18.—9.30 a.m., reception of the president in the hall of the Société d'Encouragement; reading and discussion of papers. 2 p.m., visit to the Exhibition. 9 p.m., Soirée Musicale et Littéraire by the Comité des Forges de France.

Sept. 19.—9 30 a.m., general meeting in the hall of the Société d'Encouragement; reading and discussion of papers. 2 p.m., visit to the Exhibition. 7 30 p.m., the Institute entertains the Reception Committee at a banquet at the Hôtel Continental, Rue Castiglione.

Sept. 20.—10 a.m., visit to the exhibition at Vincennes (locomotives, railway plant, and machine tools). 8 p.m., Group A will start for the St. Chamond Works. 10 p.m., Group B will start for the Hayange Works.

THE SUBMARINE TELEGRAPH JUBILEE.

Articles have recently appeared in the London daily Press respecting the jubilee of the submarine telegraph, the first great experiment being carried out in 1850, and cablegrams having passed between France and England on Aug. 28 of that year. The pioneers of the submarine telegraph were John and Jacob Brett. These formed a company to lay a cable on the French coast. They obtained a concession from the French Republic, and the company, consisting of Mr. J. W. Brett, Mr. Charles Fox, Mr. Francis Edwards, and Mr. C. J. Wollaston, undertook to lay the cable by Sept. 1, 1850. Of these four gentlemen, Mr. Wollaston, who is still alive, acted as the engineer to the company. Directly on arriving in England from Paris after obtaining the concession, Mr. Wollaston arranged with the Wiremakers' and Guttapercha Company for the supply of materials. He also had a drum constructed from which to pay the cable out from the ship's deck. On a tug this drum, on which was wound 24 miles of wire, was fitted, and, says the *Times*, on the morning of Aug. 28, 1850, the tug was at Dover. A coil of wire was twisted round a pile belonging to the harbour works and then carried up above to a horse-box, which the South-Eastern Railway Company had lent the Submarine Cable Company to serve as their Dover office. The tug then started off in a straight line for Cape Gris Nez. The cable was weighted with small pieces of lead to keep it down, and was sunk without accident, the other end being made fast in an old custom house on the French cliffs. Considering the imperfect insulation, the simple method of keeping the cable down, and the strain that was put upon the unsupported guttapercha wire, it seems a wonder that the experiment succeeded at all. But succeed it did, and proved that the promoters had, so far as they could, gone the right way to work. The instrument in the horse-box at Dover railway station clicked out a message to Louis Napoleon congratulating him upon the happy result of the experiment. The cable, however, naturally soon ceased working, but the fact that communication could be made was proved, and another concession was given. In order to work this the Submarine Telegraph Company was formed, which laid down a four-wire cable, with strong wire insulation, and on Nov. 13, 1851, this was opened for public use. Submarine communication was now a well-established fact, and in 1853 the England-Ireland cable was laid, quickly following which was the Dover-Ostend cable. It was not, however, until 1858 that the Atlantic Telegraph Company supplied communication between America and England. Since that time cables have been laid in all parts of the world, and submarine communication has developed to such an extent that if it were suddenly cut off to the average business man nowadays, life would hardly be bearable.

THE EVOLUTION OF SWITCH GEARS FOR HIGH-PRESSURE ALTERNATING CURRENTS.

BY W. E. WARRILOW.

(Continued from page 276.)

Figs. 23 and 24 are photographs of a large board fitted with Lowrie-Hall switching appliances which has been in use at the Leeds Corporation electricity works for some years past. One photograph shows almost the whole board, and the other a few panels. In Fig. 23 the ammeters in the immediate foreground are in the exciter circuits, and below them will be seen the rheostats fixed on a table in front of the main board. At the top of the high-pressure board are the dynamo fuses, synchroniser bases, and leakage indicators; below are four rows of plug switches for dynamos and circuits, and at the bottom of the whole the circuit fuses.

Fig. 25 is a diagram of the connections of a portion of the board, which will serve to illustrate the general arrangement. It will be seen that there are two bus bars, on to either of which any dynamo or circuit may be switched—there are no actual bars in the rear of the board, but the

Digitized by Google

machines and circuits are coupled as though there were, and the diagram has been drawn up in this manner to make the connections as plain as possible—and these bars may be

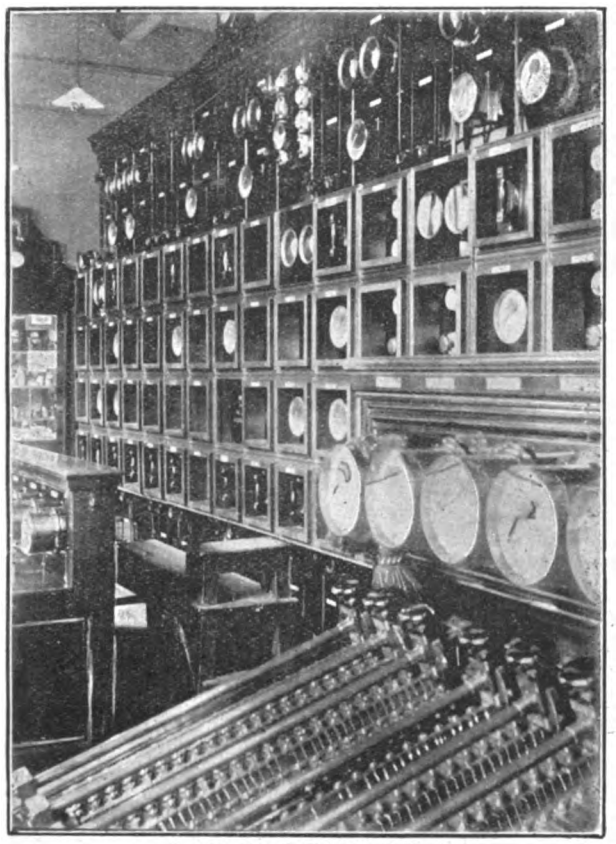

FIG. 23.—Lowrie-Hall Board, Leeds.

sectionised so that a particular dynamo will feed a particular circuit. Any machine cannot, however, be run on any circuit. If all the machines are run in parallel, the discon-

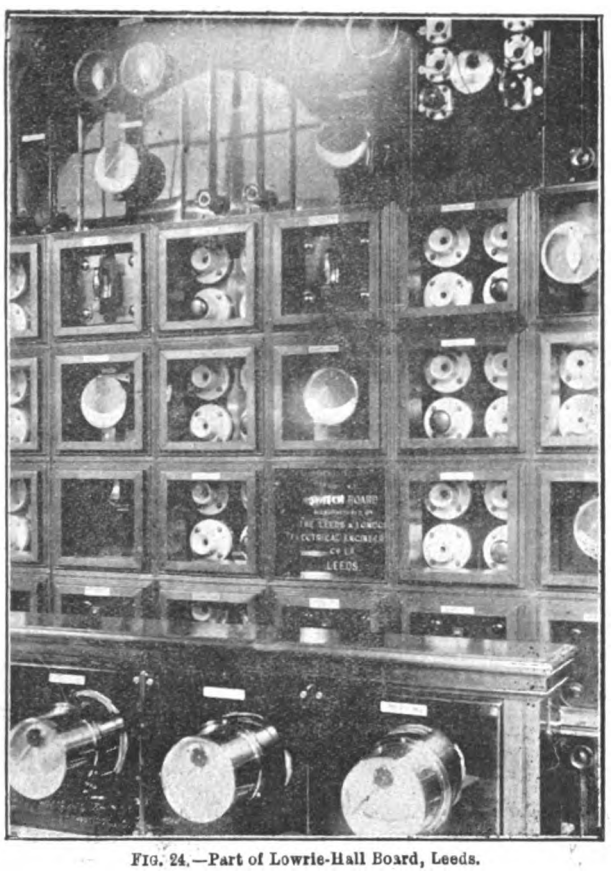

FIG. 24.—Part of Lowrie-Hall Board, Leeds.

necting switches are all left closed, and two circuit switches are plugged in to couple the two bars together. The duplicate bars necessitate the provision of two plug switches for each dynamo and circuit. All connections are made at the back of the board by means of rubber-covered cables, arranged as circumstances and space will allow.

Messrs. Fowler have recently introduced a high-tension

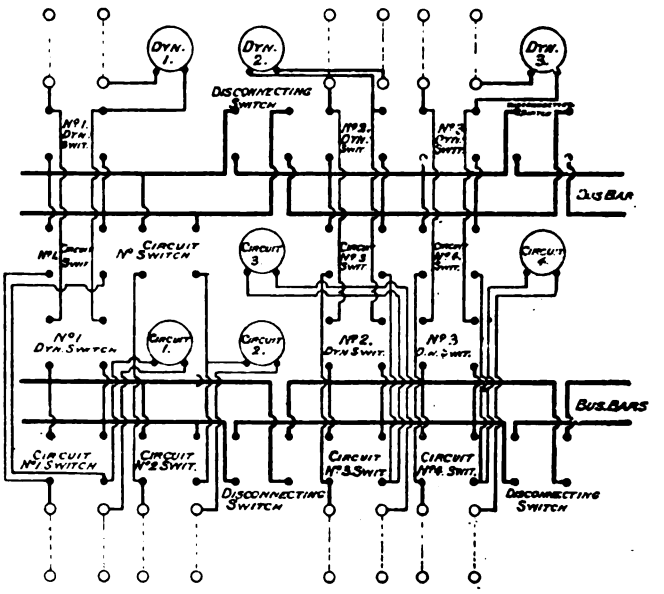

FIG. 25.—Diagram of Connections, Lowrie-Hall Board, Leeds.

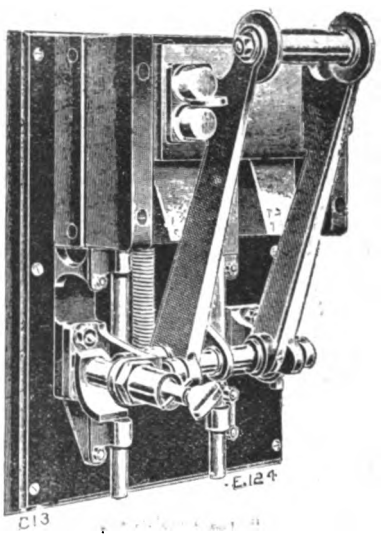
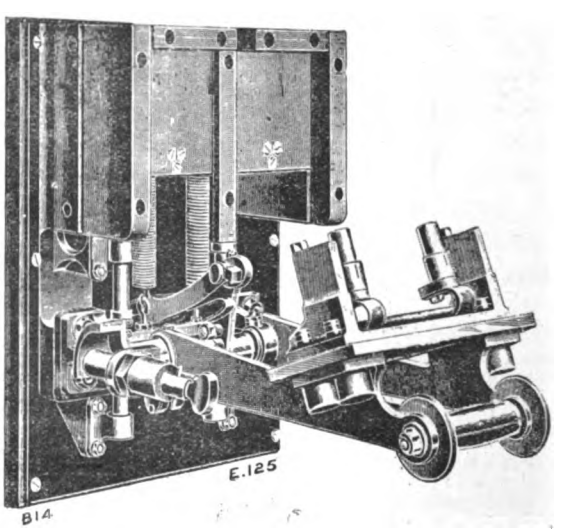
shutter switch for breaking heavy currents. Fig. 26 illustrates this switch, open and closed. The base of enamelled



SWITCH CLOSED.



SWITCH OPEN.

FIG. 26.—Lever Shutter Switch.

slate carries two socket terminals mounted in heavy porcelain insulators. These terminals are fitted at the back with sweating thimbles and at the front with spring jaws and spring-pressed carbons. Fixed to the base slate are the

Digitized by Google

brackets for the level centres and shutter guide rods and the guard slates. The lever of the switch comprises two brass arms, pivoted at their lower ends on a spindle and fastened at their upper extremities with the handle, and an insulated bridge

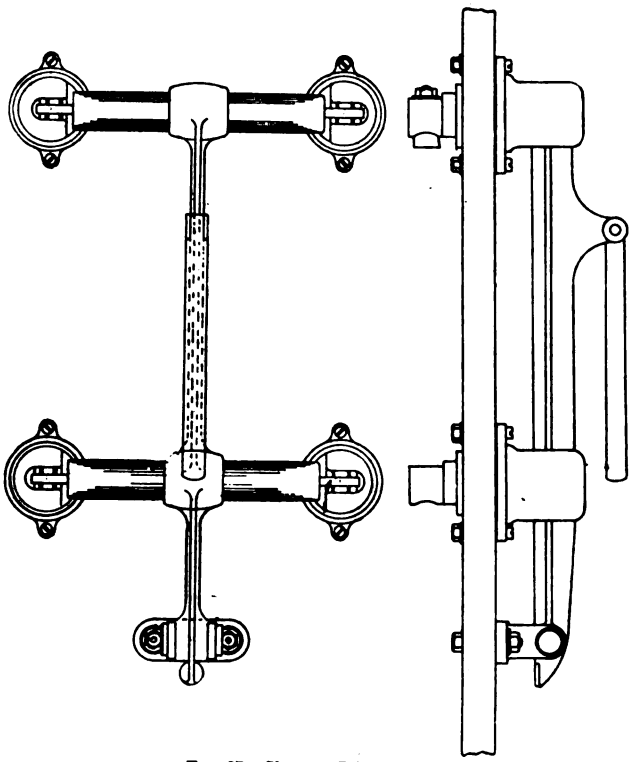


FIG. 27.—Siemens D.P. Switch.

contact fitted with carbons. A shutter is arranged for each contact, and each is mounted on brackets and guide rods, the latter being joined by a cross-piece. The shutters are firmly held by two springs against the top guard, and they

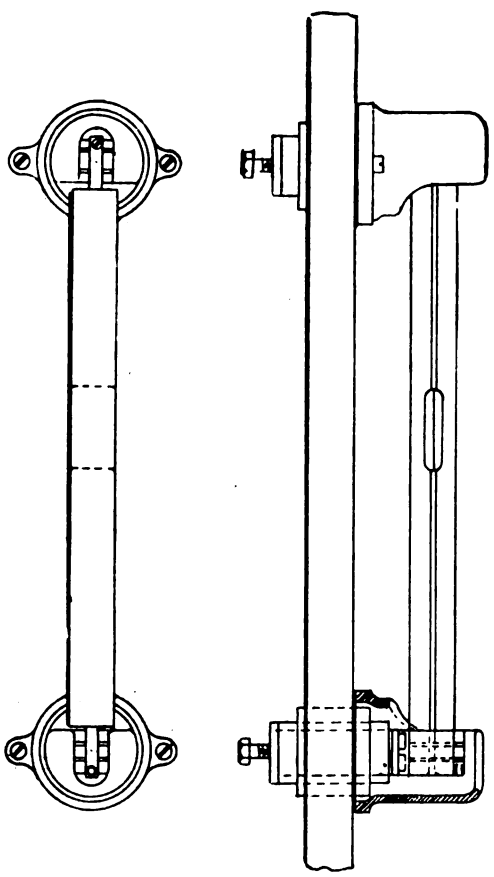

FIG. 28.—Siemens H.T. Fuse.

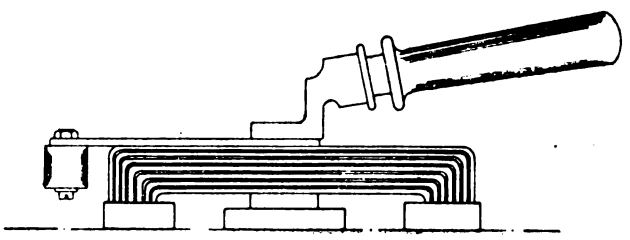
are further guided by grooves suitably arranged in the side guard slates. The switch is opened by pulling down on the handle fixed to the lever. The ends of the connecting bridge will first be drawn from the contact jaws, leaving the carbons pressed together, until the holder of the spring-pressed carbon, which telescopes into a tube, comes to its limit of travel, when the final break will take place at the carbons. At this moment the shutters will be released and fly up to break any arc which may be forming, and at the same time close in the "live" parts of the switch. When the lever is in the "off" position there is no danger from shock at the bridge contacts, as these are only in circuit during the time the switch is closed. In closing the switch the shutters are caused to moved downwards against the tension of the springs attached to them, and to thus uncover the contact jaws to receive the connecting bridge. When the lever is finally pushed home, the shutters are pressing against the underside of the contact plugs, ready to fly up when the switch is opened. A locking device and synchronising contact are fitted to the switch, and it is a noticeable feature of the apparatus that neither in the on or off positions is it



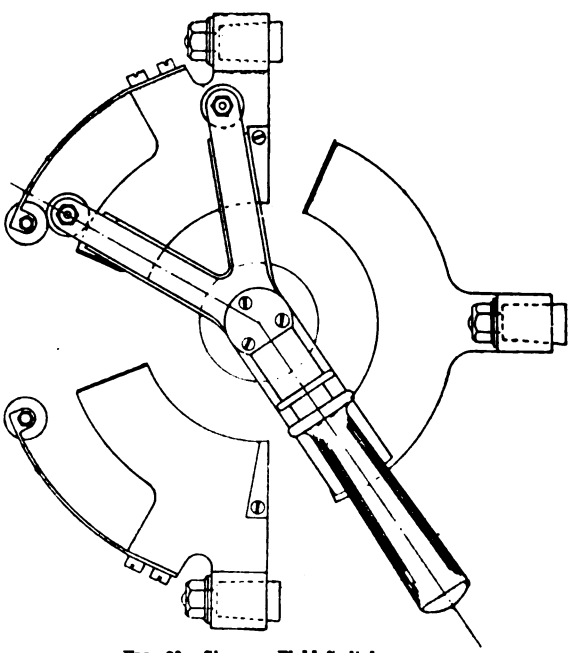


FIG. 29.—Siemens Field Switch.

possible to touch any "live" part. It is constructed to break currents up to 1,500 amperes at 2,000 volts.

SIEMENS.

Messrs. Siemens Bros. have equipped many alternating-current stations in this country, and consequently have fitted up a number of switchboards. Like almost all early gears, they erected double-pole boards, but since the earthing of the outer has become generally adopted the switching arrangements are confined to one pole. The gear resembles those before described, also, in that all connections are made at the back, which is rendered accessible by building the board up some distance from the wall. A double-pole switch suitable for breaking high-pressure currents up to 350 amperes is shown by Fig. 27. The contacts consists of copper spring clips screwed to brass shanks, which are enclosed in porcelain tubes, these latter thoroughly insulating the fitting from the slate. The shank is provided with cable attachment at the back. Each contact is covered by a porcelain hood, which serves the double purpose of confining the arc and preventing accidental contact should anyone stumble against the panel. The hoods are provided with a slot, to allow the switch blade to enter the contact. The blade is formed of a copper bar, enclosed in a porcelain tube, which is firmly fixed in the

Digitized by Google

switch lever, and the ends of the bar project from the tube to allow of contact with the clips. When the switch is open there is no danger of shock from touching these ends, as they form no part of the circuit, except when the switch is closed. The switch lever has a hinged handle attached to it to facilitate the quick opening of the circuit, and to keep the hand of the operator clear of any arc which may form. A double-pole switch to break circuits up to 75 amperes is also made, but the handle is similar to that shown attached to the switch on the complete panel (Fig. 30) The lower end of the switch arm is pivoted in a bearing attached to the slate, and it is also provided with an extension at this end, which strikes against a rubber stop set in the bearing casting. This damps the blow of opening the switch quickly, also serving as a stop to the arm.

A high-tension fuse capable of safely opening a circuit of 250 amperes capacity is shown by Fig. 28. The contacts are precisely similar to those used in the switches, but are arranged vertically instead of horizontally. The fuse wire, which has a length of 18in., is embedded in a slate bridge of square section, a groove being run down its length for the reception of the fuse. Gunmetal blocks are fitted at each end of the bridge, and to these the fuse is firmly screwed after passing through a hole in the block. A slight hole is provided in the centre of the bridge for purposes of examination. The fuse is inserted in the contacts by slight pressure, and is held in position by the spring clips.

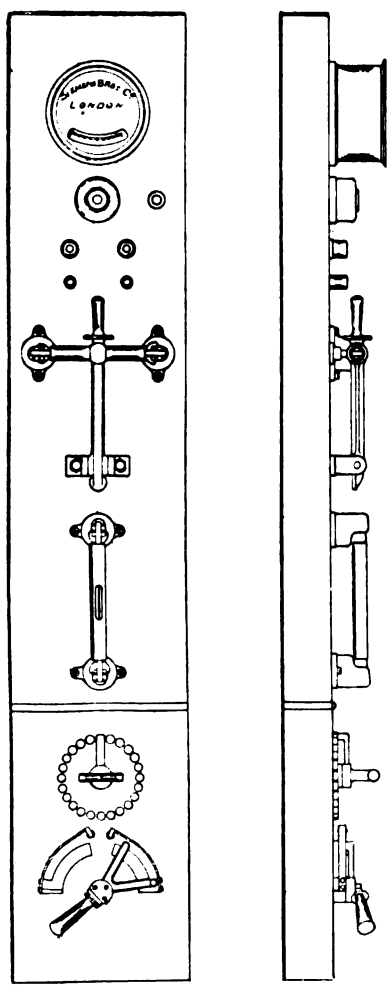

FIG 30.—Siemens Single-Pole Alternator Panel.

A carbon break switch for breaking the field circuit is shown in Fig. 29. This type is intended for use with heavy currents and connections at the front, but where smaller currents are dealt with, the lower contact segment is not used, the centre bearing of the switch acting as part of the circuit. The switch is a two-way one, the segments being joined together by a slider of copper laminations actuated by a handle of ebonite. The bridge is pivoted at its centre, where it is also divided into two parts, which take the shape of a Y. The two arms thus formed are fitted with carbon rollers so arranged that they engage with other rollers fastened on springs to the contact segments. These carbons take the break of the circuit, and when burned away can be easily renewed. The lower segment is connected to the alternator field, the right-hand to one pole of the exciter, and the left-hand to the other pole through a non-inductive resistance. Connected in this manner with the switch in the position shown in the drawing, the field circuit will be closed. When in the intermediate position, with the brush connecting both segments, the field and non-inductive resistance are placed in parallel across the exciting source, and when put over to the left the field is short-circuited by the non-inductive resistance.

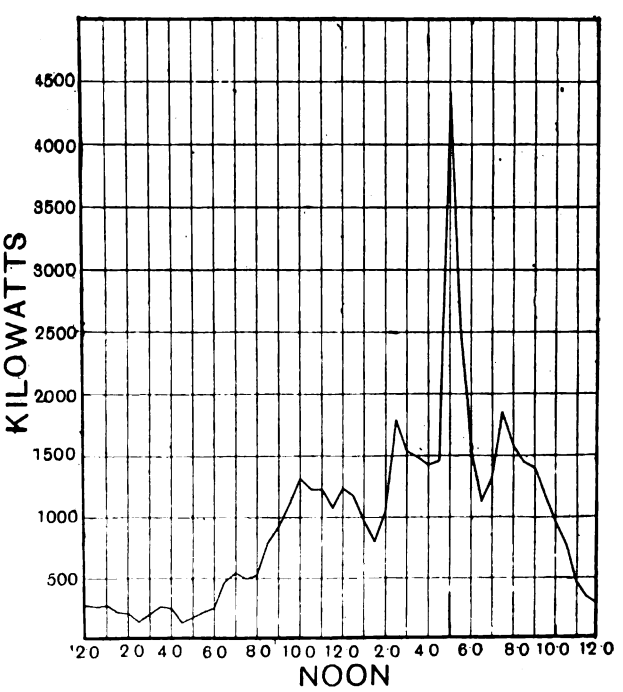
Fig. 30 illustrates a complete panel with high-pressure switching arrangements on one pole. The primary ammeter is fixed at the top of the slate, with a short-circuiting plug and holder below it. Lower down are the synchronising sockets, with a rest for the plug below them, and beneath these are the main switch and fuse. At the bottom of the panel is the exciter slate, separated from the primary slate by a thickness of ebonite. This slate has a rheostat and field switch as above described mounted on it.

Such panels are mounted in a wood framing, finished with teak or other mouldings, and arranged with space between the slates and wall for examination or alteration of the connections.

(To be continued.)

A MANCHESTER LOAD CURVE.

Through the courtesy of the Corporation electrical engineer, Mr. C. H. Wordingham, we are able to reproduce in this issue a unique load curve, which was taken on Tuesday, Aug. 21. On that day a very heavy thunderstorm passed over the city of Manchester, which caused a very sudden and heavy increase in the load. This load curve, in fact, would be a useful record to a meteorologist in tracing the progress of the storm, as it fixes the exact point at which



Load Curve for the Dickenson-street Station at Manchester for Aug. 21, 1900.

darkness commenced and ended. It will be seen from the curve that the ordinary load of about 1,750 kw. was supplied in the usual way at about half-past two, due, we presume, to the light required in restaurants, and that at half-past four the storm began to make itself felt. The load rapidly increased to nearly 4,500 kw., or approximately three times its normal volume. Such a sudden increase was a great tax on the steam-raising plant, and we learn from Mr. Wordingham that the pressure at the boilers could not be maintained. He, however, succeeded in maintaining the voltage on the lamps, for which every credit should be given to the engineering staff of the Dickinson-street station. The

Digitized by Google

unfortunate consumers in the City of London know what disastrous effects a thunderstorm has on the voltage of electric supply in that area.

ON THE EFFECTS OF STRAIN ON THE THERMO-ELECTRIC QUALITIES OF METALS.—PART II.*

BY MAGNUS MACLEAN, M.A., D.SC.

A.—*Thermo-electric difference between free wires and wires previously subjected to longitudinal extension and lateral compression, by drawing them through the holes of a draw-plate* (§§ 1-17).

§ 1. In Part. I of this paper, read to the society on Feb. 2, 1899, the object of the experiments was stated to the determination of the magnitude of the thermo-electric effects, obtained from any one metal strained and unstrained. The results then given were obtained from two wires of the same material, one wire being previously drawn through a draw-plate, so as to reduce it in size from No. 18 standard gauge (0·122cm. diameter) to about No. 24 standard gauge (0·0559cm. diameter). The arrangement of the experiments to measure the thermo-electric effect is shown diagrammatically in Fig. 1. One junction of the wires was kept in a glycerine bath, which could be heated by a Bunsen burner. This junction was tied by a fine copper wire to the bulb of a thermometer, T. The other ends of the wires were joined to short

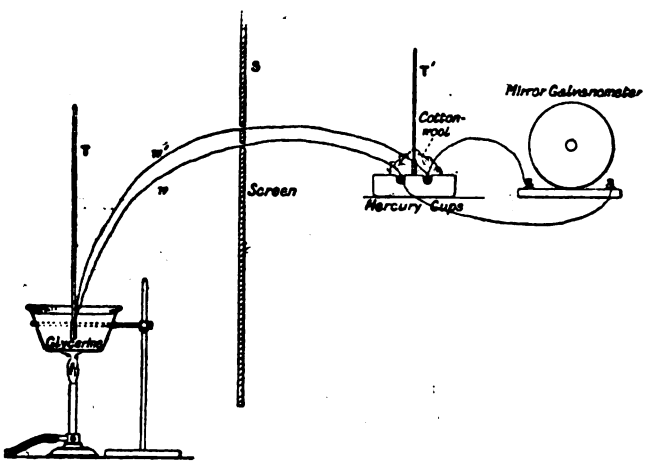


FIG. 1.

copper wires, which served as terminals of the low-resistance galvanometer used in the experiments. These junctions were wrapped in paraffin paper or cotton wool, which contained the bulb of a thermometer, T', reading half degrees from 0deg. C. to 25deg. C. A paper screen, S, was hanging vertically between the Bunsen burner and the thermometer T' and the galvanometer, to prevent any heat from the flame reaching the rest of the circuit by radiation. These precautions were taken to make certain that all junctions, except the hot junction, would be at the same temperature. The sensitiveness of the galvanometer was 0·09 mikroampere per division, and as its resistance is 1 5 ohms, the E.M.F. at its terminals was 0·135 mikrovolt per scale division.

§ 2. The metals for which results were given in Part I. were copper (six specimens), lead (two specimens), platinoid, German silver, reostene, and manganin.† The present paper gives results of similar experiments made on specimens of commercial‡ and pure lead, obtained from Messrs. Johnson and Matthey; and specimens of annealed steel, of aluminium, and of nickel.

§ 3. The method of experimenting was to take a piece of the wire and draw it through a few holes of a draw-plate so as to reduce its cross-sectional area to about a quarter. Then two pieces of the wire, one drawn and one undrawn, each 60cm. long, were joined as in Fig. 1. The glycerine bath was very slowly heated by the Bunsen burner. When there was a rise of temperature of 5deg. C., the Bunsen burner was drawn slightly aside so as to give as much heat to the glycerine bath as it lost by radiation. When both the thermometer reading and the spot of light on the scale were seen to be steady, the readings were noted. The circuit was then broken and readings taken of the galvanometer zero and the thermometer T'. The circuit was again completed, and readings taken when there was 5deg. C. further rise of temperature, and so on up to a difference of about 100deg. C., the greatest difference tried in these experiments. A curve was plotted with differences of temperature between the hot and the cold junction as abscissæ and currents through the galvanometer as ordinates. The mean current per degree difference of temperature as found from each curve is given in Table I.

TABLE I.

Conductor.	Condition of conductor. Current from 1 to 2 through the hot junction.	Current in mikro-ampere per degree up to 100deg. C.
Annealed steel	1. Drawn 2. Undrawn	0·0567
Aluminium	1. Drawn 2. Undrawn	0·0065
Nickel	1. Drawn 2. Undrawn	0 213
Lead, commercial	1. Undrawn 2. Drawn	0 0124
Lead, pure	1. Undrawn 2. Drawn	0·0036

§ 4. The steel was annealed by coiling it round a large cast-iron ball, which was heated in a bright coal fire for about an hour. After being taken out of the fire, the ball, with the iron wire round it, was allowed to cool slowly for about an hour and a half in the ashes below the fire. It was previously found that heating the wire to red heat by an electric current and allowing it to cool slowly did not anneal it.

TABLE II.

Conductor.	Cross-section of undrawn and drawn wires in sq. cm.	Specific gravity of undrawn and drawn wires.	Resistance of the undrawn wires in C.G.S. units at 14deg. C.	
			Per c.c.	Per cm. long, weighing a gramme.
Steel, annealed	0 007504 0·004141	7·78 7·762	13,900	108,100

Lead, pure	0 1059	0·5162	0 6221	2·12	0·0076

§ 5. The resistances of all the undrawn wires, and the

* Paper read before the Royal Society.

† Dr. Anderson, Chemical Laboratory, the University, Glasgow, gave me the following analyses for reostene and for manganin:

Reostene.		*Manganin.*	
Si	0 61 per cent.	Sn	0 073 per cent.
Fe	79 95 ,,	Fe	0·6 ,,
Ni	16·53 ,,	Cu	86·62 ,,
Mn	1·21 ,,	Mn	8 031 ,,
		Ni	3·261 ,,
Total	98·30 ,,	Total	98·585 ,,

‡ Dr. Anderson analysed the commercial lead and found it contained 99·12 per cent. of lead.

Digitized by Google

specific gravities of both the undrawn and drawn wires, were carefully determined by the usual laboratory methods. The results obtained are given in Table II.

§ 6. By multiplying the current per division given in Table I. by the total resistance in the circuit, calculated from the results in Table II, the thermo-electric difference per degree between drawn and undrawn wires is found. The numbers are given in Table III.

§ 7. The thermo-electric difference between glass hard tempered steel, annealed steel, and unannealed steel was found by similar experiments to be:

1. Glass hard steel
2. Unannealed steel } 7·5 mikrovolts per degree C.
1. Unannealed steel
2. Annealed steel } 0·18 " "
1. Glass hard steel
2. Annealed steel } 7·67 " "

The direction of the current through the hot junction was in every case from hard steel to soft steel.

B.—*Thermo-electric difference between free wires and wires previously permanently elongated by longitudinal stresses* (§§ 8-10).

§ 8. Attempts were now made to determine the thermo-electric difference between free wires and wires previously permanently elongated by a longitudinal stress. It was found difficult to elongate the hard wires permanently to any appreciable extent before they broke. Several methods for stretching the wires were tried, and the method finally adopted was to take two pieces of stout copper rod, bent into the shapes shown at A and B in Fig. 2, and to wind the wire to be stretched several times round A and B.

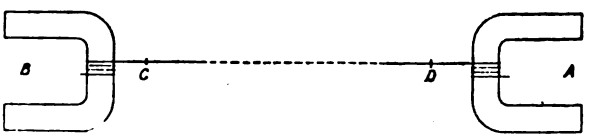

Fig. 2.

The end A was clamped in a fixed vice, and the end B fixed in the clamp of a screw arrangement. By turning the screw the wire was stretched tight. Two ink marks were then put on the wire at C and D 60cm. apart. The screw was very slowly turned, and the distance between C and D measured until the necessary elongation was produced or until the wire broke. The wire generally broke where it lay tangentially to either rod A or B.

§ 9. The greatest percentage permanent elongation that could by this method be got in hard-drawn copper, manganin, nickel, and German silver, was 0·7, 0·5, 0·7, and 0 5 respectively. The thermo-electric difference between the stretched and the unstretched wires was then determined, as described in § 3, and the results are given in Table IV.

§ 10. It will be noticed that the current is from unstretched to stretched, through the hot junction for three specimens of copper, and from stretched to unstretched through the hot junction for other three specimens. The probable explanation of these results is suggested in §§ 13, 14, 15.

C.—*Thermo-electric difference between free wires and wires under stress, producing* (1) *temporary elongation*, (2) *permanent elongation* (§§ 11-18).

§ 11. The arrangements shown diagrammatically in Fig. 3 were now made to determine the thermo-electric difference between free wires and wires while (*a*) under stress, stretching them within their limits of elasticity, and (*b*) under stress, stretching them beyond their limits of elasticity. A B is a brass tube through which steam from a kettle is allowed to pass. The wire under test is wound round this brass tube three times, and then round a small brass tube in the triangular frame below, and then to one of the terminals of the galvanometer. The wire is thus quite continuous, from one terminal of the galvanometer to the other terminal. Some cotton wool is loosely packed at the hot junction of the wire to ensure that the temperature of the wire is at steam temperature. The weight of the triangular frame (two sides wood and one side brass tube) with its hook for hanging weights on was 220 grm. This is the smallest weight used for each wire, everyone of which was about No. 30 S.W.G. (diameter, 0·315cm.).

Table IV.

The object of the small brass tube in the triangular frame was to keep the temperature of the cold junction at any determined temperature by allowing water or other fluid to flow through it. In all the experiments hitherto made, the temperature of the cold junction was taken as the temperature of the air at the time of each observation.

§ 12. The experiments were performed as follows: The wire was put into the circuit, as shown in Fig. 3. After

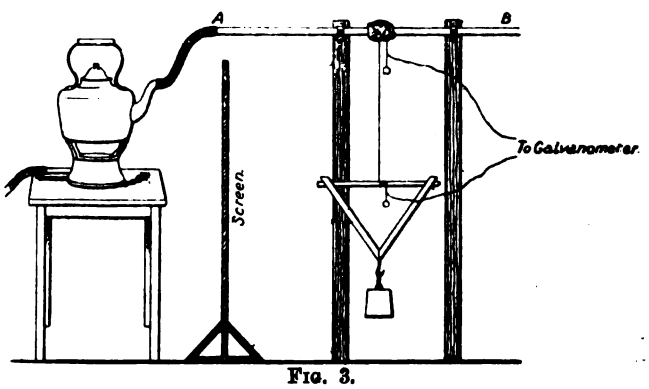

Fig. 3.

steam was allowed to pass through the tube for some time, the galvanometer reading and the air temperature were taken. The circuit was then broken, and the metallic zero of the galvanometer was noted. The circuit was made, and a weight was added on to the hook of the triangular frame. Three readings of the galvanometer were now taken: (1) with the weight on, (2) with the weight off, and (3) with the circuit broken. A heavier weight was hung on and other three readings taken, and so on to the heaviest weights used in the experiments.

§ 13 The readings of the galvanometer were in the same direction for all the wires tried with weights on and off, except for soft copper and iron. The greatest permanent elongation produced in any of the hard copper wires experimented on was 0·17 per cent., and for this permanent elongation the reading on the galvanometer was in the same direction for weights off and on, though always greater for the latter.

ELECTRICAL MEASURING INSTRUMENTS.*

BY J. FRANKLIN STEVENS.

In attempting a brief discussion of so broad and comprehensive a subject as that assigned me for this evening, I have been principally concerned in trying to decide just what portion of the general subject I should touch upon, and in what manner I could treat that portion briefly, for I cannot hope to be comprehensive and yet have my remarks present a semblance of coherence.

Since we have available a very extensive literature bearing on the subject of laboratory testing instruments, in which can be found descriptions of the instruments employed, their construction, application, and approximate laws, I shall pass over that portion of the subject and confine myself to commercial direct-reading indicating instruments, such as are to be found in everyday use.

The history of the art embodied in the commercial manufacture of indicating instruments is extremely interesting, but shows many analogies to the development of other branches of electrical engineering, with the single exception that practical data in published form is extremely scarce. Everyone entering this field is compelled to master some of the most intricate problems known to the profession, and must learn for himself how best to apply theoretical deductions to practical mechanical devices. Until very recent years our sole guide has been the study of early and primitive types, which in their time were useful and valuable, but which to-day fail to reach the high standard we have learned to demand of an instrument whose function is to indicate the input or output of our many and varied electrical devices. Every new device put before the public has meant a new condition to be met by the instrument manufacturer, requiring of him a new design or modification of an existing design. Two rather recent examples of this occur to me: one, the increasing tendency to employ high voltages in commercial work, reaching frequently 12,000 volts in the case of series constant-current arc-light systems and 33,000 volts in long-distance power transmissions; the other, the rapid development of the electric automobile, which requires a volt-ammeter of as high a degree of accuracy as the portable laboratory instrument, yet able to withstand the roughest usage ever accorded an instrument of precision, coupled with restrictive specifications as to size and weight. In every instance instrument manufacturers have met the demand made upon them better, I think, than many of our fellow-workers have in some other lines. Much yet remains to be done, and much, I am confident, will be done in the matter of perfecting existing instruments in the near future. Gradually inefficient or unreliable types are being relegated to oblivion, and the remaining ones brought closer and closer to staudard uniform construction.

The greater number of measurements required to-day can be made with a voltmeter, ammeter, and wattmeter, and, while it might be thought that the wattmeter is merely a combination of the voltmeter and ammeter mounted in one case, this is not true in all classes of measurement. While it is true that the reading of the wattmeter represents the product of the readings of the voltmeter into the ammeter in the case of direct-current measurements, it is not true in the case of alternating-current measurements, save in the very exceptional case of a circuit possessing neither capacity nor inductance or a balance of the two. When either inductance or capacity exist, there is a consequent lag or lead of the current wave relative to the pressure wave, and, since the instantaneous readings of the volts and amperes represent the mean effective or virtual values—that is, the square root of the mean square—their product differs from the reading of the wattmeter, which indicates the integrated values of two curves, the maximum and minimum values of which occur at different times. To obtain an agreement between the values obtained by volt-ampere readings and watt readings, it is necessary to multiply the volt-ampere readings into the cosine of the angle of lag or lead, so that the ratio of the watt readings, as given by a properly-constructed wattmeter, to the volt-ampere readings gives us the power factor of the circuit, and from the two sets of readings we can readily determine the angle of lag or lead and the so-called wattless current. Probably this is well known to all of you, yet scarcely a week passes but I have to explain the matter to one or more customers, who cannot reconcile the difference in the two sets of readings, and are inclined to believe that some, if not all, of their instruments are indicating erroneously.

Before touching on the different types of indicating instruments which are most commonly found in commercial use, let us consider for a moment the essential requirements of a practical and satisfactory instrument for measuring voltage, current, or power. To start with, the instrument must be direct-reading. We have no time to-day to convert angular deflections into true values by means of tables of constants, but insist that the pointer shall indicate directly in definite units the value of the passing load or the impressed E.M.F. We must next be assured of the accuracy of the calibration, and for that depend principally upon the reputation of the maker or check the indications by comparison with a secondary standard. Beyond this we must know that the accuracy of the indications is not affected by the influence of ordinary external fields or by normal variations of temperature, due either to heating within the instrument, by means of the passage of the current to be measured, or to variations in the temperature of the room in which they are installed. All instruments should be mounted in dust proof cases, and the systems carried in jewelled bearings; the movement of the pointer should be aperiodic or dead-beat, and, so far as possible, the system should contain nothing subject to change or deterioration, and should be constructed so that it will withstand successfully the ordinary rough usage liable to be accorded it in practice. The question of gradual change of accuracy, due to the change in some constituent part of the system, has led me to strongly advocate the use of electromagnetic instruments with gravity control for switchboard use whenever the conditions render them applicable, and I fully expect to see this type of instrument become more popular, as its advantages become more widely appreciated. Such a system is not applicable for portable instruments, save the dynamometer system for alternating currents, and even then a spring control must be used: nor is the series electromagnetic ammeter practical above about 1,500 amperes, due to the structural difficulties involved in carrying the 'bus bars directly to the instrument terminals. The one objection most commonly urged against the electromagnetic instrument for direct-current switchboard use is the unequally divided scale, for, as a rule, the scale only covers a range starting at 10 per cent. of the total up to maximum. In most cases, however, this objection is purely captious, for a switchboard voltmeter is seldom used to indicate more than 10 per cent. above or below the normal voltage, and the ammeter indications are of principal importance in the higher ranges to prevent a possible overload of the circuit or generator. In alternating-current circuits an equally divided scale is an impossibility, so why should we sacrifice constancy in direct-current measurements for the sake of an equally divided scale when the lower registers are so seldom used? In portable direct-current instruments the proposition is somewhat different, as we desire to cover the maximum limits of possible measurement on a single-scale instrument, therefore an equally divided scale is desirable and practically necessary.

Taking up now the different types of instruments which are in most common use, we find they may be roughly divided into six classes, depending on the principle by means of which measurements of voltage, current, or power are made; (1) the hot-wire; (2) the tangent galvanometer; (3) the electrostatic; (4) the dynamometer; (5) the D'Arsonval galvanometer, and (6) the electromagnetic.

The hot-wire instrument is designed to operate by the expansion of a fine wire or strip of conducting material due to the heating produced by the passage of the current to be measured, and, therefore, the indications are proportionate to the square of the current. This type of instrument possesses the advantage of indicating with equal accuracy the current flow on either direct or alternating current circuits, and is independent of the frequency of

* From the *Journal* of the Franklin Institute.

Digitized by Google

the circuit or of the shape of the current wave; it is further unaffected by the presence of external fields. These advantages, however, are all that can be claimed for this system, and to offset them are many serious disadvantages. Since the instrument operates by virtue of temperature differences, it is extremely susceptible to variations of external temperature, and such variations must be compensated either by mechanical means, which provide for bringing the pointer to zero by increasing or decreasing the tension on the working wire, or by providing auxiliary heating strips, which are supposed to automatically adjust the tension of the working wire on the general principles of a thermostat. This may seem a small matter to most observers, but to me it signifies an error in principle, and reminds me of one of our early types of arc dynamos which, by reason of incorrect construction, was found to spark badly; so, in place of correcting the design, an air blast was provided to blow out the spark. Another point of objection is the constant change of zero, due to the fact that until the wire has been stretched to its elastic limit it will fail to return to the same point after having been stretched by the heat applied, and will always show a slight residual strain. To attempt to correct this prior to installation in the instrument means, judging by my own experience, that at least 90 per cent. of the wires will break during the preliminary stretching process and the remaining 10 per cent. will stand but a very slight overload in service. As overloads are quite common, this would constitute a serious objection, for it means the return of the instrument to the manufacturer for the insertion of a new wire and recalibration. Another very serious objection is the amount of current required to operate the instrument. The average resistance of a modern hot-wire voltmeter is four ohms per volt, which means a current flow of ·25 ampere. This low resistance effectually bars this type of instrument for accurate testing, since the amount of power abstracted from the circuit to be tested vitiates the accuracy of the results obtained and introduces serious errors, which must be allowed for in all calculations. Recently an attempt has been made to introduce the hot-wire instrument as a shunt ammeter, particularly for alternating-current measurements. As a shunt ammeter, the hot-wire instrument is a distinct failure, for, while the manufacturers claim it can be operated on a drop of ·3 volt for full scale, my personal experience has shown a drop of six volts to be necessary. On the makers' figures, 300 watts would be required to operate a 1,000-ampere ammeter (nearly 4 h.p. per instrument), while on the sample I have tested 6,000 watts, or 8 h.p., would be required. Again, it has been shown that these ammeters when calibrated on direct current are not accurate within 10 per cent. when used on alternating currents, unless the reactance in the shunt is exactly equal to the reactance in the instrument, a condition almost impossible to obtain even with the most careful design.

A modification of the hot-wire system has been proposed, consisting of an enclosed chamber containing a fixed resistance wire, one end of the chamber, which is made airtight, consisting of a flexible diaphragm operating the pointer through a system of levers. In this case the heat supplied to the wire by the passing current causes the air in the enclosed cylinder to expand, and, consequently, puts the diaphragm under tension, very much on the principle employed in the aneroid barometer. I find by actual experiment that such a system could be applied to voltmeters, and could be so made that it would be accurate in its indications, and would possess a reasonably high resistance. The feature, however, which renders this system impracticable is the slowness with which the readings can be taken. The pointer will not come to rest until after the heat supplied the air enclosed within the chamber is equal to the heat radiated by the walls of the enclosing chamber, and from 1½ to 2 minutes are required before the pointer will come finally to rest at the part of the scale marked to indicate the impressed E.M.F. This is true no matter how small the air chamber is made, and while it is possible to shorten this time by carefully covering the sides and one end of the cylinder by a heat-insulating jacket, still it cannot be constructed so as to give an instantaneous reading, and every attempt to shorten the time by covering the walls of the chamber results in a corresponding increase of the time required for the pointer to come back to zero after current has been shut off. In other words, the instrument is similar in its action to an ordinary thermometer, which, as you know, cannot be made to respond instantly to changes of temperature.

Electrostatic instruments, which depend for their action on the mutual attraction of two plates connected to the opposite sides of the line, are still used, but not extensively, for high-tension measurements. They will indicate correctly on either direct or alternating current circuits, but are limited to measurement of voltage. It is impossible with this type of instrument to obtain a low reading, as the attraction of the plates toward one another varies approximately with the square of the potential difference between them. I say "varies approximately" advisedly, as the capacity of two plates varies directly with the square of the voltage only when the distance between the plates is maintained constant, which in this case is an obvious impossibility. As a rule, these instruments cannot be made dead-beat without introducing elements liable to seriously interfere with their accuracy; and while there are no errors due to temperature changes, and while they are also extremely efficient, requiring no current flow at all, they are affected very considerably by external influences, particularly by static charges, which are almost invariably present in power stations or dynamo rooms, and, as you probably know, it is practically impossible to provide a shield for static effects.

Instruments employing the principle of the tangent galvanometer are still employed, and for certain classes of measurements are extremely useful. They can be particularly recommended for use as ground detectors or differential voltmeters, where the actual value of the indicators is of small moment, the particular object being to show a balance of two opposing voltages or the presence of a ground by deflection. In this system the magnetised needle is suspended vertically, and is acted upon by two equally and oppositely wound solenoids; that is, the solenoids are wound with two wires in multiple and then cross-connected, so that we have two circuits equal in effect but opposite in action. I might say, in passing, that if the proper proportions of solenoids to magnetised needle are employed, and the length of the magnetised needle properly proportioned to its area, the tangent galvanometer instrument may be made extremely accurate and also quite permanent. Care must be taken, however, that under no conditions can the direction of the lines generated by the solenoids oppose the lines existing in the magnetised needle, otherwise the value of the calibration is almost instantly destroyed.

For measurements of alternating-current voltage, and also for the measurement of the watt output of any alternating-current source of energy, the dynamometer system, in one of its many modifications, is unquestionably the best type of instrument that can be used. This instrument indicates directly the mean effective voltage of the line to which it is connected, and is equally accurate for direct-current measurements, provided readings are taken with the direct current flowing through the instrument in one direction, then the direction of the current flow reversed and a second reading taken, the mean of the two readings being the correct value of the impressed E.M.F. This for the reason that the instrument is extremely susceptible to the influence of external fields. Further, the dynamometer type of instrument is only properly adapted for use in portable instruments. The fact that two readings are necessary on direct current prohibits its use as a switchboard instrument on direct-current circuits, and its delicacy, coupled with its field of low intensity and its susceptibility to error, due to the presence of iron in its immediate neighbourhood, whether used on direct or alternating current circuits, renders it impracticable as a switchboard instrument for alternating current circuits. As an ammeter it cannot be successfully employed for measurements above ·5 ampere, due to the difficulty of providing perfectly flexible contacts capable of carrying large currents. When you attempt to convey a current into a moving coil beyond the carrying capacity of a flexible conducting spring, recourse must be had to mercury contacts,

Digitized by Google

and a mercury contact should never be employed in a portable or enclosed type instrument. In the dynamometer instrument great care must be taken to have the moving coil as light as possible, and to render the instrument aperiodic, or dead-beat, an aluminium air-vane, moving in a partially enclosed chamber, must be employed. Manually operated brakes acting on the delicate moving system should be avoided, as their continued use results in a serious derangement of the moving parts.

Instruments based on the principle of the D'Arsonval galvanometer are very extensively used to-day for both switchboard and portable instruments on direct-current circuits; they can be calibrated so as to show an equally divided scale, and, if properly constructed, are an extremely efficient instrument. Further, they are very well adapted to the measurement of resistances and grounds. In the construction of this type of instrument the important factor is the permanency of the permanent magnet fields employed. It is essential, in the first place, that the proper grade and quality of steel shall be employed, which means a steel possessing high permeability and a high degree of retentivity; then this steel must be carefully worked within definite limiting temperatures and must be treated with great care and skill in the process of magnetising and ageing. Further than this, the moving coil should be extremely light and the whole system carefully shielded from the influence of external fields, and yet so shielded that the moving coil will not be robbed of an appreciable number of lines of force, due to the presence of the shielding iron. The greatest field for this type of instrument is in the measurement of heavy currents—that is, for currents of 1,000 amperes and upwards, due to the fact that it can be operated as a shunt instrument, requiring an extremely small drop of potential, full scale being obtained with a drop of from ·03 to ·05 volt. This means a relatively high efficiency, and, while the instrument does not possess all the advantages of a series ammeter, yet it is far easier to instal, and where a high degree of accuracy in current indications is not demanded, will be found very satisfactory in practice.

Further than this, the D'Arsonval instrument, which gives deflections directly proportionate to the current flow, lends itself readily to a large variety of measurements, such as determining resistances and measuring the drop of potential from which resistances and grounds may be readily computed. It is, however, a type of instrument which should be handled with great care, as rough handling or the presence of powerful external fields will permanently destroy the accuracy of its indications. Further, since it depends primarily for its continued accuracy of the maintenance of a field of uniform strength, as supplied by its permanent magnet field, instruments of this type should be frequently checked to ascertain whether the permanent magnets have maintained their initial strength.

A great deal might be said on the subject of the last type under consideration—namely, the electromagnetic system—for there are probably more variations in practical construction contained in this type than in all the other types put together; some are good, many very bad. It is, however, unfair to adopt the policy of certain engineers, who unqualifiedly condemn every electromagnetic instrument, solely and entirely on the grounds that they contain a moving mass of iron, which, in their opinion, must render the instrument subject to errors of lag and hysteresis. My practical experience with this type of instrument, covering a great many years, has taught me that it is perfectly possible to so construct an electromagnetic instrument containing a mass of moving iron that errors of lag and hysteresis. if they are present, are so small as to be negligible. In order to achieve this result, it is necessary first to proportion every part of the instrument with reference to all other parts; to carefully shield the instrument from the influence of external fields, and this by means of a shield that will not introduce errors due to its own retentivity. The iron employed should be very small and very light, and should be selected after careful test for purity and absence of retentivity. It should then be formed up with care, and so treated that oxidation is practically impossible. The field due to the actuating solenoid should likewise be carefully studied, and should be designed so that the moving iron will at no time be completely saturated, and yet of sufficient strength, in conjunction with the shield employed, as not to permit the indications of the instrument to be seriously influenced by external fields. In no case should two masses of iron be employed, as is common in some types of instruments, which depend on the repulsion of a moving vane by a fixed vane of similar polarity, both being energised by the actuating solenoid. It is almost impossible to free double-vane instruments from errors of lag or hysteresis, and there is a further tendency for the pointer to stand off zero, due to the residual magnetism mutually induced in the two vanes.

The fact that the instruments constructed on the electromagnetic principle contain no material subject to change or deterioration, coupled with the fact that they can be built solidly and substantially, and controlled by gravity in place of a spring or springs, renders them exceedingly reliable in practice. If their calibration is correct when first installed, there is no reason why the calibration should change with time.

In the above brief description of the most common types of indicating instruments, it may be noted that there is no one type which is universal—that is, adapted for switchboard and portable use for either direct or alternating current measurements. While we can very readily dispense with the hot-wire and electrostatic instruments, the other four types are essential for some class of measurement, and for any particular line of measurement the most suitable system should be selected. It is possible that some day a universal system may be found, but until that time the user must select from existing types the one which in principle seems most applicable, not only to the character of electrical energy to be measured, but also to the conditions under which measurement must be made.

(To be continued.)

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

303. Explain the use and working of the Kelvin earth-current recorder, with automatic short-circuiting switch. Give diagram of connections?—K. V. R.

304. What are the best and most useful forms of earth-plates used for lightning arresters?—F. H.

ANSWERS.

Question No. 295.—What is the best arrangement and the best machinery to use to run 14 direct-current arcs taking 25 amperes?

Best Answer to No. 295 (*awarded* 10*s.*).—If the lamps are situated close together for the purpose of lighting a single factory or other building, it would be best to run them either all in parallel off an ordinary compound dynamo wound for about 60 volts, or in seven parallel groups of two lamps each off a 110-volt or 120-volt generator. In either case, a steadying resistance should be placed in series with each lamp or pair of lamps. This arrangement will allow a standard and therefore cheap dynamo to be used, it obviates the use of a dangerously high voltage, and the same generator can be conveniently

Digitized by Google

used for incandescent lighting if any should be required. If, however, the 14 lamps are distributed over a considerable space, as in street-lighting or similar work, it will be distinctly more economical in copper to work them all in series at 700 to 750 volts. In this case the dynamo must be a series-wound arc lighter with a drooping characteristic curve, so as to ensure steady burning. The lamps need not have any special steadying resistances, but must be fitted with automatic cut-outs, so that in case of accident to one lamp it will be at once short-circuited, and the remaining lamps will continue to burn uninterruptedly. If lowness of price of the installation is the great object, the dynamo should be a high-speed belt-driven one, but if space is of more importance, a direct-coupled engine set would probably be preferable, though more expensive.—Q.

Answer to No. 295 *(awarded* 5*s.).*—The best way of running the arc lamps is by the series method. Compared with parallel running, the series system possesses many advantages, both as regards steady burning and first cost.

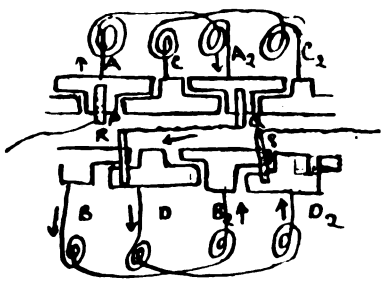

FIG. 1.

With parallel working for 14 arc lamps, each taking 25 amperes, we should require a generator capable of giving 350 amperes at 50 to 60 volts. This, in the first instance, is against parallel working; the quantity of copper in a system using such a large current would cost far more than a series system. Besides this disadvantage of first cost, the lamps are found to run very unsteadily, and require resistances to reduce the current, or a general burn-up in the lamp is the result. It will be seen from the above that everything points to series working when arc lamps only are to be used on the generator. The generator in a series system gives out a small current at a high voltage—in the case in question 25 amperes—and the voltage = (14 × volts required for each lamp); in addition, a small percentage must be allowed for drop in line. The lamps are all connected in series, and are provided with automatic cut-outs which cut out a faulty lamp. A disadvantage to this system is the high voltage used, which requires great carefulness in handling any apparatus, or fatal results may happen. The machines or generators used to generate the current are known as the open-coil type, the two best-known machines being the Brush arc lighter and the Thomson-Houston. The Brush machine is hardly so complicated in the armature winding as the

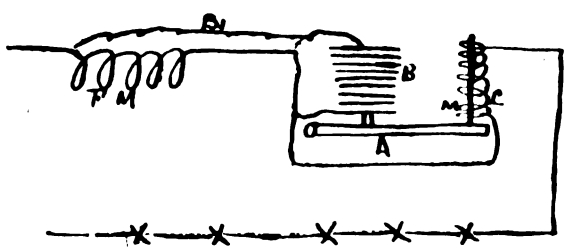

FIG. 2.

Thomson-Houston, and as this is a very important item, as the armature is generally damaged before any other part, I should advise the adoption of this type of machine. In a series machine the E.M.F. is taken from the coils at the moment of greatest activity—*i.e.*, when the E.M.F. is at its maximum. This leads to tremendous sparking at the brushes, but as no mica enters into the construction of these commutators, practically no damage is done. The coils are connected in pairs, and each pair is thrown out of the circuit when it is generating no current, and comes into the circuit again as the E.M.F. rises.

In Fig. 1 it will be seen that C C_2 are the pair of coils entirely cut out, whilst A A_2 are in the best position, and in series with these coils are B B_2, D D_2, four coils, which are rising to their best position. The commutator is in two parts, as shown, the brushes, R Q, being connected across, whilst P S feed outside circuit. The regulation of the current is accomplished by an ingenious regulator devised by Brush. When the current in outside circuit increases, the magnet core, C, is attracted, lifting the lever, A, and compressing carbon plates, B, thus enabling more current to go through B, and thereby weakening F M, the field magnets of the machine, and keeping the current steady. In starting a series machine, the current rises better if the terminals are shorted with fuse wire to allow the magnets to become excited.—F. M. M.

Answer to No. 295 (*awarded* 5*s.*).—As the number of lamps to be used is small, presumably only a small space is therefore covered. That being the case, an ordinary shunt-wound drum machine giving 100 volts (180 amperes) could be used as generator, the lamps being connected two in series across the mains. The lamps, if possible, should be arranged so that if any are cut out it will be two that are in series. If one of two in series is cut out, a compensating resistance must be put in to prevent injury to the remaining lamp. As an alternative to the above method, all the lamps can be connected in series and run from a series-wound generator giving 25 amperes at 720 volts. Any lamps cut out must be replaced by a compensating resistance, unless a special dynamo is used to keep the current constant, which is often done by shifting the position of the brushes by suitable mechanism.—F. H. PALMER.

Question No. 296.—In a continuous-current circuit, three-wire system, with 120 volts in the mains, which is the best way for supplying power in the daytime at 240 volts without any trouble, with the supply of light in the evening at 120 volts? It is needed that power cannot be used in the evening, nor the light in the daytime.

Best Answer to No. 296 (*awarded* 10*s.*).—The demand that it shall be impossible to use both the 240-volt motors and the 120-volt lamps at the same time distinguishes this from all ordinary three-wire systems. The required result can, however, be fairly simply obtained by means of the arrangement shown in Figs. 1 and 2.

The 120-volt lamps are connected between the middle and the outer wires as usual, the total number of lamps being divided as evenly as possible between the two sides of the system, so as to reduce the current in the middle wire to a minimum. The 240-volt motors, as will be seen by the figures, are connected between the middle wire and one of the outers, the same outer being used for all the

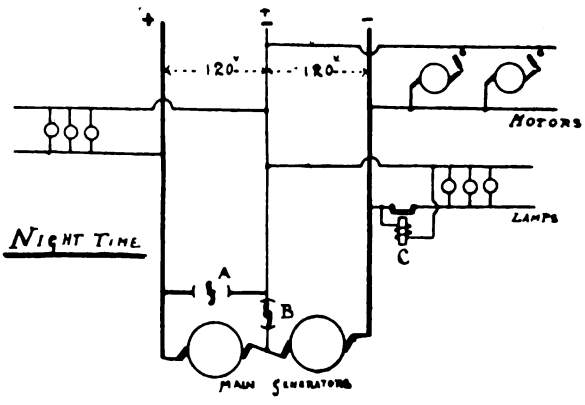

FIG. 1.

motor connections. The method of working the system is as follows: During the night-time, when lamps only are to be used, switch A will be open and switch B closed, as in Fig. 1, and the arrangement will be the ordinary three-wire system in every particular. During the daytime, when motors only are to be used, switch A will be closed and switch B open, as in Fig. 2, thus disconnecting the middle wire from the ± terminal of the main generators (or balancer if one is used) and connecting it directly to one of the outer wires (the outer to which no motors have been

Digitized by Google

connected), with the result that the volts across the left-hand side of the system (Fig. 2) are made zero, and the volts across the right-hand side, to which all the motors are connected, are raised to 240.

Now, with regard to the impossibility of running both lamps and motors at once. With the night-time connections (as shown in Fig. 1) it will be seen that the voltage across the motors is only 120, so that even if switched in they would run at a very slow speed, would take a very large current, and would consequently heat and spark, and thus effectually prevent any consumer continuing to run them. A more satisfactory arrangement, however, and one preventing any risk of damage to the motors, would be to have all motors fitted with automatic release starting switches, S, of the Cutler-Hammer pattern, which are now so commonly used. These would prevent the motors ever starting at all with 120 volts, as the switch handle would simply fly back to its "off" position as soon as the hand is removed. With the daytime connections (as shown in Fig. 2), the voltage over the lamps on

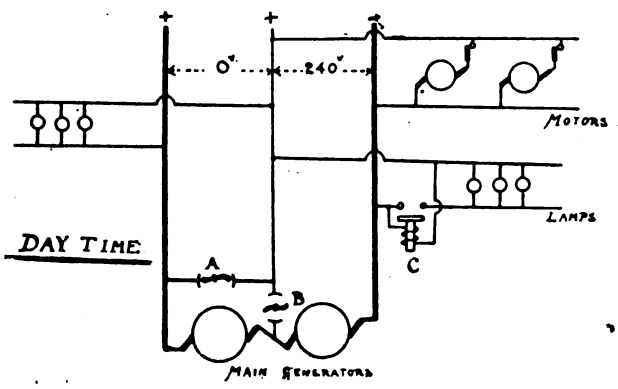

FIG. 2.

one side of the system is zero, so that they could not possibly be used, whilst the voltage on the other side would be 240, which would immediately burn out any lamps that might be switched in. In order to prevent this burning up of lamps it would probably be better to fit the lamp circuit in every house connected to that side of the system with a simple form of automatic cut-out, such as at C (Figs. 1 and 2), which would open the lamp circuit as soon as the voltage rose above 120. Failing such a cut-out, it would be necessary to close switch, A, slowly through a resistance, so as to give consumers who had left lamps on timely notice. With the arrangement described it will be noticed that the middle wire of the system must have sufficient section to carry the whole of the motor current. With the relation of out-of-balance current to motor current found in an average supply station, this would, however, not necessitate a larger middle wire than would anyway be put in.—Q.

Answer to No. 296 (*awarded* 5*s*).—This question has been so vaguely drafted that it is difficult to discover what

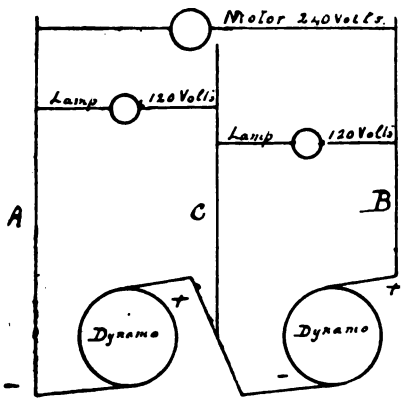

FIG. 1.

is required. The writer has assumed that it applies to a central station where the generating plant is too small to provide for both the lighting and power demands, and that it has been decided, since "it is needed that power cannot be used in the evening nor the light in the daytime," to supply current for power purposes only at 240 volts in the daytime, and for lighting purposes at 120 volts in the evening, and that now a simple and effective arrangement of switchboard and mains is required. If this be the correct interpretation, it is evident that the ordinary three-wire system, shown diagrammatically in Fig. 1, cannot be used where the motors would be coupled across the two outers, A and B, and the lights approximately equally between the outers and middle wire, AC and BC; for although by opening a switch placed between C and the

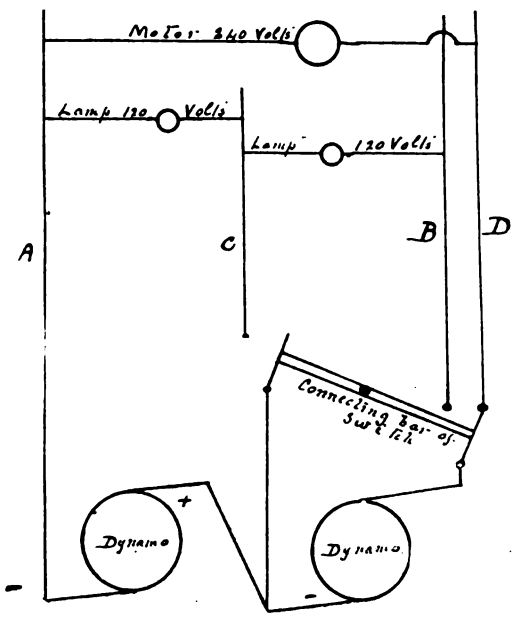

FIG. 2.

dynamo leads it would be easy to prevent the lights being used in the daytime, it would be impossible to prevent the motors being thrown into circuit in the evening. If, however, one of the outers, say B, were duplicated by an additional wire, D, the motors could be connected across from D to A, and the lighting circuits from B to C and C to A, while Fig. 2 shows an arrangement of one single-way switch fixed in C, and one two-way switch for D and B, and this is so arranged that if D be connected to the dynamo, the switch in C would be open, while if C be closed the same movement will cause D to be broken and B to be connected to the dynamo.—M.

Answer to No. 296 (*awarded* 5*s*.).—It is here assumed that the three-wire system mentioned is supplied at a pressure of 240 volts across the outers. If this supposition is correct, there is no reason why the motor supply at that pressure and the lighting supply at 120 volts should not go on at the same time, unless, of course, it so happens that the generators are not capable of a greater output than the motor load.

Fig. 1 is a diagram of connections for running both motors and lights at the same time. The motors are placed directly across the outer bars, and are supplied by two-wire circuits quite distinct from the lighting circuits at 240 volts. M and L are the motor and lighting circuits; G_1, G_2, and G_3 are generators. G_1 and G_2, giving a pressure of 120 volts, are coupled in series on either side of the neutral wire. During lighting hours they will act as balancers, in addition to maintaining a pressure of 240 volts across the outers. G_3, a generator giving a pressure of 240 volts, is shown connected directly across the outers. This is not really a necessary arrangement, as generators connected as G_1 and G_2 will do all that is required. C_1, C_2, C_3, and C_4 are automatic cut-outs set to open the circuits if the current passing through them should fall below a certain value; f_1, f_2, f_3, and f_4 are safety fuses; and s_1, s_2, and s_3 are the shunt field windings of the dynamos. If it is desired to so arrange matters that the lights and motors cannot be used at the same time, leads from the three bars can be brought to a triple-pole change-over switch, as shown in Fig. 2. When the switch is in the lighting position, the contacts, a_1 a_2, b_1 and b_2, c_1 and c_2, are bridged across by

Digitized by Google

the three blades with which the switch is provided. With the switch in the motor position, the contacts, a_3 and a_4, c_3 and c_4, are bridged across, and the lighting contacts opened so that the two sets of circuits can never be closed

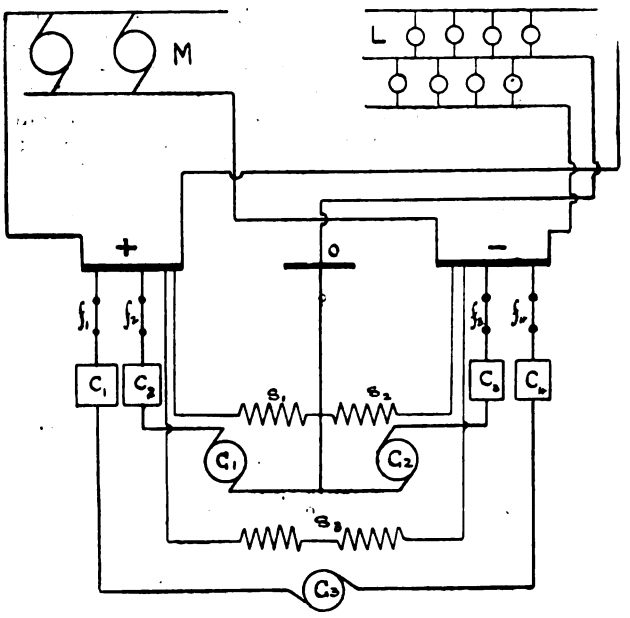

FIG. 1.

at the same time. The switch is shown in the off position. In connection with the blades is a powerful arrangement which ensures a quick break. This, however, does not

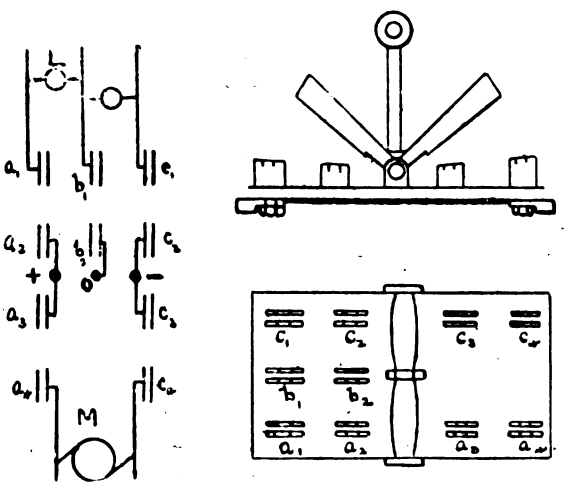

FIG. 2.

take place until the handle has been well pulled over, so that the operator's hand is quite clear before the switch opens.—P. S. T.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Lincoln.—The Town Council invite tenders for wattmeters and demand meters. Tenders by Sept. 14.

Hamburg.—Two 30-ton electric cranes are required. Enquiries may be made at the Town Hall. Tenders by Sept. 10.

Preston.—Tenders are invited for the electric lighting of the Preston and County of Lancaster Royal Infirmary. Tenders by Sept. 1.

Hampstead.—The Vestry invite tenders for various plant for their central station, Lithos-road, Finchley-road. Tenders by Sept. 27.

Piatra Neamtz (Roumania).—The Municipality invite tenders for the lighting of the town by electricity for 30 years by Nov. 2 (concession).

Plumstead.—The Vestry invite tenders for the supply and erection of various plant and machinery for electricity works. Tenders by Sept. 19.

Worthing.—The Corporation invite tenders for the construction of a new electric generating station and alterations of buildings at the Corporation yard.

Perth.—The Commissioners invite tenders for meters (direct-current) and cut-outs. Tenders by Sept. 15. Details in our advertisement columns.

Philippopolis (Bulgaria).—The Town Council invite tenders for erection and working of electric lighting and working of tramways. Tenders by Nov. 4 (concession).

Oldham.—The Electric Light Committee invite tenders for the supply, delivery, and erection of boilers. Tenders by Sept. 11. Full details in our advertisement columns.

Nelson.—The Corporation invite tenders for the supply of a 200-kw. steam dynamo for their electricity works. Tenders by Sept. 8. Details in our advertisement columns.

Southampton.—The Harbour Board invite tenders from crane builders for one 30cwt. portable electric wharf crane. Tenders by Sept. 10. Details in our advertisement columns.

Preston.—The Guardians invite tenders for an electric light installation at Fulwood Workhouse, near Preston. Tenders by Sept. 10. Details in our advertisement columns.

Leeds.—The Tramways Committee invite tenders for the erection of a new boiler-house (all trades except ironfounder) at the generating station, Crown Point. Tenders by Sept. 3.

Hammersmith.—The Vestry invite tenders for two single-phase alternate-current motors, coupled to two centrifugal pumps, with accessories. Tenders by Sept. 12. Full details in our advertisement columns.

Horton (Surrey).—The Asylums Committee of the London County Council invite tenders for the installation of boilers, engines, dynamos, etc., at the Horton Estate, Epsom, Surrey. Tenders by Sept. 22.

Cupar Fife.—Estimates are wanted for the electric lighting installation at the Fife and Kinross District Lunatic Asylum. About 800 lights. Tenders to Mr. Osborne, clerk to the Board, Cupar Fife, by Sept. 3.

Doncaster.—The Corporation invite tenders for the wiring and supply of sundry fittings for an installation of electric light at the Mansion House, Doncaster. Tenders by Sept. 5. Details in our advertisement columns.

Hull.—The Electric Lighting Committee invite tenders for steam and water pipes, feed pump, water softener, etc., at their Sculcoates-lane generating station. Tenders by Sept. 27. Full details in our advertisement columns.

Southampton.—The Guardians invite tenders for the erection and completion of electrical plant and installation for the lighting of the new workhouse infirmary, Shirley Warren. Tenders by Sept. 11. Details in our advertisement columns.

Tunbridge Wells.—The Corporation invite tenders for the supply and delivery of high and low tension cables. Specification and full particulars can be obtained from Mr. Horace Boot, borough electrical engineer. Tenders by Sept. 20.

Wrexham.—Tenders are invited for three electric motors and all accessories, working at 500 volts, to drive centrifugal pumps. Also one dynamo, capable of supplying energy for the above motors, together or singly. Details in our advertisement columns.

Greenock.—The Police Board invite tenders for traction plant as follows: water-tube boilers, two steam dynamos (high-speed enclosed engines), boosters, switchboard, steam and exhaust pipes, etc. Tenders by Sept. 10. Details in our advertisement columns.

Poplar.—The Managers of the Poplar and Stepney Sick Asylum District invite tenders from firms willing to perform sundry work in connection with the new telephonic installation at the sick asylum. Tenders by Sept. 10. Details in our advertisement columns.

Bradford.—The Corporation invite tenders for erection of an electric tramcar shed at Thornbury. Drawings, specification, and general conditions may be seen, and bill of quantities obtained, at the office of Mr. J. H. Cox, city surveyor, Town Hall. Tenders by Sept. 3.

Doncaster.—The Corporation invite tenders for the conversion of existing gas fittings and the supply of new fittings for the purpose of lighting with electricity the whole of the Mansion House, Doncaster. Tenders by Sept. 5. Details in our advertisement columns.

Hackney.—The Electric Lighting Committee invite tenders for condensing plant, cooling apparatus, pipework and valves, feed pumps, switchboard and boosters, public arc lamps meters, travelling crane, and workshop equipment. Tenders by Sept. 12. Full particulars in our advertisement columns.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of the following plant: lighting switchboard, traction switchboard, and balancing transformers at their new electricity works, Strawberry-road, Pendleton. Tenders by Sept. 3. Details in our advertisement columns.

Whitby.—The Council invite tenders for the following plant: two water tube boilers, pumps, condensers, pipes, etc., two steam dynamos, balancer, and boosters, switchboard and connections, battery, travelling crane and cables, arc lamps, etc. Tenders by Sept. 3. Details in our advertisement columns.

Aberdeen.—The Electric Lighting Committee invite tenders for supply of (1) two 200-kw. direct-coupled continuous-current generators and one 120-kw. balancing set; (2) one 420-kw. direct-coupled continuous-current generator. Specification and form of

Digitized by Google

tender can be obtained from Mr. J. Alex. Bell, city electrical engineer, Cotton-street, Aberdeen. Tenders by Sept. 29.

Walthamstow.—The Council invite tenders for the supply, delivery, and erection of electric lighting plant and apparatus, consisting of gas plant, gas-engines, dynamos, switchboard, booster, balancer, and measuring instruments. Tenders by Sept. 25. Details in our advertisement columns.

Portsmouth.—The Corporation invite tenders for the supply, delivery, and erection of the whole of the plant and apparatus necessary to completely equip for electric traction their proposed power station at Vivash-road, Fratton-grove, Portsmouth. Tenders by Sept. 4. Details in our advertisement columns.

Dundalk.—Tenders are invited by the Urban District Council for a transfer of their electric lighting order for the purpose of supplying electricity for public and private lighting and energy for manufacturing purposes within the urban district of Dundalk. Tenders by Sept. 18. Details in our advertisement columns.

London, E.C.—The Commissioners of H.M. Works and Public Buildings invite tenders for the enlargement of Block E of the telegraph factory at Mount Pleasant, E.C. Drawings, specification, and a copy of the conditions and form of contract may be seen on application to Mr. J. Wager, at H.M. Office of Works, etc. Tenders by Sept. 18.

Salford.—Tenders are invited for the supply and delivery of the following materials for the ensuing 12 months: high and low tension single and concentric cables, and house fuse-boxes, meters, and meter boards. Full particulars from Mr. F. A. Wilkinson, borough electrical engineer (pro tem.). Electricity Works, Walness-road, Salford. Tenders by Sept. 10.

Mexborough.—The Council invite tenders for the supply and erection of a Lancashire boiler; two 50 kw. steam dynamos, balancer and boosters, feed-water heater, and feed pump; switchboard and connections; storage battery; mains; a five-ton hand travelling crane; and for adapting public street lamps from gas to incandescent electric. Tenders by Sept. 15. Details in our advertisement columns.

Dublin.—The Electric Lighting Committee of the Corporation invite tenders for the supply and laying of electricity supply mains and accessories. Specifications and form of tender may be inspected at the office of the city engineer, Mr. Spencer Harty, M.I.C.E., City Hall, Dublin, and at the offices of Mr. R. Hammond, consulting engineer to the Corporation, 64, Victoria-street, S.W. Tenders by Oct. 4.

Worthing.—The Corporation invite tenders for the supply and erection of the following plant: (1) three 96-kw. steam dynamos (vertical enclosed high-speed engines); (2) two boilers of the dry-back marine type, with fittings, etc.; (3) steam and exhaust, drain and other pipes, in engine and boiler house, pumps, condensing plant, etc.; (4) cast-iron manhole covers; (5) cast-iron arc lamp posts; (6) stoneware casings; (7) cable work; (8) arc lamps; (9) storage batteries; (11) balancing transformers and motor-generators; (12) economiser; (13) five-ton overhead engine-room travelling crane. Tenders by Sept. 3.

Fenton (Staffs).—Tenders are invited for works in connection with the construction of a single line of railway (2ft. 6in. gauge) from Waterhouses to Hulme End, Staffordshire (about eight miles two furlongs), and incidental works connected therewith, for the Leek and Manifold Valley Light Railway Company. Plans, specifications, bills of quantities, and forms of tender may be inspected at the offices of the company's engineer, Mr. Joseph Forsyth, Heron's Cross, Fenton, Staffs, on and after Aug. 4, and copies of same may be obtained from him. Sealed tenders must be sent to Mr. Edward Challinor, secretary, Leek, by Sept. 1.

RESULTS OF TENDERS.

Wimbledon.—The Electric Lighting Committee have accepted the tender of Messrs. J. Dorking and Sons (£73) for the erection of a temporary shed for engine-room extensions.

Souleoates.—The Works Committee of the Guardians have accepted the tender of Mr. J. Morley, for electric wiring and fitting the Beeton street relief office, at £24. 15s. 6d.

Radcliffe.—The Nottinghamshire County Council have accepted Mr. Scott Anderson's tender and scheme for the lighting of the new county asylum at Radcliffe. It comprises engines, dynamos, and the complete electrical and steam equipment for the asylum.

Ashington.—The Ashington Industrial Co-operative Society, Limited, have received the following tenders for the electrical lighting and heating by hot water of their business premises in New Hirst:

Electric light.

Gateshead Electric Supply Company, West-street, Gateshead-on-Tyne (accepted)	£395
Carrick and Stevenson, Newcastle-on-Tyne	310
Bland Bros., Barras Bridge, Newcastle-on-Tyne	398
T. G Usher and Co., Newcastle on-Tyne	420
T. S. Brown, Newcastle on-Tyne	425
Corlett Engineering Company, Newcastle-on Tyne	430

Heating apparatus.

Dinning and Cooke Newcastle-on-Tyne (accepted)	107
Emley and Sons, Newcastle-on-Tyne	112
Bland Bros.	120
T. S. Brown	160
T. S. Vaux and Sons, Newcastle-on-Tyne	75

Epsom.—The London County Council have accepted the tender of Mr. T. Scott Anderson, electrical engineer, Sheffield, for the electrical equipment of the asylum at Horton, Epsom.

Shoreditch.—The Vestry have received the following tenders for electric cable:

Siemens Bros. and Co., Limited	£2 262 8 4
W. T. Henley's Telegraph Works Company, Limited	2,147 15 1
W. T. Glover and Co., Limited	2,129 12 6
British Insulated Wire Company, Limited	1,930 8 2

BUSINESS NOTES.

LIGHTING AND GENERAL.

Keighley.—Sanction has been obtained to the loan for electricity works.

Nuneaton.—We understand that the Urban District Council are about to supply electric light to the New Theatre Royal.

Eastern Cables.—The telegraph steamer "Pender" left Shanghai on Aug. 29 to lay a cable between Wusung and Chefoo.

Maryport.—Applications for a supply are already coming in before the Council have settled the preliminaries in connection with the electric lighting.

Penny-in-the-Slot Telephones.—The General Post Office authorities are introducing coin-receivers in connection with the new telephone system for London.

Wimbledon.—The surveyor has been instructed to forthwith prepare the foundations for the new engines, and remove the end gable wall of the electricity works.

Fleetwood.—The Fleetwood and District Electric Light Company now destroy the whole of the town's refuse, so that the objectionable refuse tips are now things of the past.

Aberdare Electric Lighting Co., Limited.—This Company has been registered, with a capital of £2,000 in £1 shares, to carry on the business of an electric light company in all its branches.

Darlington.—Owing to the slow delivery of the engine and machinery for the power station, it is doubtful whether the electric light will be inaugurated at the beginning of October, as anticipated.

Finchley Electric Light Co.—This Company has been registered with a capital of £3,000 in £1 shares, the object being to carry on at Finchley or elsewhere the business of an electric light company in all its branches.

Telephone Novelties.—Several new telephone inventions having been recently patented in the United States, the general manager of the National Telephone Company has sailed for New York in search of novelties for the London service.

Goole.—At the meeting of the Rural District Council on Monday a resolution was carried unanimously that the clerk should at once take steps to apply for a provisional order, and that the clerk notify the Northern Electric Light Installation Syndicate to that effect.

French Prices.—In consequence of the rise in prices of materials, the manufacturers of electrical fittings in France recently raised their prices of meters 15 per cent., those of copper work 15, ironwork 35, rubber 15, electric cables 25, and joints, etc., 15 per cent.

Wycombe.—The whole of the 1,000 £5 shares offered to the public by the Wycombe (Borough) Electric Light Company, as additional capital, have been taken up. We learn that a large proportion of the applications came from the town and neighbourhood of Wycombe.

Maidstone.—It is reported that the Local Government Board have notified the town clerk that while they are virtually prepared to approve the scheme of electric lighting for the borough, they would like to have the opinion of an independent expert with regard to the same.

Liverpool.—On Wednesday the successful inauguration of the electric light to the wholesale fish market took place. The gas jets have been replaced by 20 arc lamps, which impart infinitely more candle-power than could ever have been dreamt of under the old system of gas lighting.

Paris Exhibition Awards.—Messrs. Salviati, Jesurum, and Co., Limited, London and Venice, have been awarded at the Universal Exhibition, Paris, the following: grand prize for lace, grand prize for glass, grand prize for mosaics, and gold medal for electrical chandeliers and other fittings.

Crieff.—In consequence of the intended application of the North British Electricity Supply Company for a provisional order to supply the town with electric light, the Town Council in committee have agreed that they themselves should apply to Parliament for such provisional order.

Bury St. Edmunds.—The inaugural supply from the borough's electric lighting works was switched on about sunset on Tuesday, the lamps being principally in private houses. As soon as the work of erecting arc lamps has been completed the principal thoroughfares of the borough will also be lighted.

Stirling.—Four tenders have been received for the work in connection with the electric lighting of the old burgh buildings,

Digitized by Google

Broad-street, St. John-street, and police and Parish Council offices and night shelter, excluding the police court-room. The estimate was £60. The tenders have been remitted to the electric lighting engineer.

Kidderminster.—The electric tramway company has combined lighting with traction. In the presence of the Mayor the first public electric light was switched on on the 22nd inst. Mr. J. B. Clarke, the resident engineer to the tramway company (late of the Electric Construction Company, Bushbury), is assisting with the lighting of the town.

Rathmines.—The postponed opening of the electricity works by their Excellencies the Lord Lieutenant, K.G., and the Countess Cadogan, will take place to-day at 3 p.m. After the opening ceremony a reception will be held by Mrs. Hodgson, on behalf of the Council, in the grounds of the Leinster Cricket Club (adjoining the electricity works).

Wrexham.—At Tuesday's meeting of the Town Council the engineer presented a satisfactory report upon the progress of the electric lighting of the town. It was decided to extend the distributing main into Egerton-street. The Council adopted 6d. per unit as the price of the current for lighting purposes and 3d. per unit for motor purposes.

Bury (Lancs.).—Business in the new post office buildings in Crompton-street was commenced on Monday morning. Although gas fittings have been provided, the building will be lighted throughout by electricity, for which purpose an installation of 122 lamps, principally of 16 c.p., has been put in by Messrs. Crowther and Co., of Manchester and Liverpool.

London Gazette.—Receiving orders have been made out *re* R. Foster and Co. (also trading as the Nelson Electrical Engineering Company), Adlington-street, Nelson, Lancs., and F. L. Lindsay, 216, High-street, Bangor, both on creditor's petition. The estate of W. Dalzell, 13, Forsyth-road, West Jesmond, Newcastle-on-Tyne, has been released from trusteeship.

Burnley.—The Guardians intend to apply for sanction to borrow £3,000 to defray the cost of an electric light installation at the workhouse, and the erection of a new boiler-house and the provision of two new boilers. Messrs. Shepherd and Watney are to carry out the necessary works in connection with the proposed electric light installation, and Messrs. Keighley will be engaged as architects in connection with the erection of boiler-house and other buildings.

British Thomson-Houston Co.—We have received from this Company their pamphlet No. 69, which deals with electric traction. The pamphlet gives practically a history of the development of electric traction, and more particularly of the British Thomson-Houston system. At the end of the article is a table containing a list with particulars of the tramways and railways in the United Kingdom which are equipped, or about to be equipped, with apparatus manufactured by the above Company.

Stock Exchange.—The Stock Exchange Committee have appointed Thursday, Sept. 13, a special settling day in Potteries Electric Traction Company, Limited, £125,000 4½ per cent. debenture stock; and have ordered the undermentioned securities to be quoted in the official list: Edmundson's Electricity Corporation, Limited, further issue of 9,400 ordinary shares of £5 each, fully paid, Nos. 17,401 to 17,407, and 26,108 to 35,500; and Potteries Electric Traction Company, Limited, £125,000 4½ per cent. debenture stock.

Llandudno.—The Electric Lighting Committee last week reported to the Urban District Council that they had been advised by Mr. Rooke, the representative of Mr. A. H. Preece, electrical engineer to the Council, to extend the condenser at the works to cope with the increased requirements. The cost was estimated at £1,500. The committee recommended the Council to make the proposed extension, and to instruct Mr. Preece to prepare plans and specifications, and obtain quotations for the work previous to application being made to the Local Government Board for sanction to obtain a loan to defray the cost.

Chiswick.—Great progress is being made with the electric lighting works of the district which have been carried out during the last two months by the Aberystwyth and Chiswick Electricity Supply Corporation, Limited. Consumers are coming on the system rapidly, and we understand that the new offices of the Urban District Council and the large assembly-rooms attached are to be supplied as soon as completed. The station is situated next to Messrs. Thornycroft's shipbuilding yard, on the banks of the Thames, and is rapidly approaching completion.

Hanley.—The Town Council have accepted a number of tenders for works required in connection with the electricity department to meet the increased demands made upon it, and application is to be made for sanction to borrow a further sum of £7,000. From January to July 473,000 units have been generated, while the output amounted to 311,000 units only. The committee are naturally anxious to find out where the leakage is. With regard to domestic lighting, it has been found that the consumption in many cases had been so small that the meters would not register it. This, however, they hoped to be able to remedy.

Bath.—At Wednesday's meeting of the Electric Light Committee it was decided to lay cables, at a cost of £370, in the Sion and Lansdown roads. The price of current from June 30 was considered, the electrical engineer (Mr. Metzger) saying the extra worked out at ½d. per unit. The question was whether they would make private consumers pay the whole, or charge part to public lamps. Adoption of the former course would mean an increased cost of nearly 1d. per unit. It was agreed to make the increased cost ½d. per unit for private and public lighting. The Chairman said work in connection with the electric light extensions was going on by leaps and bounds.

Fire.—An outbreak occurred on Wednesday in the Telephone Company's wire subway at the Embankment end of Northumberland-avenue, London. Large volumes of smoke arose from the manhole. Five of the six telephone linesmen who had descended for the purpose of examining and repairing wires made good their escape at the point of entrance. Another who was working further along the subway escaped by another exit. In the interim the company had been apprised of the outbreak, all currents passing along the circuits within the area were turned off, and in the course of half an hour the subway was again accessible and practically clear for the resumption of work.

Halifax.—Three new tramlines were passed here on Wednesday by Mr. A. P. Trotter, of the Board of Trade, and opened for traffic. The lines comprise the extension from King Cross to Cote Hill; a connection link, *viâ* Warley-road, between the King Cross and the Highroad Well routes; and an extension of the Illingworth branch to Causeway Foot. This latter line, from its commencement in the centre of the borough, is about four miles long, and has its terminus near to Ogden reservoir, a popular resort. About 15 miles of tramway belonging to the Corporation are now open for traffic. The extension of the Booth Town route to Queensbury, and the continuation of the Cote Hill branch to Hebden Bridge, will be undertaken shortly.

Appointments Vacant.—The Gas and Electric Committee of the Belfast Corporation invite applications for the post of an assistant electrical engineer, at a salary of £120 per annum.—The Commissioners of Partick require the services of a resident electrical engineer. Full particulars of these vacancies appear in our advertisement columns.—The Corporation of Eccles require the services of a borough electrical engineer, at a commencing salary of £200 per annum. Applications, stating age, endorsed "Borough Electrical Engineer," and accompanied by copies of not more than three recent testimonials, must be addressed to the Public Lighting and Electricity Supply Committee, and delivered at the office of Mr. Henry Hickson, town clerk, Town Hall, Eccles, by noon on Sept. 3.

Glasgow.—The Tramway Committee of Glasgow Corporation on Tuesday inspected the power station in course of construction at Pinkston, Port-Dundas, for the supply of electricity for the electric cars. According to a report in the *Scotsman*, Mr. Parshall, the consulting engineer, showed them over the buildings, and explained the machinery and its arrangements. There were two special cars of different designs submitted for the consideration of the committee, with the result that the present double-decker now on the Mitchell-street-Springburn route was formally selected as the most suitable for the new system over the whole city. Two very fine horse cars reconstructed to electric traction were also exhibited. At the car-sheds at Coplawhill new cars are at present being turned out at the rate of five every week. Mr. Young, the manager, believes that the electric system, embracing the entire city, will be inaugurated about the beginning of April next year, just on the eve of the exhibition.

Insulating Materials.—Amongst the numerous exhibits at the Paris Exhibition is that of Mr. H. Weidmann, of Rapperswyl, Switzerland. The exhibit consists of compressed pasteboard and other subjects which are used for insulating purposes. The works were originally intended for the manufacture only of glazed cardboard, but owing to the substance being found of use for electrical insulation purposes, Mr. Weidmann began to manufacture it especially with that view. A particular brand of insulating pasteboard is made with a very carefully-prepared surface. For this quality it is claimed that a thickness of about ·004in. will resist an alternating current of 3,000 volts. The compressed cardboard is usually supplied in sheets of about 3ft. square, but can be obtained in long rolls if desired. Micanised cardboard with layers of mica outside are exhibited, and also a number of small articles illustrating the use of asbestos hardened by a special process, which keeps its elasticity under practically all conditions. Other insulating substances are shown, amongst which are Japanese paper, or waterproof felt, friction rolls, by which the speed of small motors can be regulated, etc.

Aron Electricity Meter Co.—The exhibit of this Company at the Paris Exhibition consists of a meter for registering charge and discharge of accumulators, which adds 10 per cent. automatically at charge for the efficiency of the battery, reading direct in ampere-hours, at a constant-potential circuit of 230 volts, arranged for a battery of 50 amperes maximum discharge and 500 ampere-hours capacity; a direct-current 30 ampere 440 volt meter; an ampere-hour meter for accumulator use; a prepayment hour meter arranged for a tension of 220 volts direct current, adjusted for 6d. per Board of Trade unit for 2 c.p. lamps at 220 volts with 6d. in the slot; an hour-meter, recording the hours which a circuit is closed; a day and night load meter, 15 amperes, 110 volts, adjusted so that during the peak of load consumers may be charged a higher price than during the rest of the day; an alternating-current single-phase 30-ampere 100-volt type as approved by the Board of Trade, and as usually supplied for use in consumers' houses; an alternating-current single-phase meter for switchboard work for central-station purposes; and a lamp battery on slate with brass letters indicating the words "Aron Meter," on which letters are mounted lamps. The Aron instrument is stated to be equally applicable for continuous two-wire, three-wire, and five-wire, alternating-current single-phase two-wire and three wire, and two and three phase methods of distribution. It is interesting to note that all the meters on exhibition were constructed in the company's English factory.

Digitized by Google

Stockport.—We are informed by Messrs. Robert Dawson and Co., Limited, Stalybridge, that they were the contractors for the electric light installation at the Theatre Royal, the firm having been referred to by our correspondent as Messrs. Robert Dawson and Sons in our last issue. They also state that the rotary transformer referred to has been provided purely for the purpose of running stage arcs only.

St. George's, Hanover-square.—The Vestry have rescinded their resolution adopting the electric light as the illuminant for the streets in the parish. This step has been taken not because the members are opposed to electric lighting, but there is a feeling that the present time is inopportune for the introduction of the scheme, and that it is more advisable to wait until the borough council has been elected.

British Westinghouse Co.—We have received from the British Westinghouse Company a copy of a pamphlet entitled "Drop in Alternating-Current Lines," written by R. D. Merson. The matter appeared as an article in the *American Electrician*, and it goes very fully into the subject of loss of voltage. The reprint is naturally used as an introduction to the Westinghouse type of compensator, for which it is claimed that it will indicate the voltage at the load whatever may be the current strength or the character of the load. It is also capable of adjustment for circuits of different ohmic loss and different reactance. Diagrams of connections for compensators in single and three-phase circuits are shown in the pamphlet.

Dumfries.—Several companies have offered to take over the provisional order obtained by the Town Council for supplying the town with electricity both for lighting and motive power on very similar terms. The price demanded works out as follows: All electric current required for street-lighting, or for lighting the public buildings, to be supplied to the Council at the special rate of 7d. per unit for the first hour and 2d. per unit afterwards. For all-night street-lighting this will work out at 2½d. per unit. Prices to be charged to private consumers not to exceed 7d. per unit for the first hour and 4d. per unit afterwards. The Council to have the option of repurchasing the undertaking within 12 months after the expiration of 10 years.

Scunthorpe.—The electric light was formally switched on at the new Wesleyan chapel last week. The installation, which has cost about £500, was put down by Messrs. J. Dewhurst and Son, Sheffield. A dynamo giving 100 volts at 45 amperes is worked by an oil-engine of about 8 h.p., accumulators also being employed. One day's running of the engine will produce sufficient supply for a week. There are 111 incandescent lights in the building, the chief light coming from two handsome candelabra suspended from the ceiling, consisting of 25 lights each on six brackets, five four-lights, and one four-light. The lights in the centre are of 8 c.p., and those round the building of 16 c.p. The light is very satisfactory, burning quite steadily without being too brilliant; not hurtful, but restful for the eye.

Dublin.—At a recent meeting of the South Dublin District Council a letter was read from the Dublin United Tramway Company referring to the application of the Council *re* the proposed lighting by electricity of Templeogue and Rathfarnham. In this connection it was mentioned that it would not only be an advantage for the public to have these districts lighted by electricity, but it would enable the inhabitants to avail themselves of lighting their premises by electricity. The charge for gas was excessive. They paid 4s. 6d. per thousand cubic feet, and the quality was not the best. The smell of it was terrible. The Dublin Corporation on Monday decided, by a majority of 38 to 14, to carry out the electric lighting of the city as a municipal concern, instead of accepting the proposals of the electric tramway company.

Torquay.—An enquiry was held last week into the application of the Council to borrow £15 000 for electric lighting extensions. The Town Clerk stated that while at the end of March, 1898, there were 55 consumers, on March 31 they had increased to 221. The total equivalent number of 8-c.p. lamps connected in March, 1898, was 5,688, of which 3,310 were private lamps, and in March last there were 10,070 lamps. The total revenue for the first year was £2,837, and £3,699 for the last year. There was a gross profit of £1,057 on the first year's working, and of £1,256 on the second year's. The interest and sinking fund in each year was £1,188. There was thus a deficit of £138 on the first year, and a profit of £67 on the second. They had now some applications which they could not comply with. The borough electrical engineer (Mr. P. Storey) explained the details of the work proposed.

Yeadon.—The *plébiscite* taken on the electric lighting question cannot be described as satisfactory. Of the 890 papers distributed only 570 were returned to the collectors, and of this number 337 were blank, whilst of the remaining 173 papers 98 were in favour of the adoption of the electric lighting and 75 against. The 98 also promised to take 365 lights at a charge of 5d. per unit, or 304 if the charge was 6d. This number includes 100 from one person. At a meeting of the District Council on Friday night a motion to call a town's meeting was negatived, as was also a proposal that the Council recommend that the provisional order be transferred to a syndicate, provided reasonable terms could be arranged. The question is, therefore, at a deadlock. The period of grace allowed by the Board of Trade for the Council to take steps to carry out their order expires at the end of October.

Aberdeen.—The Corporation electric light accounts for the year ended July 31 last have been issued, and show from the revenue and expenditure account that, while the total revenue was £14,211. 3s. 10d., the expenditure amounted to £6,062. 0s. 10d., leaving a balance of £8,149. 3s. to be carried to net revenue account. From this, £2,343. 15s. 11d. was paid as interest on mortgages and other loans, £2,438. 15s. 4d. for depreciation, £1,336 to sinking fund, and £2,487. 18s. 11d. of a balance is carried to the reserve fund, which now stands at £2,609. 17s. The general balance fund stands at £100,727. 8s. 1d. During the year 1,005,505 Board of Trade units of electricity were generated and sold, as against 279 950 in 1899, but that was for seven months only. There are 76 public arc lamps and 80 incandescent. The amount of capital authorised to be borrowed is £82,000, and this has been exercised on mortgage to the extent of £81,953.

Personal.—We learn that Mr. H. F. Street, the Halifax electrical engineer, who was to have gone to Bolton, has decided to remain in Halifax, after having representations made to him by members of the Corporation.—The Bolton committee have appointed Mr. Arthur A. Day, A.K.C., A.M.I E E, of Manchester, chief assistant engineer Manchester Corporation electric works, to the post of borough electrical engineer. It is also proposed to present Mr. Ellis, the retiring engineer, with an honorarium of £200 for services rendered.—The appointment of Mr. Ernest Marples, chief assistant to the Liverpool Electric Lighting Company, as resident electrical engineer to the Hoylake and West Kirby Council has been confirmed.—On the 30th inst. the wedding took place, at St. James's Church, Muswell Hill, of Miss Pattie Klein and Mr. J. H. Heathman, the patentee and manufacturer of telescopic ladders and fire extinguishing appliances known under that name.

Gloucester.—At a meeting of the City Council held on Tuesday Mr. C. H. Clutterbuck, chairman of the Electricity Supply Committee, said they had received several applications from citizens to extend the system of arc lighting. The committee were making enquiries, and at the right time they hoped to extend the lighting in a direction where they knew it would not only be appreciated, but be profitable. The resident engineer (Mr. Bache) had furnished him with an up-to-date statement of their position with regard to the lighting, which was as follows: public street-lighting (equivalent in 8-c.p. lamps), 730; total number of lamps connected, 9 230; number of lamps being wired, and for which final applications have been received, 1,960; number of lamps for which preliminary applications have been received, 2,134—total, 14 058. It would, continued Mr. Clutterbuck, be remembered that Mr. Hammond reported on Aug. 29, 1899, that it would be permissible to instal on their mains 12,000 8-c.p. lamps. A short discussion followed, the speakers being unanimously in favour of the extension of the electric lighting into the Barton district.

TRACTION.

Bradford.—The Tramways Committee have decided to extend the new Westgate tramway to the corner of Godwin-street, a distance of about 150 yards.

Bilston.—The British Electric Traction Company have arranged to run a number of large two-horse omnibuses until the lines for the new electric tramways are in working order, for which they now have the Local Government Board's sanction.

Maryport.—Representatives of the Urban District Council will attend the conference (referred to in our last issue) with reference to Messrs. Dick, Kerr, and Co.'s proposal to obtain a provisional order to construct an electric tramway between Whitehaven and Maryport.

Wrexham.—At Tuesday's meeting of the Council, the Mayor announced that the Drake and Gorham Electric Company had taken over the old Wrexham Tramway Company's undertaking, and that there was now a prospect of there soon being electric trams in the town.

Motors.—Furious driving on the part of Paris automobilists is to be punished in future by imprisonment. The British Consul in Rome, Mr. C. Morgan, after referring to the increasing number of motorcars in the Italian capital in 1899, says that these are all of Continental manufacture, and thinks that the superiority of the British machine would secure patronage.

Paisley.—The tramways question is again to be discussed shortly at a ratepayers' meeting. We also learn that a petition from residents in Paisley and at the Glen has been forwarded to Mr. Murphy, expressing approval of the system of tramways proposed by him for Paisley and district, and requesting him to bring forward his Bill in the next session of Parliament.

Darwen.—At a public meeting of the householders of Hoddlesden, Blacksnape, Waterside, and Pickup Bank, held on Thursday week in the Co-operative Hall, Hoddlesden, resolutions were passed to urge upon the Darwen Town Council the advisability and the necessity of running trams to Hoddlesden, so as to bring Hoddlesden and the surrounding districts more into touch with Darwen.

South Lancashire Tramways.—Notification was received on Thursday week by the authorities affected from the South Lancashire Tramways Company stating that they intend asking Parliament next session for powers to extend their electric tramways from Worsley, through Little Hulton, to Farnworth, Little Lever, Radcliffe, and Whitefield—nearly 10 miles. This is in addition to a 70 miles network of tramways which the company are about to lay down in South Lancashire.

New York.—The first electrically-equipped train on the Manhattan Elevated Railway, New York City, will, according to the *Scientific American*, probably run on Sept. 15. The engines and generators are being rapidly completed. A trial train is nearly finished, and by next summer it is thought that the steam locomotives will be entirely dispensed with. The Second-avenue Railroad will be the first line to be equipped electrically. The total cost of making the change is said to be 12,000,000dol.

Digitized by Google

Preston.—The Streets and Buildings Committee of the Preston Town Council have decided to recommend the Council to undertake the working of an extensive scheme of electric tramways, powers to carry out which were obtained by an Act promoted by the Corporation this year. At present the cars are worked by horses, the system being leased to a company, whose powers expire in 1902.

Brierfield.—The District Council on Tuesday passed a resolution agreeing to purchase the tramways within their own district, and the decision was in every respect similar to that which was arrived at by the Nelson Corporation last week. Burnley and then Padiham, now Nelson and Brierfield, have agreed to purchase the various lengths of tramway within their own respective districts. Thus another stage has been passed in the scheme for acquiring and municipalising the Burnley and district tramways.

Overcrowding.—Mr. S. J. Wilde, who presided over the ordinary meeting of the South London Tramways Company, on Friday, said he regretted that two of their conductors had been fined the previous day for having an excess of passengers in the workmen's early trams. This was manifestly unfair, for no one could prevent these men forcing their way in, and if the conductor tried to stop them they would simply fight him. He maintained that this overcrowding could only be prevented by the police themselves. We quite concur; the police not only could, but should, prevent the unseemly rush and the ensuing overcrowding of both tramways and railways.

Nottingham.—Satisfactory progress is now being made with the works in connection with the Nottingham tramway undertaking. The track commencing at Sherwood is now practically completed as far as the Mechanics' Hall. Work has also commenced in Parliament-street. No definite decision has yet been arrived at as to when the work in the Great Market-place will be started, but in all probability this will be before Goose Fair. It is expected that the next section of the undertaking which will be commenced is to be the Bulwell one. The operations will begin at Bulwell Market-place, and the present route to the Great Market-place will be retained.

Sheffield.—In a note last week we referred to the intended tramcar improvements. The dry-seat to be tried by the committee is non-corroeive wire netting, about ⅜in. thick, which is laid on the top of the seat. The wire netting is covered with an amalgam of non-corrosive metal, so that it will not stain or damage the most delicate fabric. It can be attached to any existing seat at a small cost. The chief disadvantage of the patent would be in the case of snow. Another experiment is also to be made in order, if possible, to secure better ventilation of the cars, and a ventilator designed by Messrs. Turton, Platts, and Co., Sheffield, is to be affixed to a number of trams running on the different sections.

South Hams Light Railway.—At the Totnes Town Council on Monday, it was reported that the application of the promoters of the Devon South Hams light railway had failed, owing to the necessary formalities not having been complied with. A letter was read from Mr. T. W. Barber, engineer of the company, stating that it was remarked at the last enquiry that he had been requested by the Town Council to attend and discuss the matter, and that he had not done so. No invitation of the kind reached him, or he should have attended. As the promoter intended applying again in November, he should be glad to attend by appointment to arrange any matters of difference. The Council decided to wait until formal notices were given.

Durham.—The county of Durham is to witness an important development of the tramway service during the next two or three years. The company which is promoting the scheme is a large and influential one, and their intention is to connect the large and important mining centres by a service of electric cars. Thus tramways will be run from Easington-lane, through the Hettons, to Houghton-le-Spring, thence by way of Newbottle, Philadelphia, Shiney Row, New Herrington, Silksworth, Tunstall to Sunderland, where they will strike the borough boundary at Silksworth-road. An important branch of the several branches to be eventually laid down is that from Houghton-le-Spring to Fence Houses Station, and from Shiney Row to Penshaw Station. Naturally, some time will elapse before all this is an accomplished fact, but it is a sign of the times that the scheme has just received the Royal assent.

Blackpool.—Recently the employés on the promenade tramway memorialised the Corporation as to increased rates of pay, etc. Mr. J. Lancaster reported to the Tramways Committee on Tuesday that he had made enquiries from 21 tramway undertakings connected with municipalities in various parts of the country. As the result, he found that the wages and the conditions of employment at Blackpool were certainly as good as prevailed anywhere else, and that they were better than most places. Glasgow, which came out at about the top of the list, employed its tram-men for 10 hours a day at wages varying from 24s. to 28s. per week, but the maximum was not reached until a man had worked under the Glasgow Corporation for seven years. In Blackpool all drivers and guards receive 24s. per week as the minimum, while good men reached the maximum of 28s. per week after about two years' service. Then the longest hours worked by the Blackpool employés do not average more than 60 hours and 20 minutes per week. Replying to other points in the memorial, Mr. Lancaster stated that he had always observed the rule of promotion by merit, but, of course, it was impossible to allow the men to say who should or who should not be promoted.

Seaforth Junction.—Negotiations are, it is understood, proceeding with the Lancashire and Yorkshire and the Liverpool Overhead Electric Railway Companies touching the carrying out of the Seaforth junction scheme, for which the electric company recently obtained parliamentary powers. The position needs a little explanation. In order to effect the junction the electric line would have to sever land hitherto reserved by the trunk line for future sidings, and a clause was inserted in the Act securing to the trunk line the power of sale. Hence the carrying into effect of the scheme virtually rests with the decision of the Lancashire and Yorkshire directors as to whether they will hold the feeding of their line by the overhead or the prospective sidings in a specified position the more valuable. The carrying out of the scheme means direct connection between the south of Liverpool and Waterloo, Crosby, Formby, Southport, and especially by the West Lancashire route with Preston and the north. At present a large amount of traffic in South Liverpool remains undeveloped, and hence the Seaforth scheme has considerable popular support, which will grow as the scheme becomes better understood. It is not proposed to mix the electric and steam traffic, but both passenger and coal traffic would be exchanged.

Accidents.—While an electric car was proceeding along Myrtle-street, Liverpool, recently, an accident happened, the first of the kind since the electric system was adopted in the city. Owing to a sudden jerk or strain, a rosette broke away from the building to which it was attached. The rosette and several wires attached to it fell on the top of the car amongst the passengers. There was a general stampede from off the car, many persons complaining of being struck. The traffic was delayed for about 20 minutes.—Mr. T. E. Sampson, city coroner, last week held an enquiry into the circumstances attending the death of Christopher Wm. M'Gurn, aged 22, a labourer in the service of the Liverpool Corporation Tramways Committee, who was killed in Robson-street, Everton, through being struck by a falling electric wire. The coroner explained the nature of the enquiry, which was to ascertain, if possible, the cause of an iron strap breaking and allowing it to fall on the unfortunate youth, M'Gurn, killing him. The strap in question was put on the pole, and had not been finished in a way in which the Corporation would have taken it over for use by the tramways. It was waiting to be completed by the contractor before being handed over to the Corporation for use. On the day on which the occurrence happened there was a very severe thunderstorm, and also a severe storm of wind. Whether that caused an extra strain or not they would have to consider the possibility—at any rate, while the storm was raging the strap gave way. The jury found that death was accidental, and was caused by a defect in the strap, probably caused when being hammered over for bending on the anvil. They exempted the workman from blame, and recommended that the strap should be tested before being galvanised if possible. Two minor electric trolley wire accidents also occurred in the same city on the 23rd inst. The supporting span in Dale-street snapped, causing fusing of the wire and several explosions; while in London-road a trolley broke and fell among the passengers, but no injury was caused to any of them.—An accident also occurred near Dolly-mount, when two electric cars proceeding in opposite directions collided, whereby a driver was somewhat severely injured. There was practically no interruption of the traffic.

Ticket-Printing and Fare-Recording Machine.—A new method of collecting fares on the Leeds tramways is about to be introduced. Hitherto, what is known as the box system has been exclusively used. The reason for the change has not been officially stated, but the object is to prevent the leakage which it is believed exists. The *Leeds Mercury* says whether the appliance the Council are about to introduce will enable them to attain the desired ends remains to be seen, but that it is a very ingenious contrivance will be admitted. It is called a ticket-printing and fare-recording machine. The apparatus is contained in a case 5½in. square and 1¾in. in depth, and the conductor carries it in front of him strapped round his waist. As the name indicates, it is a ticket system, but, unlike that known as the "bell-punch," the ticket is printed by the machine as it is required, and upon it is recorded the date, the exact time of day it is issued, the sum the passenger has paid for it, the stage to which he is entitled to travel with it, and the number of the machine which printed it. The machine will likewise print an advertisement on the back of the ticket, and "spur" it so that it would be impossible to counterfeit it. Nor is this all. On the front of the case is recorded in figures the total number of pence which has been received for the whole of the tickets issued, and the number of passengers who have paid fares. Further, the sum which each passenger hands the conductor also appears on the front of the case. All this is obtained by a very simple process. When the passenger hands his fare to the conductor, he tells him the stage at which he wishes to alight. Say that he enters the Headingley car in Boar-lane, and intends to ride to the Oak. The fare is 2d., and on receiving it the conductor presses what is called the "plunger" on the upper side of the case twice. Each time a bell sounds, and simultaneously the figure "2" appears in a little disc in front of the case, where it can be seen; 2d. is added to the indicated total receipts, and "1" to the figures showing the number of passengers. To indicate the stage, a little switch near the "plunger" is moved. The printing of the ticket follows, and this is effected by the moving of a lever, which at the same time liberates the ticket from the interior of the case. One of the most curious parts of the affair is the recording of the time of issue on the ticket. In the left-hand corner of the case in front is a small clock, and by an ingenious internal arrangement a facsimile of the clock face is printed on the ticket. The advantage of the record is this: one of the drawbacks of a ticket already printed, and not showing the time of issue, is that

Digitized by Google

a dishonest conductor might procure it after it had been handed to the passenger, and dispose of it to another passenger, thereby securing for himself the face value. A conductor, however, would hesitate to resort to such dishonesty when the ticket bore the time of issue and was evidence against him. With such an appliance in use there would be no need for a waybill. As already shown, a check is supplied by the machine. At the office it would simply have to be noted whether the cash received from the conductor corresponded with the amount recorded on the front of the case. We understand, however, that men checkers will be employed to compare the figures recorded with the number of passengers on the car. The machine is the invention of Mr. Wilfrid I. Ohmer, and is manufactured by the Ohmer Syndicate, Limited, Suffolk House, London, E.C. The Tramways Committee have ordered 250, and the delivery of the first 50 is now due.

LEGAL INTELLIGENCE.

GUTTA PERCHA CORPORATION.

Meetings of the shareholders and creditors of the Gutta Percha Corporation, Limited, were held before Mr. Winearls, assistant-receiver, on Friday. This company, which was to trade in and manufacture guttapercha, was originally promoted by the Omnium Syndicate, Limited, and the Globe Venture Syndicate, Limited. The consideration was fixed at £150,000, of which £120,000 was for the letters patent and patent rights, and £30,000 for the stock of guttapercha leaves and other things sold to the company. The sale was conditional upon the company's proceeding to allotment before Oct. 14, 1897, on a subscription of £30,000. However, not more than £26,280 was subscribed for. The working capital was by a modifying agreement reduced to £10,000, but the provision that the vendor should underwrite £30,000 was not complied with. It now appeared that in spite of favourable reports in the propectus as to the patent process the company was not able to manufacture guttapercha of marketable value, and its total sales of stock amounted only to about £14. In the official receiver's opinion the purchase price paid to the vendors was very much inflated, and the action of the directors in proceeding to allotment upon insufficient subscription, contrary to the provisions of the purchase agreement, required further investigation. A report would probably be made with a view to obtaining an order for the public examination of some of the officers of the company. The statement of affairs disclosed total liabilities £20,303, of which £15,110 were stated to be unsecured, and no available assets, the whole of the amount (£5,195) being covered by debenture bonds. The total deficiencies as regarded creditors and shareholders was returned at £177,067.

It was resolved at both meetings that the official receiver should continue to act as liquidator under the proceedings.

COMPANIES' MEETINGS AND REPORTS.

W. T. HENLEY'S TELEGRAPH WORKS.

An extraordinary general meeting was held on Friday at Cannon-street Hotel.

Mr. Sydney Gedge, M.P., who presided, moved the confirmation of the resolutions passed on the 9th inst., providing that the ordinary capital should be increased from £150,000 to £200 000 by the creation of 10,000 additional ordinary shares of £5 each, to be issued to the existing ordinary shareholders *pro rata* at such times and at such prices as the Board should determine; also that the preference capital should be increased by the creation of 10,000 additional preference shares of £5 each, to be issued to the holders of the existing preference shares. The new ordinary shares are to be offered to shareholders at £10 each *pro rata* of one-sixth of their present holding. The Chairman said the price should be regarded as satisfactory, because, although it represented a premium of 100 per cent. to the Company, the market value of the shares was a good deal higher than £10.

The resolution was agreed to without discussion.

LEAMINGTON AND WARWICK TRAMWAYS.

The annual meeting of this Company was held at the Dale Temperance Hotel on Wednesday last week.

Mr. R. C. Heath, the chairman, who presided, said, with reference to the negotiations which had been going on between the boroughs of Warwick and Leamington, that the negotiations were proceeding at the present moment so far as the borough of Leamington was concerned. In the month of October they made up their minds with a view of obtaining provisional orders for both Warwick and Leamington, and also seeking to extend the line to Radford and along the Whitnash-road. They did not do this with any hostile view, but in order to save time if an agreement should be come to. With regard to Leamington the extensions were lost, and they were unable to come to any agreement, and they had up to the present time been unable to agree with Leamington. They went on with their negotiations, and were happy to say that they had come to an agreement with the Warwick Corporation, and that with their consent a provisional order was obtained for the working of the tramways by electric traction in Warwick for a lease extending over 28 years. That order had now become law, and, of course, they would in time make arrangements for converting the line. For that purpose they entered into negotiations with the British Electric Traction Company, because it was tolerably obvious that they were not strong enough to work the line themselves, nor able to find necessary capital without outside assistance. A reconstruction of that company would be necessary, and they hoped a number of old shareholders would join the new company.

The report, already noted by us, was adopted.

WINDERMERE AND DISTRICT ELECTRICITY SUPPLY.

The annual general meeting of this Company was held on Monday at Windermere, Mr. William Long, chairman of directors, presiding.

The directors' report for the year ended Dec. 31, 1899, stated that the year's trading profit amounted to £1,112, and after bank interest and other payments a balance of £970 was left, of which £949 had been applied to payment of dividend on preference shares. The Company had acquired the entire property and goodwill of the Keswick Electrical Company, and had come to an agreement with the Ambleside District Council to take over their provisional order. The amount available for dividend had been affected by the rise in the cost of coal.

On the motion of **Mr. Long**, seconded by **Mr. J. Raworth** (London), the statement of accounts was adopted.

Mr. Raworth, remarking on the non-payment of a dividend on the ordinary shares, said that most of the best electric supply companies had passed through that stage. Owing to the increased price of coal the directors contemplated raising the price of their light from 6d. to 7½d. per unit.

Mr. F. Fowkes, managing director, in reply to questions, said there was no connection between the Windermere Company and the British Electric Traction Company.—*Yorkshire Post.*

WIRRAL RAILWAY.

At the half-yearly meeting of shareholders in the Wirrall Railway Company on Monday,

Mr. T. H. Jackson, who presided, in proposing the adoption of the report, said that having obtained powers to work the line by electricity, the change would be proceeded with when a favourable opportunity presented itself. They hoped for good results from its adoption.

BLACKPOOL AND FLEETWOOD TRAMROAD.

The ordinary general meeting of this Company was held at the Company's offices, Fleetwood terminus, last week. The report, already noted by us, was adopted. A number of long speeches were made, and a vote of thanks was passed to the directors for the way they had conducted the Company's business.

PROVISIONAL PATENTS, 1900.

AUGUST 20.

14868. Improvements relating to the insulation of electrical conductors. William Alfred Phillips and Charles Eyre Kent, 323, High Holborn, London.

14877. An improved dynamo-electric machine and regulator therefor. Joseph Dentel and Maximilian Junka, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

14893. Improvements in electrical measuring instruments. Llewellyn Birchall Atkinson, 1, Queen Victoria-street, London.

14895. Improvements in electric ignition plugs for internal-combustion engines. Frederick Richard Simms, 4, South-street, Finsbury, London.

AUGUST 21.

14906. Improvements in or connected with sectional conductor street or road electric railways. John Milnes, 15, Water-street, Liverpool.

14924. Improvements in electric accumulators. Harry Rose, John Halifax, and Charles Henry Antrobus, 5, Hatton-garden, London.

14943. Improvements in switchboards for telephone stations. Milton Izatus Baird, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

AUGUST 22.

14971. Incandescent electric lamps. James Swinburne, 82, Victoria-street, Westminster, London.

14972. A new or improved arrangement for automatically lubricating the spindles of dynamos. William George Graham, 100, Wellington-street, Glasgow.

15001. Improvements in electric measuring instruments. Arthur Honig, 67, Sutherland-avenue, Paddington, London.

15019. Improvements relating to the recovery of tin and the simultaneous generation of electric energy. Robert Howe Gould, 45, Southampton-buildings, Chancery-lane, London.

Digitized by Google

15021. Improvements in the manufacture of carbon electrodes for arc lamps. Varsonophy Alexandroff, 24, Southampton-buildings, Chancery-lane, London.

AUGUST 23.

15095. Improvements in electrical demand indicators. The Reason Manufacturing Company, Limited, Norfolk House, Victoria-embankment, London. (Arthur Wright, high seas.)

AUGUST 24.

15123. A new or improved electrical arc lamp. Nettlefolds, Limited, and William Edward Symons, 7, Staple-inn, London.

AUGUST 25.

15146. A new or improved electrical hauling apparatus. Thomas Greensmith and Matthew Brown Wild, 70, Market-street, Manchester.

15187. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William J. Davis, jun., United States.) (Complete specification.)

15168. Improvements in commutators for electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (John T. H. Dempster, United States.) (Complete specification.)

15169. Improvements in rectifying alternating electric currents. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Elihu Thomson, United States.) (Complete specification.)

15175. Improved apparatus for igniting by electricity combustible mixtures in internal-combustion motors and the like. Arthur George Bloxam, Birkbeck Bank-chambers, Chancery-lane, London. (Alfred Schoeller, Germany.)

15193. A new or improved method for adjusting electrodes. Russell John Reynolds, 99, Cannon-street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Sept. 15.

1899.

17159. Electricity meters. Hookham.

19445. Electric lighting systems. Blondel, Weissmann, and Wydts.

20615. Electric safety apparatus for lifts and elevators. Bush and Jenkins.

20906. Trolley standards used on cars or wagons electrically propelled from an overhead wire. Munro, Wood, Brecknell, and Rogers.

23504. Receiving apparatus for Hertzian radiations or electromagnetic waves. Baviera.

1900.

10318. Electric storage batteries and conducting plates therefor. Fell. (Wiegand.)

10502 Telephone systems. Ritter.

11819. Instrument for measuring rotary field currents. Siemens Bros. and Co., Limited. (Siemens und Halske Aktien-Gesellschaft.)

13044. Electric railways in which transformers are carried on the train. Siemens Bros. and Co., Limited. (Siemens und Halske Aktien-Gesellschaft.)

TRAFFIC RETURNS.

NOTES.

Wireless Telephony.—After wireless telegraphy, wireless telephony was bound to appear sooner or later, and we notice that it is announced that a system of wireless telephony has been discovered by Mr. Walker Moseley.

The New German Cable.—The new German-American cable between Emden and New York was opened on Friday, when the Emperor William sent a message to President McKinley and President McKinley replied. The cable was opened to the public service on Sept. 1, when the old route, from Emden *vid* Valencia (Ireland), was discontinued.

Electricity in Liverpool.—It is pleasing to notice that the demand in Liverpool for electrical energy is increasing to a very large extent. The chief cause of the increase is naturally the electric tramway system, but the demand for energy for other purposes has also become much larger. The great increase has naturally brought about some changes in the staff of the electricity works, and many of the officials have received well-deserved promotion.

A Piano Note Recorder.—An invention has, we learn, been completed by which such things as "lost chords" are to be prevented. Thus we notice in the *Globe* the announcement that Mr. Vaughan Neale has completed an electrical machine which is to register extempore compositions upon the piano. The arrangement can be attached to any ordinary piano, and it is reported that the machine has taken down a tarantella played at the rate of 2,000 notes a minute. The attachment, it is stated, does not interfere with the touch.

Sunderland Tramways.—The new electric tramways recently started by the Sunderland Corporation do not seem to have escaped the delays and stoppages which usually attend the opening of a new line. Thus, on Sunday last, in the afternoon, the current was suddenly cut off on two of the sections on the Christchurch-Roker route, and two or three of the cars were compelled to remain for about an hour at different places on the line. The service was naturally greatly disorganised, but at present no explanation is forthcoming as to the cause of the interruption.

Motorcar Speeds.—The inhabitants of Bournemouth have been greatly annoyed that motorcars should travel in that town at any speed above a walking pace. In consequence of their complaints, several drivers of motorcars were recently brought before the police court. The constables gave evidence as to measuring the distance travelled by the cars, and the time, which, when worked out, averaged 10 miles per hour. The traffic was fairly heavy at the spot where the measurements occurred, but the magistrates let the drivers off with only nominal fines, taking the view that none of the cases were serious.

French Translation.—In a note in our contemporary *L'Electricien* on the electric lighting stations in England, a number of figures are given as to the output, cost of machinery, and price per unit at various stations. Our French contemporary, however, does not yet seem to have mastered that strange conglomeration of "exceptions to the rule" which goes by the name of the English language, and while giving a working cost as 1·5 pence, when giving the total cost as 2·18 pence treats us to a double plural and calls it 2·18 pences. In yet another note, also, our contemporary gives the fare on the twopenny tube as two pences. Apart from this, however, the notes contain a large amount of useful information.

African Telegraphs.—The line of telegraph from the coast to the Lake Victoria Nyanza has recently been completed, and the advantages which it will confer on the inhabitants of Lower Egypt will be enormous. As is well known, the natives depend on the rise of the waters of the Nile for the irrigation of the land, and hitherto they have only known a very short time beforehand the condition of the waters. Now, however, that communication has been made from the sources of the Nile, the required information can be sent several months in advance, and the Egyptians can regulate their supplies. Messages, also, are now sent in a few days which previously took seven months to communicate.

Wireless Signalling.—Mr. J. Gardner, of Fleetwood, is stated to have invented a new automatic device for signalling at sea. The mechanism is said to consist of a specially-cut wheel, which controls a Morse key at the transmitting station. The dots and dashes are recorded on the tape in the usual way. At a trial made at Fleetwood a wire was erected on shore at the transmitting station, and a conductor of about the same height was attached to the mast of a vessel lying off the coast. The vessel was then towed out in the direction of the Morecambe Bay lightship. When about two miles out signals were sent and received. The record was taken up to the seven miles limit, the extremity of the zone provided for.

Edison Again.—Mr. T. A. Edison is credited with yet another great invention, this time it being announced that he has completed a machine for the generation of electrical power direct from coal without the use of engines or dynamos. Mr. Edison declares that his invention will practically do away with the use of steam, and make it possible by electricity to run ships across the Atlantic in four days. He also says that under his new system private electric lighting plants may be maintained in houses at small expense. We believe we have seen the same announcement in a slightly different form some considerable time since, but after going the rounds of the provincial Press no more was heard of the matter.

Liverpool Electric Tramways.—Last Saturday another portion of the electric tramways in Liverpool was opened for traffic, and through communication is now established between Seaforth and the suburbs of Waterloo and Great Crosby. The scheme was entrusted to the Overhead Railway Company to carry out, and work was commenced almost a year ago. The overhead trolley system is used, with side-pole construction for supporting the trolley wire. The cars are similar to those already in use in Liverpool, and the electricity is to be supplied from the Overhead Railway Company's station at Bramley Moore Dock. The fares charged on the route are remarkably low, and tickets will be issued to and from all stations on the Liverpool Overhead Railway. A luncheon was given by the chairman of the Waterloo District Council to the gentlemen connected with the construction of the line.

Hull Telephones.—The Hull telephone subscribers seem to have fallen on bad times. Thus we notice that on Monday last the members of the Hull Chamber of Commerce had brought before their notice what was described as the "defective telephonic system of Hull." One of the speakers said the system was simply abominable, especially when anyone wanted to speak out of the city. In many cases he had no sooner started to talk through the instrument than he was cut off. The Chairman (Mr. T. R. Ferens) also remarked that he had only used the trunk system once in six months. If he wanted anything quickly, he telegraphed. The telephone system was now a nuisance, and the trunk line, as now conducted, a failure. It was eventually decided

Digitized by Google

that the attention of the Post Office authorities and the National Telephone Company should be called to the defects in their systems and asked to remedy them.

The Healthful Tube.—The Central London Railway, or, as it is more familiarly called, the twopenny tube, has received a considerable amount of praise in various places, owing to its superiority in certain things. One is, however, rather startled when it is suggested that, instead of taking the sea breeze at Brighton, one should travel on the tube and get the same vigorous appetite which the ozone by the sea is supposed to produce. The *British Medical Journal*, however, quotes the case of a person who had suffered from anexoria for 18 months suddenly developing a ravenous appetite after a single journey on the new line. The satisfactory condition of affairs—from the patient's point of view—has since then been maintained by similar doses taken every two or three days. Tonics have become needless, and the price of the journeys forms a most profitable comparison with previous cost of medicines and doctors' bills. The twopenny tube, as a health resort, promises to rival Davos Platz.

High-Voltage Domestic Supply.—The Board of Trade rules have, during the last two or three years, been found to be exceedingly irksome in the matter of electric supply. Thus, referring to the fact that a deputation of representatives of several electric lighting companies lately waited on the President of the Board of Trade to obtain an alteration of the regulations regarding electric supply, *Feilden's Magazine* says: "It appears that the President of the Board of Trade has not been sufficiently impressed by the deputation which recently waited upon him on behalf of eight metropolitan electric lighting companies in order to convince him of the desirable necessity for an amendment of the regulations on the change in the pressure of supply to consumers. This is to be regretted, but still more is it to be regretted that any hard-and-fast rules regarding technical details were fixed by legislation at a time when electricity was as yet, with reference to many questions, in a purely experimental stage."

A Peculiar Tramway Accident.—An extraordinary accident occurred on Sunday last on the St. Helens and District Tramways system. Thus about noon one of the newer and larger cars was being taken from the sheds to the starting place at the junction of three large streets. The guard was new to the business and omitted to properly attend to the trolley, and consequently, as the car turned into Bridge-street, the trolley, being on the wrong wire, swung outwards, following a different course. The strain became very great, and the trolley left the wire. It came back with a crash, bringing down nearly all the wires at the junction, and interrupting practically the whole of the system. At the instant of the crash, apparently, a short occurred, while the arm on which an arc lamp is suspended at the corner of one of the streets was broken and the lamp shattered. At the works it was soon seen by the indicator that something was wrong, and the current was switched off, the cars on the Haydock, Denton's Green, Peasley Cross, and part of the Prescot sections being left standing still at various parts of the town. Breakdown gangs were immediately set to work, and the damage was repaired in the very short space of time of three hours.

A Ballistic Oscillometer.—The following is an abstract of a paper read by Messrs. A. and V. Guillet before the French Academy of Science. The abstract appears in the *Electrical World*, and reads as follows: "The authors start from the rule that when a coil supplied with a certain current oscillates in the inner part of a fixed coil supplied with the same current, the product of the current and the period of the oscillations is constant, therefore the number of oscillations during a certain time is proportional to the quantity of electricity supplied during that time; this rule is used in the counters of Vernon Boys and Blondlot. The energy cannot be measured in the same way; to measure it, not continuous current is supplied to the oscillating coil, but only a current that lasts for a moment. Let the coil oscillate around a fixed axle in a magnetic field, then it can be shown that if the magnetic field is constant a certain angle of oscillation corresponds to a certain quantity of electricity; if the magnetic field is proportional to the E.M.F., the angle of oscillation corresponds to a certain amount of energy. The first case is obtained with a permanent magnet, the second by means of a coil, in shunt, for producing the magnetic fields."

An Inexpensive Cooling Tower.—The *Electrical World* illustrates a cooling tower which has been used by the electric lighting company in Jersey City, but which, we are afraid, is not likely to find much demand in or around the large towns on this side. The apparatus in question is practically a cooling tower without any enclosing work, and the water is delivered at the top of an erection of scaffold poles, across which five platforms at different heights are placed. These platforms are made up of lattice woodwork, and break up the water as it falls down from one to the other, the water at the bottom being collected in a pond for use over again. Illustrations are given of the apparatus when working and when at rest. From the photo taken when the water is being discharged, we can see that in windy weather the spray would be carried for a great distance, which would cause a nuisance to the surrounding property owners. In fact, the general idea is not unlike that of the original condenser water-cooling apparatus at St. Pancras, the use of which had to be discontinued. In this case a galvanised iron structure with iron plates was built up round the chimney, but it used to shed ice in winter and spray in summer, which led to its disuse.

The Northampton Institute.—We have received a copy of the announcements of the Northampton Institute for the session 1900-1901. The book is much the same in appearance as in past years, but new illustrations have been introduced. The volume commences with a list of the staff, and with respect to the electrical engineering section we do not notice any special change, except that Mr. A. W. Martin, who was an assistant lecturer last year, has taken the place of Mr. A. Brooker as chief lecturer in the postal telegraph classes. As to the classes themselves, we learn that the only new feature of any importance is with respect to the engineering day classes. These are divided into three classes: mechanical, electrical, and horological engineering. In each the work consists of lectures, exercise classes, laboratory work, drawing office, and workshop practice. In the electrical engineering department, besides instruction in electric lighting and power distribution, electric traction and electro-chemistry will be dealt with. Before entering these classes, students have to pass an examination in general knowledge. The fee for students is £15 for the session. There are numerous other classes for all kinds of subjects, and there is also a social and recreative section, which includes music, swimming, athletics of all kinds, etc. Dr. R. Mullineux Walmsley, the principal, is much to be congratulated on the great success of the City Polytechnic in past years, and we are sure that in the session now about to commence the standard of work will be quite up to, if not higher, than in previous years.

Electric Railways.—The District and Metropolitan Railway Companies are waking up to the fact that for lines of railway between the City and suburbs steam is becoming out of date. Thus, when interviewed by the *St. James's Gazette* recently, Mr. Powell, the general

Digitized by Google

manager of the District Railway, is reported to have stated that as regarded the proposed new electric motive power to be applied to both the District and the Metropolitan underground lines, tenders had been invited from engineering firms for the reorganisation of the systems upon an electric motive basis. There were, however, so many details to be considered that firms were at present only making enquiries into the conditions. Tenders would not be ready for some few months, and after that it would be a considerable time before the matter was completed. There was nothing like the amount of work to get through, however, that the Central Electric had, as they had their tunnels, stations, and carriages made. With regard to the carriages, he thought the directors would favour the old form of doors to each compartment, and not the corridor system. Unlike the Central Electric, they would carry the luggage of the passengers. They were a railway, not a tramline. One of the reasons why the corridor system of carriages would not be adopted was that the public, and especially the women, were not educated up to it. They did not get out of the carriage fast enough with their luggage. There was little doubt that with the new system they would be able to do the through journeys very much quicker. An additional improvement, in our opinion, and probably of others who have travelled by the line, is that the very objectionable smell and smoke which at present exists in the tunnels, and even in the stations, will be done away with, and one will not feel half suffocated at the end of a journey.

The Energy of Cathode Rays.—At the recent meeting of the American Association for the Advancement of Science a very interesting paper was presented by Mr. W. G. Cady, dealing with the subject of "The Energy of the Cathode Rays." The paper, which is abstracted in the *Electrical World*, gives an account of investigations at the Physical Institute of the University of Berlin, made in order to determine the relation between the energy and other discharge phenomena of these rays. For this investigation the thermo-element, as used by Messrs. J. J. Thomson and O. Berg, was employed, as much more exact than the calorimeter. Observations were also made with bolometers. The bolometer formed one arm of a Wheatstone bridge. The paper is in reality an experimental test of the emission hypothesis which Prof. Merritt supported in his vice-presidential address. By that hypothesis, a relation exists between the energy of the cathode rays, potential of discharge, and amount of electricity transported by the rays, which is expressed by several equations, of which the crucial one is : $\frac{i\,V}{Q} = \frac{1-r}{1-r\,r'}$; where i is the intensity of the cathode current, V the potential of the cathode giving off a bundle of rays, Q the amount of heat given up to the conductor (ergs per second), r is the fraction of the rays reflected, and the ratio $r' : 1$ expresses the ratio in which rays lose their energy on reflection. The conclusion reached by comparing the limiting value of the ratio experimentally determined with this equation is in contradiction with results obtained by Merritt. Thus if $r = 1$ (Merritt), we still have $i\,V/Q = 1$; if in the limiting case $r' = 0$, then $i\,V/Q = 1 - r$. But Starke has found that platinum (the reflecting surface of Cady's bolometer) reflects about 40 per cent. of the rays. Assuming, therefore, that for the bolometer $r = 0{\cdot}4$, we find that when $i\,V/Q = 0{\cdot}83$, $r' = 0{\cdot}7$. The importance of this investigation on the vexed question of the nature of cathode rays is evident, since the result, if established, is incompatible with the emission or corpuscular theory.

Magnetisation and Elasticity.—The last of the papers upon "The Effect of Magnetisation upon the Modulus of Elasticity," by Mr. J. S. Stevens, appears in the August number of the *Physical Review*. In the previous papers he discussed the relation between magnetisation and the moduli of flexional and torsional elasticity. The two papers in the current issue deal with the elasticity of traction and compression. In the first case the apparatus consisted of a coil of wire wound on a brass tube, through which passed a stream of running water, in which was carried the wire to be tested. One end of the wire was fastened to a rigid support, and the other to a bent lever with a multiplying power of about 11. At the other end of the lever were attached weights giving a certain tension to the wire. The changes in length were communicated to another arm of the same lever, which multiplied the effect 110 times. The fore end of this lever moved under the field of a micrometer microscope. A thermometer with its bulb in the water completed the apparatus. The procedure consisted of setting the cross wires of the microscope on some point for zero, then turning on the current and noting the deflection of the end of the lever. The author then gives tables giving the current, zero readings, difference, and the change in length of the wire. From the tables he concludes that the modulus of elasticity of traction increases when the body is magnetised. The increase is fairly proportional to the magnetising force. With the same wire the change in the modulus varied with the stretching weight. With wires of different cross-sections stretched by the same load the change in modulus was greater in the smaller wire. In experimenting as to the elasticity of compression, a bar was firmly fastened at one end, and moved a lever arm when changing in length. The other arm of the lever moved under the field of a micrometer microscope. The compressing force was measured by a spring balance. The whole apparatus was bolted rigidly to the bed of a planer, so that there was little chance of friction or slipping. The knife-edges and bearings were of hardened steel, and variation of pressure was applied by moving the bed-plate of the planer. With respect to this experiment, the author states that within its limits magnetisation does not change the elastic modulus for compression. If it had been possible to apply a pressure nearer to that of the elastic limits of the metal, the results might have been different.

The Central London Railway.—Numerous letters have been sent to the *Times* concerning the Central London Railway, and the one or two serious stoppages which have occurred upon it. The stoppages one would naturally expect on an entirely new railway, and the Central London Railway Company are to be congratulated on having started the line with so few of them. The first of the letters was from a gentleman who had been stopped for half an hour at Marble Arch, and to this Sir Benjamin Baker replied explaining the means for getting the passengers away from the train in the event of a stoppage. Mr. R. W. Boyd is not, however, quite satisfied with Sir B. Baker's explanation, and submits one or two points for consideration. Thus, he says that Sir Benjamin tells the public that in the event of a prolonged stoppage gangways are provided for passengers, but these gangways lead, it appears to him, nowhere, unless the train is at station, at which point the main tube is enlarged. Gates are provided between the carriages, but these gates are hardly available for the use of passengers unassisted by the guard, while all side outlets are useless between the stations, as the train fits the tube closely. This close-fitting construction prevents escape from the train while in the main tube, and this seems to him to be an element of considerable danger. As to the lighting, a prolonged stoppage occurred with carriages full of people and the lights extinguished. The

Digitized by Google

carriages are supplied with some oil lamps in addition to electricity, but these he thinks are so few as to be of little use in a panic. Finally, to reduce the risk of accident, he suggests that it would be well to have a short, simple printed notice fixed in each carriage explaining what to do in case of accident or prolonged stoppage. Another gentleman, who would certainly seem of a rather timid disposition, describes very graphically his experience on Aug. 18, when a stoppage occurred between Holland-road and Notting Hill-gate. After being kept prisoners in the darkness for about two hours and a quarter the passengers had to walk back to Holland-park Station. Some nervous lady passengers, he states, were almost terrified into hysterics by vague fears of a horrible death caused by touching the electric rail, and the wanton action of the officials in refusing all explanations of the delay and keeping them imprisoned for so long must, he thinks, necessarily militate against the success of this new method of locomotion. The accident occurred apparently from a train running off the line at the points, an experience which he seems to think very often occurs to electric trains. He, however, has taken the right course to avoid any such delays by the Central London Railway in future, as he practically expresses his determination never to trust himself on it again.

Corridor v. Compartment Cars.—In comparing the relative advantages of English compartment cars and American long open cars, particularly in regard to the rapidity of filling and emptying, the New York *Commercial and Financial Chronicle* says that where the traffic is very large, as at the chief city stations, the many compartments of the English car undoubtedly enable more prompt ingress and egress on the part of passengers than the car with only end doors. But cars coming into a station filled with passengers are not usually promptly forwarded with another full car-load of passengers. This is particularly true in suburban service, in which the new Central London underground road is engaged. Each station has its proportion of passengers alighting and boarding the cars, and under these circumstances the quick handling of passengers with the compartment car, as at great terminal stations, is not maintained. There are a number of reasons for this which make the result quite obvious. With compartment cars the selection of a comfortable seat depends upon the choice made from the station platform. First, the particular class for which the ticket is good has to be found. Passengers examine each separate compartment until they find the seat they regard as the best—two operations which consume time. The assorting and distribution of passengers in the open American car is, however, accomplished after the passenger has entered the car and when the train may be in motion. Where compartment cars are used, this distribution must be done while the train is at a standstill at the station platform. These generous statements of the quicker handling of passengers at way stations and in the frequent stops of a rapid transit service, with the American open car having end doors, are amply verified by careful observations of the actual time consumed in the two services. One observer, Mr. R. H. Soule, a well-known American railroad officer and engineer, has recently published figures comparing the length of service stops on the Cape Government railroads in Africa and on the Illinois Central in its suburban service at Chicago. In each case 100 observations were taken. Roughly, Mr. Soule's figures show that the American train stops were but half as long as those on the African line, with its English rolling-stock. The actual figures, reduced to an average for the series of observations, were 22·39 seconds for each stop on the African road, while but 11·58 seconds were consumed on the average by the Illinois Central trains. This represents the view taken by the companies. The passengers, especially those in England, who are accustomed to the compartment system and its attendant comparative privacy, firstly miss the latter, and, furthermore, are not all favourably impressed with the constant interruptions, the inconvenience caused by people standing in the passages and front of the passengers already seated, etc. Another point is that the introduction of the one-class system in England is, when two different fares are charged, distinctly unfair to those paying the higher fare.

Spark Length.—In the *Physical Review* for August we notice a short contribution by Mr. W. J. Humphreys on spark length as modified by solid dielectrics. In the note the author states that whilst trying some experiments with an electrical influence machine he noticed that the spark length was greatly increased by the presence of solid dielectrics, such as glass or ebonite, near the positive pole. Several machines were experimented with, but the one commonly used was a two-plate Wimshurst machine with plates of ebonite 20in. in diameter, and furnished with metallic sectors. The apparatus used was two small Leyden jars with their outer coverings connected by a wire and their discharging balls connected, one to the positive side of the machine and the other to the negative side. The inner coatings of the jars were oppositely charged, and the distance between the discharging balls increased until sparks ceased to pass. When, however, the same potential difference being maintained, a glass rod was placed near the side of the positive pole facing the negative, a full spark passed. This did not happen with the rod near the negative pole. Various dielectrics were used, but with the same result, the increase in spark length being always well pronounced and sometimes doubling the ordinary length. Many combinations were tested, but in every case the results obtained were practically the same. In framing an hypothesis to explain the phenomena the author suggests that "the dielectric between two poles is most sensitive to electrical disturbances at points next the anode." To support this theory the author gives a number of facts—namely, that the spark length is increased by the presence of a glass rod next the anode, but not when the rod is in any other part of the field; the greater the increase in spark length, the nearer must the rod be brought to the pole. The greatest increase is obtained with a rod of a certain size—*i.e.*, the rod must not be too large or too small to produce the best results. When glass fibres are used, they must be brought very near the pole or quite in contact with it. The same phenomenon occurs when insulated conductors are used instead of glass or any other dielectric. In order to test this idea, the author experimented with dielectrics of widely differing inductive capacities, but otherwise approximately equal. The substances used were a thin-walled test tube empty, a similar tube partly filled with water, and a similar tube filled with metal. The results were not conclusive, the increase in spark length being nearly the same, with, perhaps, a slight advantage in favour of the tube containing water. The fact also that insulated metal rods act no better than glass rods does not, the author thinks, seem altogether in accordance with his assumption. These, however, were the only objections, which may not be fatal, and in further support of the hypothesis the author give the increase of spark length caused by a small spark drawn from the negative pole of two oppositely charged Leyden jars with the outer coatings connected, and also Faraday's experiments on spark lengths between spherical electrodes of different sizes. Mr. Humphreys states that

Digitized by Google

whatever may be the real action of solid dielectrics in increasing the spark length, it is a phenomenon of the anode, and to that extent indicates a greater sensitiveness of the air about this pole to electrical disturbances.

Municipalities and Public Service Companies. Mr. A. R. Foote has during the last few years been investigating the principles which should govern contracts between municipalities and public service corporations, such as tramway, electric lighting, etc., companies. This work appears as a series of Bills prepared by Mr. Foote at the request of the Ohio State Board of Commerce for presentation to the Ohio Legislature at its last session, and while action upon the Bills was deferred until the next session, it is expected that they will be taken up for consideration next winter. The essential provisions of these Bills, as given in a recent number of the *Street Railway Journal*, are as follows: (1) Bonds issued by a municipality for the establishment of a public service plant shall be secured only by mortgage of the plant itself and the franchises for operation. In other words, the general credit of the city shall not be placed behind these bonds, but they must stand or fall upon their own merits and earning power. (2) No public service owned by a municipality shall be sold for less than cost. If the service does not pay at the prices originally established, these prices must be increased. The general body of taxpayers must not be called upon to help pay for a service to a private user. (3) The true and entire cost of service, whether given by a private company or by the municipality, shall be determined by a State auditing department to be established, and shall include the full operating expenses; a sufficient provision for depreciation, for losses from fire, and for accidents of every kind; taxes paid (in the case of private companies) or relinquished (in the case of municipalities), these taxes including any special bargains concerning franchise taxes which may be made between municipality and company based on a payment of percentages on gross receipts; interest on the full amount of actual investment at the rate per cent. paid by the municipality on its bonded debt. (4) To the cost of service as above specified there should be added in the case of enterprises owned and operated by the municipality a provision for a sinking fund sufficient to pay off at maturity the bonds issued on investment account. (5) All surplus earnings over and above the true cost of service, as defined in paragraphs 3 and 4, are to be regarded as the true profits of the enterprise. (6) Out of these true profits, when earned by a private company, the latter may pay upon its true investment a rate per cent. double that paid by the municipality on its bonds. (7) If a private company adopts a system of profit-sharing with its employés, it shall be entitled to earn and pay to the employés the same rate per cent. upon the wages earned by them as the company earns on its investment. (8) All surplus profits, after making the distributions provided for in paragraphs 6 and 7, are to be divided equally between the municipality and the company. (9) The determination of the investment value to be used as a basis for the foregoing computations shall be determined originally by appraisement or by arbitration. Additions shall be made in a manner specified by the municipality. (10) The price for service to be paid by users shall be fixed by the municipal council for a period not less than five nor more than 25 years, and the prices so fixed shall be computed on the basis of cost, and must be such as to produce an annual revenue sufficient to fully pay all costs and to yield the company its authorised share of profit. These rules, which are very well drawn up, would, if adopted, probably prove of great use to the parties concerned in the contracts, and would doubtless save a very large amount of friction. It is, however, doubtful whether both municipalities and public companies could be brought to accept them as they are, and possibly, although the rules seem very fair all round, in practice many difficulties might be found in the working which did not appear in the first instance.

Electrical Stage Effects.—In most of the modern plays at the larger theatres electricity is used to produce particular and striking effects. We notice an instance of this in the *Scientific American*, which has an article respecting the production of "Bén Hur" at the Broadway Theatre, New York. In this play a chariot race takes place, and the stage is so fitted that two chariots, each with four horses, appear to be dashing along at a great pace. Finally, one chariot overturns the other and wins the race. A large part of the illusion depends upon the background, which gives the idea of positive motion, and the one employed in this instance embodies means for mounting and driving travelling aprons at the rear and sides of the stage, so as to prevent any break in the scene, this giving the audience the impression of change of scenery. At the rear of the stage is an endless apron, flanked on each side by smaller endless aprons, each of which is complete in itself, but are operated in unison. Upon these aprons are painted representations of the background of the scene; in this case representing the antique circus at Antioch filled with spectators. Directly below the chariots is the electric motor which actuates all three aprons of the panorama. It is a 5 h.p. Lundell motor, and is operated by an assistant, who stands at the switchboard and receives the signal of the stage manager by a flash of a coloured electric lamp. A twisted belt imparts motion to a vertical shaft upon which are three pulleys, one to receive the power from the countershaft and the others to transmit the power to the two ends to vertical shafts, which each carry a cylindrical drum, around which the aprons are passed. Their rotation causes the apron to travel continuously, and gear wheels are provided, which impart motion to the side aprons, so that they are all driven in the same direction, and to the spectator the three aprons appear to be a continuous, unbroken scene. In spite of the fact that the panorama is 96ft. wide and 25ft. high, the three panoramas are all rotated at a speed of 2,000ft. per minute by a 2-h.p. motor. As to the chariots themselves, the treadmills carrying them are placed immediately beneath the stage, and are covered by sections of planking, which are removed and carried out to the wings when the race is to take place. There are eight treadmills, one for each horse. The chariots are two in number and each is supposed to be drawn by four horses. The chariot of Ben Hur is not a trick chariot, but that of Messala is arranged to go to pieces when struck by Ben Hur. The chariot wheels do not rest upon the floor of the stage, but are supported upon metal yokes. The wheels are actuated by a small electric motor inside the body, and can be switched on by the drivers. Both chariots have these motors, and current is obtained by the aid of plugs which are inserted in the floor. The chariot of Messala is arranged so that at the critical moment when Ben Hur strikes it, by dropping a catch, powerful springs on the axle throw the wheels off and the body of the chariot drops upon a yoke which is provided with springs. To simulate the dust raised by the chariot wheels, a combination of powders is forced out underneath the horses' feet and behind the chariot wheels. This is accomplished by a blower in the cellar, driven by the same electric motor which actuates the belts. The scene can be fitted up with wonderful celerity, the whole requiring only about eight minutes to set.

TAUNTON ELECTRICITY WORKS.

(Concluded from page 298.)

Mr. Manville in his report, which is dated March 25, 1898, alludes to the early start made at Taunton in electric lighting, as plant was put down in 1895, and he expresses his opinion that in view of the then knowledge of electrical engineering, and also of the knowledge acquired at the time when the incandescent plant was laid down, that those responsible for the equipment of the station had not been wrong in their choice of a system.

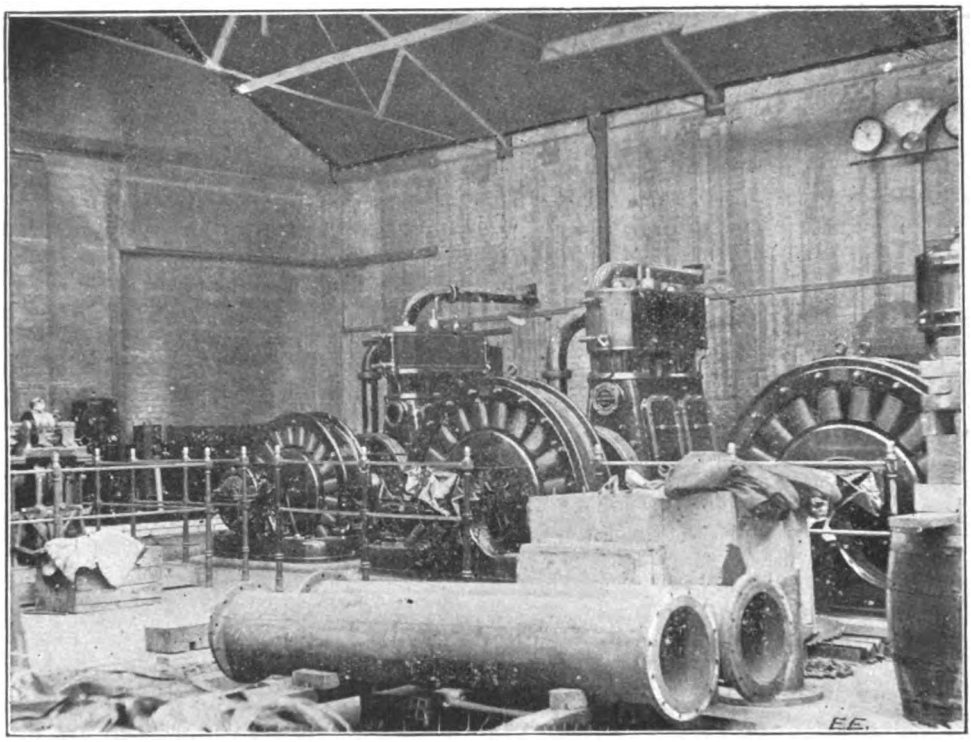

FIG. 4.—View of the Taunton Engine-Room under Process of Alteration.

At the time the report was written, however, the machinery which was to be recommended in 1897 was quite out of date. Mr. Manville regretted that extensions had been made which rendered the change over to a more modern system somewhat costly. The point arose that it was not possible under the Local Government Board regulations to obtain a loan for the whole of the proposed new expenditure, as the Board will not sanction loans for the renewal of plant, it being deemed that such renewals should come out of revenue. By a judicious arrangement made with the British Thomson-Houston Company, whose predecessors had supplied the original alternators, the consulting engineers succeeded in arranging that the new plant should be installed without a charge against the revenue. This was so because the Corporation had purchased the plant at a favourable price, and also had written off each year an amount for depreciation and for the sinking fund on the previous loan. The arrangements made in changing over were that the three largest alternators should be returned to the makers, who supplied instead two alternators of 75 kw. and one of 150 kw. output. These new machines have a frequency of 60 as against

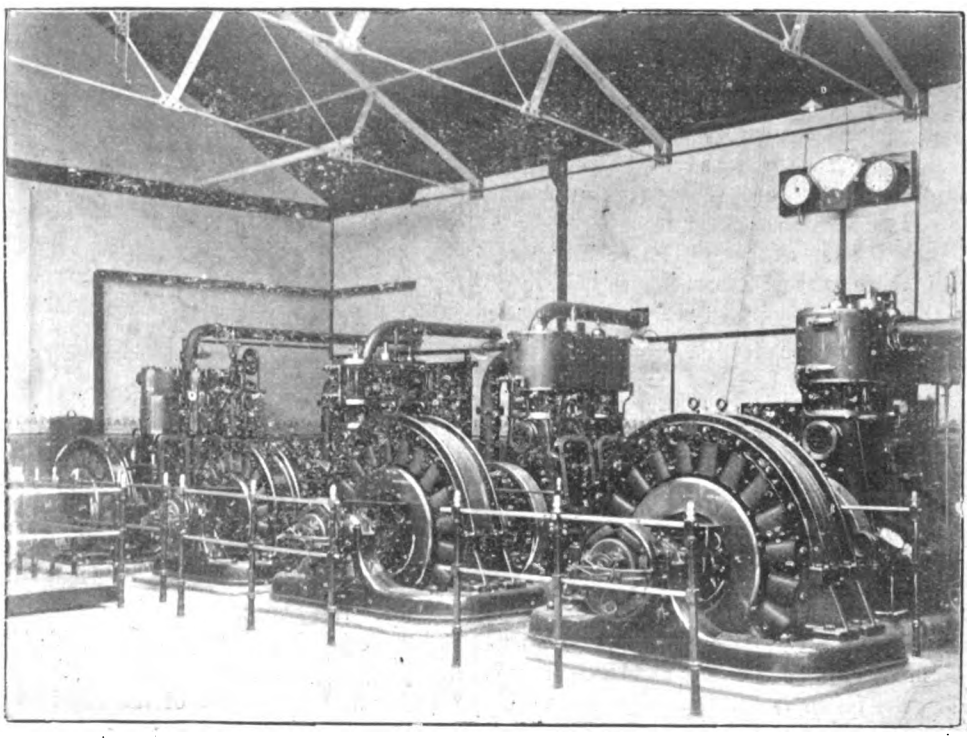

FIG. 5.—Taunton Engine-House Plant as Remodelled.

Digitized by Google

the old frequency of 125. The Belliss engine already used in the station for driving by means of belts was under the contract directly coupled to one of the 75 kw. machines. The other machine of same output was coupled up to a Willans engine, which was constructed out of the best parts of the two Willans engines on the works. This shows the great advantage of having standards in manufacture, as the parts of these engines, after having been subjected to severe working conditions during a number of years, were still able to be interchanged indiscriminately. In this way a really good engine could be built up out of the best parts of two engines which were not in a good state of repair. If the engines had not originally been made to templates and gauges, this would have been utterly impossible.

The great alteration in the appearance of the station from the substitution of these direct-coupled sets for the belt driving can be seen by contrasting Figs. 4 and 5 with Figs. 2 and 3 in our last issue. The photograph from which Fig. 4 was prepared was taken when the reconstruction was under way, and Fig. 5 shows the engine-room in its completed state. In the boiler-house an additional Babcock and Wilcox boiler was added, and a completely new range of steam and exhaust pipes was installed.

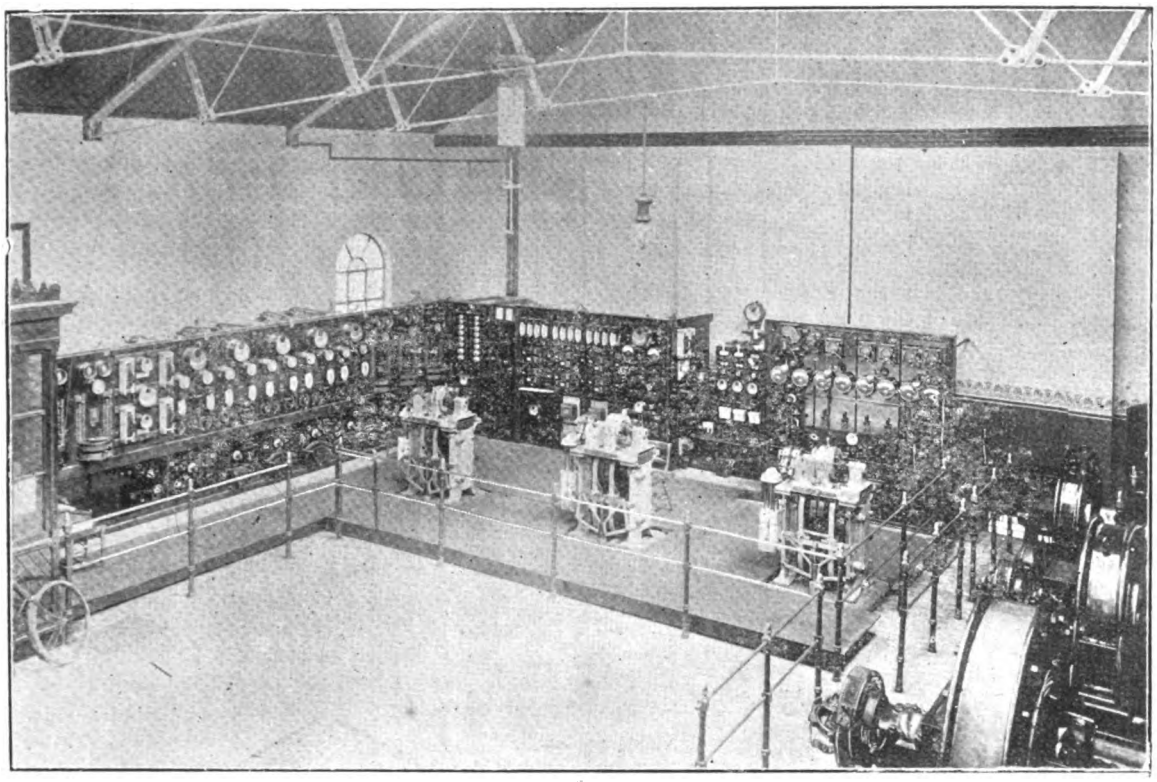

FIG 6.—Rectifiers and Switchboards.

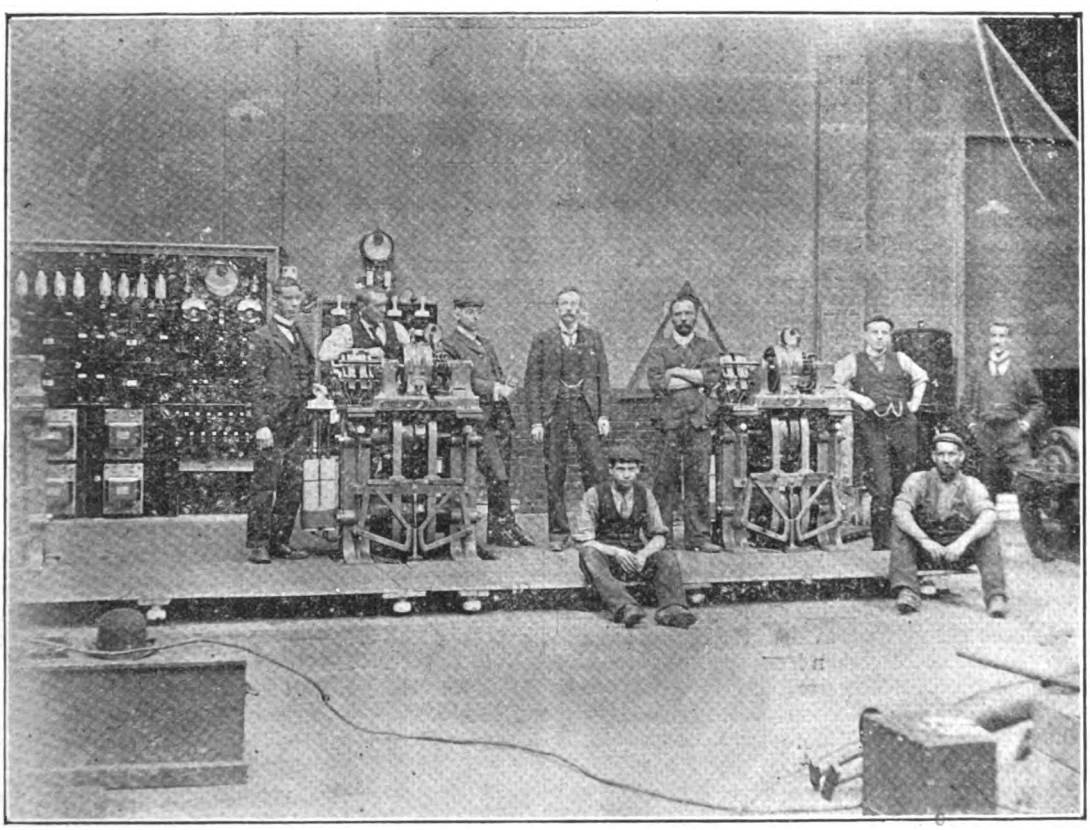

FIG 7.—Ferranti Rectifiers and Station Staff.

Digitized by Google

The next point in the report calling for notice is the changing over of the arc lighting system. This it was recommended should be done by introducing rectifiers, taking their supply from the high-voltage side of the alternate-current system. Here, again, an interesting comparison can be made between the old arc lighting plant, as illustrated in Fig. 2, and the new arc lighting plant, as seen in Fig. 6, in front of the switchboard, and which is again shown in Fig. 7, ornamented by the well-organised staff of the station. From this photograph it will be seen that the engineers at the Taunton electricity works are of as retiring a disposition as those in other parts of the country. The changing over of this arc lighting plant could not, however, be effected without a financial loss. The cost of the old plant was some £2,083, from which had to be deducted the depreciation and sinking fund, which brought the net value of the arc lighting plant on the Corporation books to £1,639. The actual value of the plant was only £500, and which is shown in Figs. 9 and 10, are wound with double-circuit dynamos and controlled by series-parallel controllers, so that they can be worked efficiently at widely varying speeds. Electric motors of the same type, but of a smaller size, are also used to drive the two boiler feed pumps, which were added at the same time as the condensing plant. These feed pumps are placed between the Babcock and Wilcox boilers and the Paxman "Economic" boilers, and are enclosed in a glazed room in order that the coal dust may not affect the workings of the bearings of the plant. There are now used for feeding the boilers two of these electrical pumps and one steam pump. The connections of steam and water pipes from these, and also the arrangements of the electrical conductors, provides against a complete breakdown of the boiler feed system from any one accident.

The mains at Taunton are worthy of notice from the fact that such a wide area is supplied as compared with

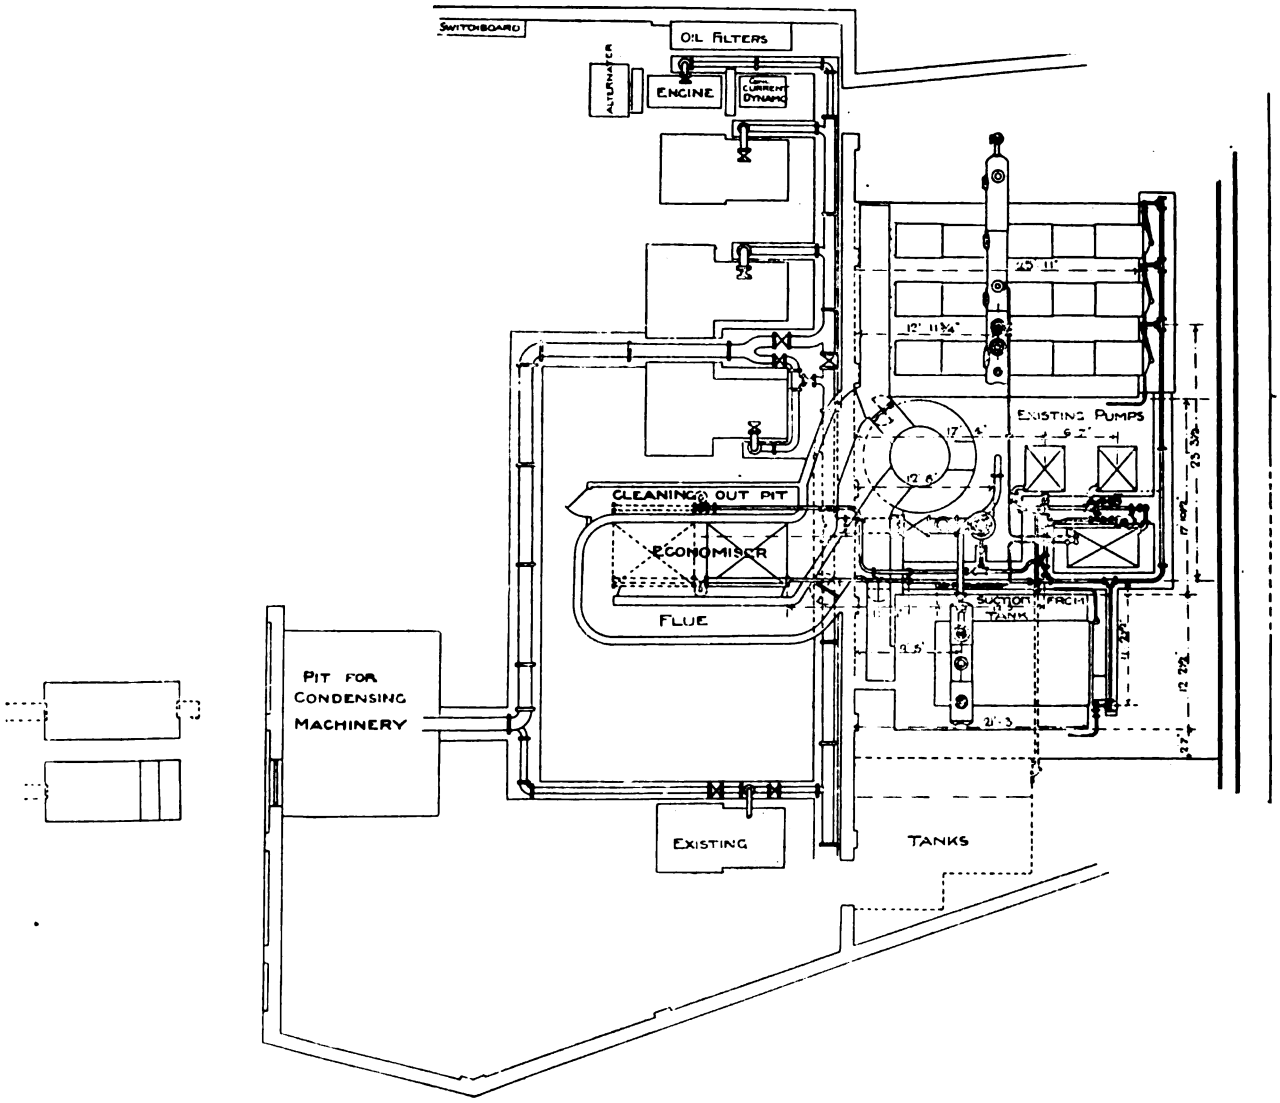

FIG. 8.—Plan of Taunton Electricity Works.

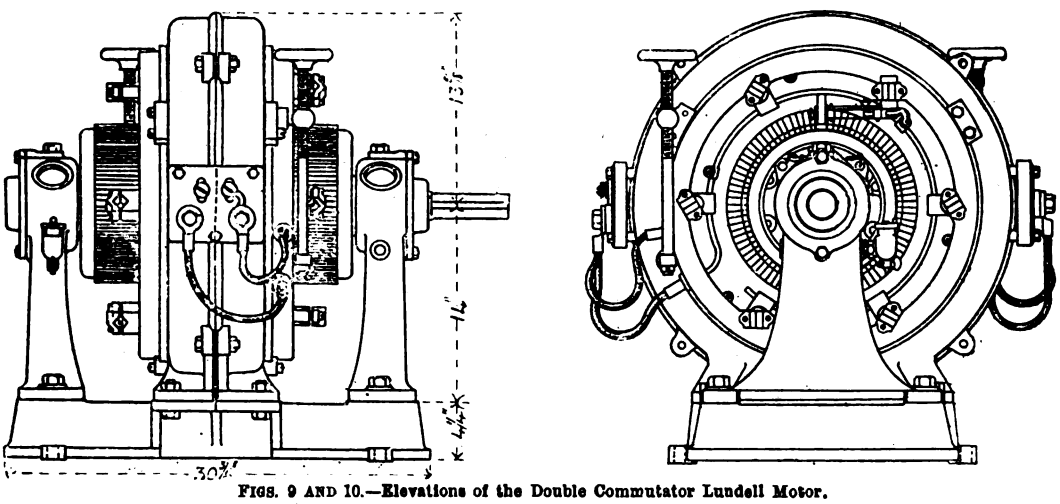
gave a loss of £1,139, which had to be provided out of revenue. The new rectifying plant was, however, installed, a loan of £550 being obtained from the Local Government Board for the purpose. This amount, together with the £500 obtained from the sale of the old plant, provided for the cost of the new, together with the £1,139 taken from revenue earned by the sale of electricity. The new arc lighting plant is able to supply 100 lamps alight at one time, leaving one rectifier as a spare, thus providing for 40 more lamps than could be supplied from the old plant. The great point, however, is that while the new arrangement is an exceedingly efficient one, the old one was the reverse. The result is shown by the coal-bill, to which we shall refer by-and-by. The complete plan of the works as reorganised is given in Fig. 8. A subsequent improvement to those mentioned above was the addition of the condensing plant, which is shown on this drawing, which consists of two jet condensers driven by two motors of the Lundell type. These motors, one of other towns in Great Britain of the same population. This wide-reaching supply shows that the Corporation has adopted the broad-minded policy of taking the mains to all probable consumers, and the result has quite justified the expenditure. Referring to the map of these mains (Fig. 11), the position of the central station is clearly marked. In this map we have denoted the routes of the high-tension mains by a single line, although, of course, in many cases more than one feeder is going down the road. Where low-tension distributing mains are being laid, we have cross-hatched the houses at either side of the street, so that the district served by these low-tension mains is clearly discernible. In other places the high-tension main is taken direct to a transformer on the consumer's premises. The main sub-station is situated under the municipal buildings, marked A, from which three $^{19}/_{14}$ triple-concentric feeders feed the ring main of $^{19}/_{14}$ concentric cable in the following streets: High-street, Fore-street (or round

Digitized by Google

the Parade), half of North-street, half of East-street. Mains branch off from this ring up the following streets: Mary-street, Paul-street, Hammet-street, Tower-street, and Castle-

main in the following streets: half of North-street, Bridge-street, North Town; also a feeder of $^{19}/_{14}$ runs back to the generating station, and supplies James-street and Cannon-



FIGS. 9 AND 10.—Elevations of the Double Commutator Lundell Motor.

green. Feeding points marked 1, 2, and 3. This sub-station has three 30-kw. transformers with earth shields, and the necessary double-pole high-tension and low-tension

street. Feeder points marked 4 and 5. In this sub-station are two 30-kw. transformers and a switchboard to control the same. The sub-station marked C on the map is situated

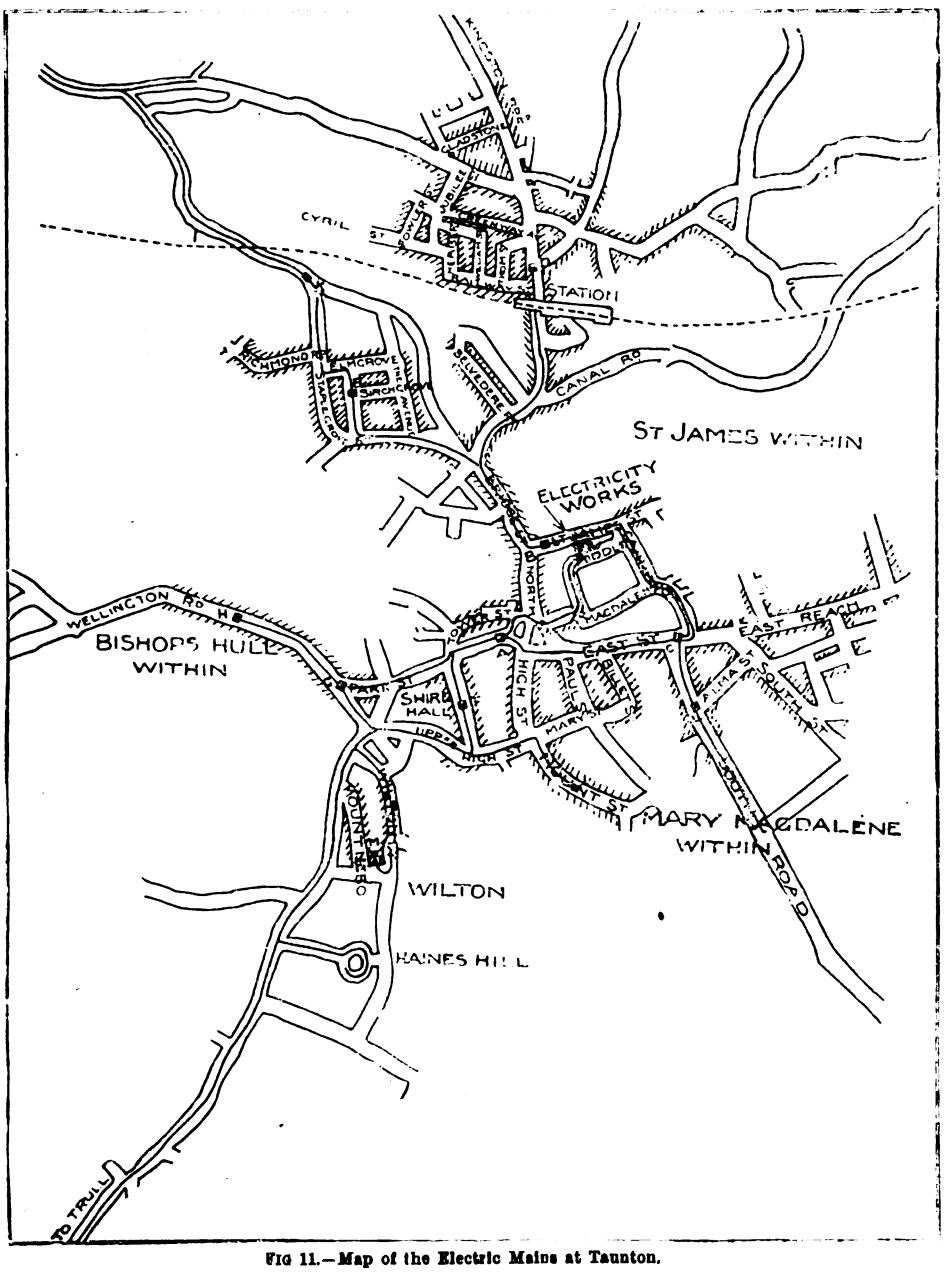


FIG 11.—Map of the Electric Mains at Taunton.

switches and fuses fixed on one board, with two ampere-meters and a voltmeter. The sub-station, marked B, in James-street has two feeders of $^{19}/_{14}$, which feed the ring

at the top of Tancred-street, and has five feeders of $^{19}/_{14}$ to the points marked 6, 7, 8, 9, and 10 on the ring of $^{19}{}_{14}$ supplying the several streets shown in Fig. 11. In

Digitized by Google

this sub-station there were two 30-kw. transformers and switchboard. The sub-station marked D is built under the pavement, and has been recently put down; consequently there are not yet many feeders in it, but pipes have been laid from Canal-road to Greenway-avenue, so that when the load increases on the sub-station feeders can easily be drawn through the pipes. In this station also there are two 30-kw. transformers and switchboard. The sub-station marked E, North Town, supplies a purely residential part of the town, and it has two 15-kw. transformers and switchboard in it. There are, besides the foregoing sub-stations, seven transformer pits which supply their own respective low-tension mains, with single transformers in them varying in size from 15 kw. to 1 kw. These are situated at the points marked F, G, H, I, K, L, and M. In every case where high-tension mains pass near one of the sub-stations, they are all taken into the same and tapped, so that it can be easy to give a supply in case of failure of any one feeder. On the switchboard in these sub-stations double-pole switches are provided, so that the load can be easily thrown over from one feeder to the other. In the transformer pits all the high-tension feeders are brought in through a box designed by the resident engineer, Mr. Thornhill, which contains Bates's high-tension fuses, and it is claimed that these high-tension fuses can be taken in or out, or the transformers switched off without doing any damage whatever to the gear or cables.

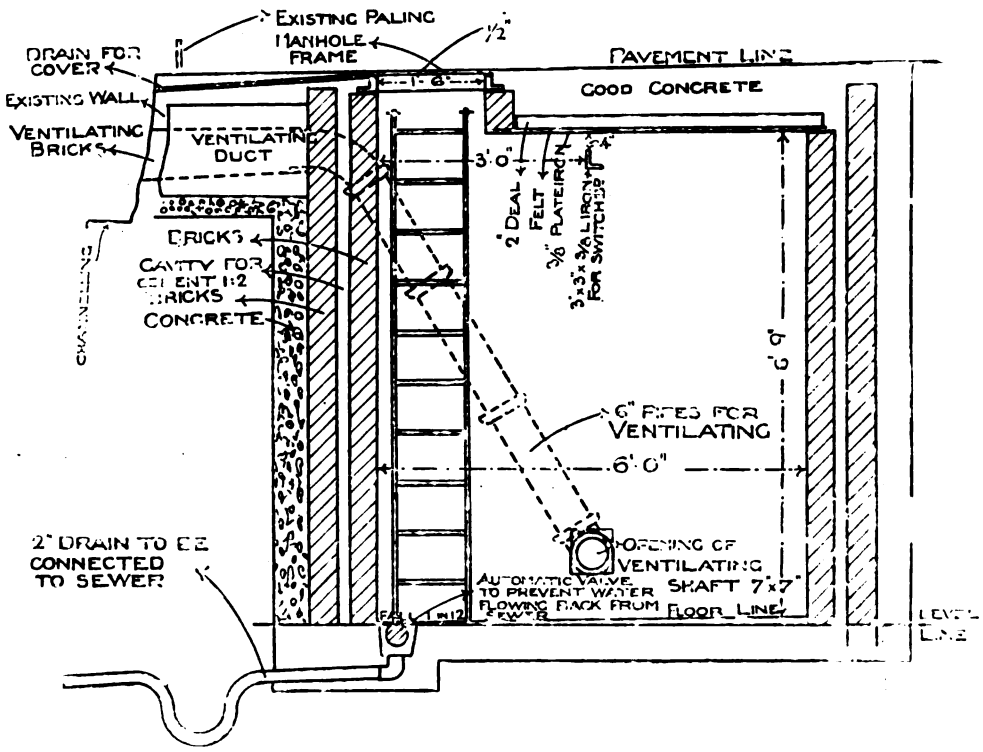

FIG. 12.—Section of Taunton Sub-Station.

An interesting feature in laying the distributing low-tension mains is that a house service box is provided for every fourth house at the time the mains are being laid. This throws on the original contractor the onus of making a good job of the service-box connections, and without doubt it is more easy for this to be done when the whole trench is opened up for laying the mains. The extra cost is not so much as one would expect, and it certainly facilitates the prompt connecting on of consumers. Fig. 12 is a section of one of the sub-stations, from which an idea of the ventilating and drainage arrangements adopted in Taunton for these sub-stations can be obtained.

FIG. 13.—Address Presented to Alderman Potter on the Opening of the Enterprise.

Digitized by Google

While the consulting engineers were reorganising the station, and the resident engineer was busy in keeping the supply in order in spite of the change over, it fell to the chairman of the Electric Lighting Committee to persuade his colleagues to spend the money, and also to provide the wherewith all for the undertaking. It is not fair to minimise the difficulty of this now that the undertaking has paid the one thousand and odd pounds out of revenue. The difficulty was in 1898 to persuade the rest of the members of the Corporation that this would be so; and we are pleased to see that when the new works were inaugurated last month the good work done by Alderman Potter was most suitably acknowledged by the presentation of an illuminated address and a service of plate. In Figs. 13 and 14 reproductions of photographs of both the address and the plate are given, which will give our readers some idea of the appreciation which is felt in Taunton of the good work done by Alderman Potter.

In a speech made at the opening ceremony, Alderman Potter referred to the fact that for a loan of practically £4,500 they had obtained a new plant with practically double the capacity of the old. They had also figures at their back to show that the change over from an obsolete plant to the new was financially right, in that it resulted in a great saving of coal. To illustrate this the following figures were given by Alderman Potter. In January, 1899, with the old plant the number of units generated in the station was 29,543, and the coal burned was 156 tons 13cwt. In January this year the units generated went up to 44,745, while the coal consumed was 156 tons 15cwt. This shows that for an increase of 50 per cent. in the units generated, the coal was only 2cwt. more. In view of the great rise in the price of coal, the change over was not made any too soon. The engineers are to be congratulated on the great coal economy effected with the new plant. As regards the progress of electric lighting at Taunton, it is interesting to note that when the Corporation took over the works there were only some 79 consumers connected to the mains, now there are nearly 600. In the same time the number of equivalent 8-c.p. lamps connected with the mains has increased from 1,840 up to nearly 17,000. Mr. Alderman Potter went on to say that many things had contributed to their success, not the least being the heads of the department themselves—Mr. Couzens, and now Mr. Thornhill. Notwithstanding what croakers might say as to the success of the undertaking, or men so steeped in financial ignorance as not to know that two and two made four, or so blinded by prejudice as not to see facts as clear as the noonday sun, it was a success, and a success unparalleled in the history of an electric light undertaking in any borough of its size in the kingdom. There was not another municipally conducted electric light undertaking in the kingdom of the size of Taunton that had ever produced such a satisfactory balance-sheet as that committee did last year.

We have to thank the consulting engineers, Alderman Potter, and Mr. Thornhill for the photographs, drawings, and information contained in this article.

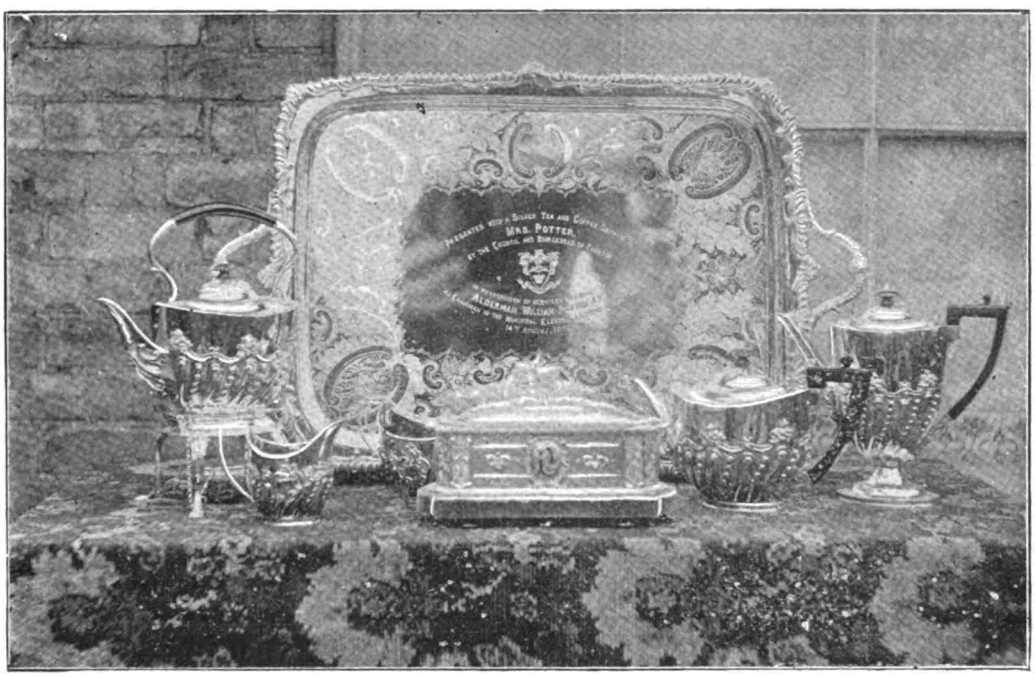

FIG. 14.—View of Plate Presented to Alderman Potter.

A COMBINATION INTEGRATING WATTMETER AND MAXIMUM-DEMAND INDICATOR.*

BY J. H. BARKER, M.I.E.E., A.M.I.C.E.

Before proceeding to describe the meter in question it is necessary to say a few words on maximum demand. It concerns engineers more especially, as every work they design or construct must be sufficiently strong to meet the greatest call which may ever be made upon it; their bridges strong enough to bear the heaviest train under the worst conditions of storm; their harbours deep enough to float the largest ship on the lowest tide. And of engineers, electricians suffer most: their plant must be sufficient to meet the maximum demand for light on any one night in the year. All their consumers need light at the same time, and Parliament says, rightly, they shall help themselves whenever they like. The result is shown in any supply station's daily record. A curve is given of that in Cambridge, taken on the heaviest day in the year, and on the same scale is shown the demand on the works if a regular amount could be generated every day. The actual requirement is 372 kw., the ideal 39 kw. (about one-ninth). Such an ideal is impossible until economic storage is more practicable than at present. However, the object of everyone in charge of a station should be to approach a little nearer the ideal state, for there is plenty of scope.

At present, electric lighting is undoubtedly more costly than gas. Consumers, as a rule, only light the more prominent parts of their houses and business premises electrically, which parts need light chiefly at the time of maximum demand, and for only one or two hours a day, using gas in basements, kitchens, and passages where light is needed for long hours, the very lights needed most by electricians to level up the hours of supply. It was evident that such lights could only be obtained if a reduced price were charged. But what is to be a fair charge? The late Dr. Hopkinson advocated a scheme that came very nearly to perfection in its idea; it was based on the fact that the

* Paper read before the British Association at Bradford.

Digitized by Google

cost of supplying each individual as regards capital outlay is proportional to his maximum demand for electricity, even though that maximum demand were only for a few minutes on one day in the year; this, therefore, should be taken as a basis for charging for the supply of current. It was further premised that unless a consumer used an amount of electricity equal to what he would have consumed were his maximum number of lamps burning for one hour per day, the supply authority could not be recouped at the statutory rate for their capital outlay and standing charges. Finally, when the consumer had received an amount of electricity equal to the above amount, he might be considered to have paid his share of interest on capital, and should be allowed to have his further supply at little more than the bare cost of production. To put this scheme into practice it is necessary to measure two quantities—the total amount of electricity used, and the maximum number of lamps or their equivalent ever lighted at one time. This system has been at work for some years with marked success, but it has been necessary to use two separate meters—one to integrate the total number of units consumed, and the second to record the maximum demand. Both meters absorb energy from the supply, to the detriment of the light. In conjunction with Prof. Ewing, the author has invented a meter which will combine the functions of the previous two. The external appearance is shown, and next is the explanation given to the consumer. The construction of the combined meter is shown; actual meters are on the table, and photographs are given on the screen. The maximum-demand device can be attached to meters of the magnetic brake type, a prominent example of which is the meter sold by the Thomson-Houston Company, Limited.

The meter is essentially a motor and a magnetic brake. The latter consists of a copper disc revolving in a horizontal plane between the poles of two permanent magnets; the magnets set up eddy currents in the disc and produce a drag which is proportional to the speed of the rotation. In carrying out the invention this drag is made use of. The two magnets are supported on a beam and suspended in such a manner that they tend to follow the rotation of the disc; a section of the suspension is shown. A steel wire enclosed within a tube is fixed at its upper end to a screw; at its lower extremity it is secured to the beam itself. The torsion of the steel wire acts as a spring and controls the distance through which the suspended system moves. The spring or other controlling force is made comparatively strong in order that the motion of the magnet poles may be so small as not to affect the rate of the meter, and also in order that the period of oscillation of the suspended system may be short. When a sudden increase takes place in the demand for current, and consequently in the rate of supply, the magnetic brake would tend to swing beyond the position proper to the new rate of supply if its period of oscillation were not short in relation to the time taken by the revolving parts of the meter to acquire their new velocity. This tendency is obviated by making the period of oscillation of the brake sufficiently short in relation to the time during which the disc is undergoing acceleration when the current is suddenly applied or suddenly increased. Further advantages of the strong controlling force, and consequently small movement of the brake, are that the brake may be pivoted eccentrically to the disc without causing its motion to affect the rate of the meter, and also that there is no necessity for the use of a dashpot or similar arrangement to check the oscillations, although such means may be used if desired. Again, the small motion of the brake assists in preventing disturbance of the indications through the direct effect of the motor coils in cases where continuous currents are used and the field of the motor is produced by currents in coils. The motion of the brake is multiplied and actuates the indicator as shown. A light ratchet and pawl is fixed at one end of the beam and retains the system at its point of maximum deflection. A lever with a sealing device passes through the outside of the case, and enables the meter inspector to reset the indicator at the end of each quarter or half year, as the case may be. In meters for measuring supply by continuous currents, care must be taken to arrange the magnetic brake so that the electric currents in the meter do not directly tend to displace it. For this purpose it is preferable to invert one of the two magnets forming the brake so that the pair shall constitute an astatic or nearly astatic system. When this is done, it may in some cases occur that the stray field from the magnets constituting the brake affects the field of the motor, and consequently disturbs the rate of the meter. This may be compensated for by several devices, such as introducing a separate compensating magnet to balance on the motor armature the field produced by the magnets of the brake, or using a shunt field coil in the motor for the same purpose. The scales for all sizes of meters are made the same, and the readings follow a straight-line law; the adjustment for rate is shown. The divisions of the scale are given in percentages of full load of the meter, and a table is fixed to the front of each case, giving at a glance the maximum demand corresponding to any reading, as well as the number of units which must be consumed before the lower rate is charged.

Next there is shown a meter adapted for use on a switchboard. It integrates the amount of current which has passed through any feeder or from any dynamo, and informs the attendant the quantity passing through at any moment, obviating the use of an ammeter, more properly speaking, a wattmeter. It differs from the ordinary meter, inasmuch as it has no ratchet and pawl, and is free to return to its zero position on the stoppage of current through the instrument.

There are many advantages claimed for this form of demand indicator: (*a*) it combines in one instrument the dual function of integrating and of recording the maximum demand; (*b*) as an indicator it absorbs no energy from the supply; (*c*) it contains no liquid or injurious acid; (*d*) it is not affected by any ordinary short-circuit; (*e*) it records alternating or direct current (in the case of alternating current it records true watts and not apparent watts, an important item in respect of supply to motors and arc lamps); (*f*) it is extremely accurate (a curve at varying loads is shown).

Mr. Reginald P. Wilson, of 66, Victoria-street, some few years ago devised a maximum-demand indicator embodying the same principle. A model of his meter is shown, and a diagram giving the working of the same. The difficulty in this form was that the swing of the suspended system was sufficient to carry the pointer beyond its correct reading if a larger amount of current than a very small fraction of its full load were switched on at any one time, and the meter was never in commercial use. The inventors of the Barker and Ewing meter were unaware of Wilson's patent until their own was in its final form. They have, however, acquired this patent.

ADDENDUM.

The following is a copy of the circular sent out with all meters fixed on consumers' premises by the Cambridge Electric Supply Company:

"*Explanation to Consumers.*

"The meter records on four small dials the total number of units of electricity consumed, in the same manner as a gasmeter. The indicating pointer shows on a scale the greatest rate at which electricity has been supplied corresponding to the largest number of lamps which have been lighted at once. The company calls this latter the maximum demand. If this largest number of lamps had been burning for one hour every day during the six months, they would have consumed a certain number of units, and for that number of units, or for any less number of units which may have been consumed, the company charges full price per unit. If the consumer has used a greater number of units, he is charged a lower rate for all the units used over and above the number which would have been used had the largest number of lamps lighted at one time burned for one hour every day during the six months."

Sick Clubs.—The whole of the men in the electric light department of the Eastbourne Town Council have been informed that unless they join the Corporation sick club they will not be entitled to any sick pay.

A NEW FORM OF CALORIMETER FOR MEASURING THE WETNESS OF STEAM.*

BY PROF. JOHN GOODMAN, M.I.C.E.

It is no uncommon thing at the present day for purchasers of steam-engines to specify the steam consumption per horse-power hour, and to add penalty clauses for a higher consumption than that specified, but it is quite impossible to accurately measure the *steam* consumption of the engine unless the amount of moisture in it be known. If the moisture be neglected, the makers of the engine run a great risk of being unduly penalised. Some Continental steam-engine makers who have a high reputation for economy in steam consumption owe an appreciable amount of that reputation to the fact that they always specify the steam consumption in terms of an equivalent amount of "dry steam," and British makers have, in some instances, lost orders through not appreciating this point, their engines giving practically the same result as the Continental engines when compared on the "dry steam" basis, but they do not show up to advantage when the results of the British engine are expressed as so many pounds of steam—probably wet—per horse-power hour, while the results of the Continental engine are reduced to pounds of "dry steam" per horse-power hour. With certain types of boilers which are not forced, and which are provided with well-clothed steam-pipes, the amount of moisture may not exceed 2 or 3 per cent.; but in very many instances the steam that reaches the engine is far wetter than this. Some types of boilers are greatly puffed by their makers for their apparent economy in evaporation, but their reputation is based on certain tests which have simply shown that a large weight of water has passed through the boiler per pound of fuel consumed. The water has been assumed to be all evaporated, but if the wetness of the steam had been measured a very different tale would have to be told, because much of the water leaves the boiler as priming water, and not as steam. The necessity of measuring the wetness of the steam may therefore be great in cases in which it is important to know accurately what a given engine or boiler is doing as regards steam.

The two most common methods in use which have any pretence to accuracy of measuring the wetness of steam are by (1) the throttling or wire-drawing calorimeter, in which the wetness is indirectly obtained by measuring the quantity of heat required to superheat the steam; (2) the continuous condensing calorimeter, in which a known weight of steam is mixed with a known weight of cold water, the wetness being calculated from the resulting temperature of the mixture.

The first-mentioned—viz., the wire-drawing calorimeter—has recently received a rude shock, which almost places it out of the field, for with this type of instrument the all-important factor—viz., the specific heat of superheated steam—was, until recently, assumed to be constant—viz., 0·48; but the recent experiments of Mr. Grindley, of Manchester, have shown that it is not even approximately constant: it varies from 0·4 to 0·68, and, unfortunately for users of wire-drawing calorimeters, it does not follow any simple or even any ascertained definite law. Thus, wetness determinations by such an instrument may be very misleading.

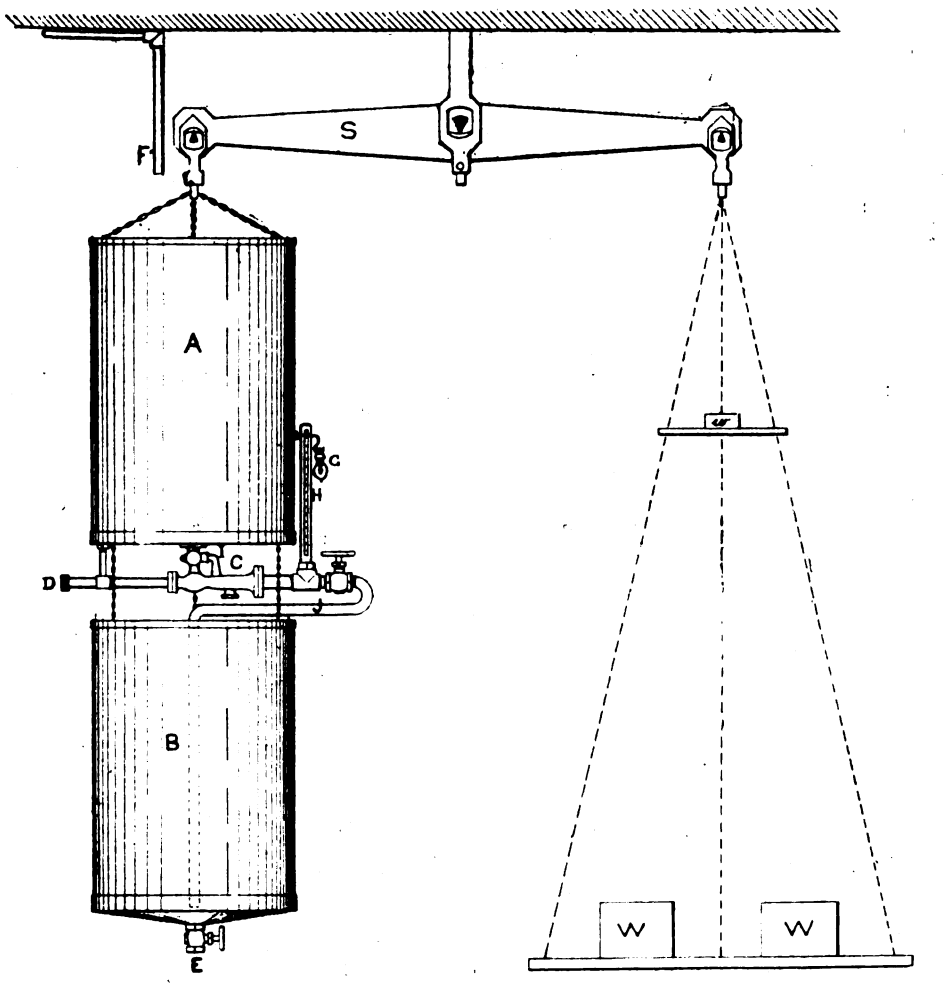

FIG. 1.

Several continuous condensing calorimeters have been used with success, but they are generally cumbersome and expensive, because they require two exceptionally good weighing machines. In the new form of instrument designed by the author, the weighing is done on one scale beam, thus making the instrument much more portable, cheaper, and more accurate, because a smaller difference in weight can be detected than in the case of instruments which depend on weighing machines. It consists of a scale beam, S, about 3ft. 6in. in length (Fig. 1), which will turn with $\frac{1}{100}$th of a pound when weighing 120lb. Two cylindrical tanks, A and B, 16in. diameter and 24in. high, are suspended by three light chains from the scale-beam

* Paper read before the British Association at Bradford.

Digitized by Google

hook. A small mixing injector, C, is attached to the bottom of the tank, A, through which the cold water from the top tank passes, and is there mixed with the steam, which is supplied by a removable flexible steam-pipe attached at D, which is thoroughly clothed for convenience in handling and for preventing radiation. The mixed steam and water pass a thermometer, H, with a naked bulb, on its way through the pipe, J, to the lower tank, B. An outlet cock, E, enables the lower tank, B, to be emptied at will. The bottom of this tank should be dished, in order to allow the water to drain out. A double scale pan is suspended from the other end of the scale beam; the small upper one is for steam weights and the lower one for water weights. The object of using the two pans is to prevent mistakes when weighing the two quantities separately.

The method of using the instrument is as follows: The tank A is filled with water from a pipe, F, until it just counterbalances the weight, W_1, in the large scale pan—usually two standard 56lb. weights. The temperature, t_1, of the water in A is then measured to the nearest one-tenth of a degree by a Kew certified thermometer. For very accurate tests it is better to allow the water to remain in A for some time before it is used in order to allow it to reach approximately the temperature of the room, or, if necessary, some warm water may be mixed with the cold for the same purpose. This precaution is for the sake of avoiding errors due to conduction and radiation. The incandescent lamp, G, is then suspended from a hook provided for the purpose, to enable the thermometer, H, to be seen clearly. The steam-pipe, D, after thoroughly blowing through, is then coupled up, and at a given signal both the steam-supply valve and the water-cock, I, on the injector are opened; the water from the tank A then runs into the injector and mixes with the steam; the mixture is delivered through the pipe, J, to the bottom of the tank B. The instant the above-mentioned valves are opened, an observer begins to take readings of the outlet temperature at H at every 10 or 15 seconds. For this purpose a centre-seconds watch is hung from a hook close to the thermometer. The experiment is continued until the tank A is nearly empty, which usually takes about five minutes. Then at a given signal both the steam and water valves are shut off at the same instant, the flexible steam-pipe is uncoupled, and the incandescent lamp removed. The whole apparatus is again balanced up by placing small weights, w, on the top scale pan, which represent the weight of steam that has been mixed with the water. They are left in position, and the tank B is emptied by means of the cock, E. When all the water has drained out, the apparatus is balanced up for the third time by the weights, W_2, on the large scale pan. The weight of the water which has been mixed with the steam is then $W = W_1 - W_2$.

The steam pressure having been noted during the test, we now have all the data we need for calculating the "dryness fraction," x, of the steam. If L be the latent heat of the steam, and t its temperature, and t_2 the mean outlet temperature as obtained from the thermometer, H, we have

$$(x\,L + t - t_2)\,w = W\,(t_2 - t_1),$$

whence

$$x = \frac{\frac{W}{w}(t_2 - t_1) + t_2 - t}{L}.$$

The possible sources of error in an instrument of this type are:

1. *Errors in Weighing the Quantities of Steam and Water.*—With care these need not exceed $\frac{1}{100}$th of a pound, or about 0·1 per cent. in the quality of the steam.

2. *Errors in Measuring the Temperature of the Water.*—The thermometers can be read to within one-tenth of a degree, and if the errors in reading be not greater than that, it will produce an error of about 0·13 per cent. in the final result. There is no difficulty in getting the initial temperature to this degree of accuracy, but the final or outlet temperature is not so certain, because it is very difficult to get a true reading at the instant of starting, as it takes a few seconds to get a steady flow from the injector. The error, however, cannot be serious, because there is only one uncertain reading out of about 30. It is for the sake of minimising this error that readings of the outlet thermometer are taken every 10 or 15 seconds. The mean of all the readings are taken as the t_2 in the formula given above. A rough check on the outlet temperature is obtained by taking the temperature in the bottom tank, B; it is too low on account of radiation and due to the water imparting some of its heat to the tank itself. The difference between the two methods, after the tank has got warmed up by the first experiment, varies from 0·6deg. to 1·0deg. F. If it be much more than that, it is a sure sign that some mistake has occurred in reading the thermometer, H. The object of placing the thermometer, H, close to the injector is to avoid radiation errors.

3. *Error in Measuring the Steam Pressure.*—This, of course, may be reduced to any extent we please by using a good form of pressure gauge. The final result will be in error to the extent of about 0·25 per cent. if the pressure be incorrectly obtained to the extent of 5lb. per square inch. The pressure gauge should preferably be placed in direct communication with the steam-pipe itself, rather than trust to the boiler pressure gauge.

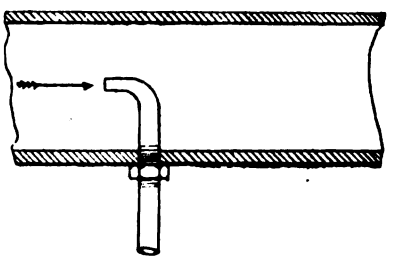

FIG. 2.

4. *Errors Due to Getting an Unfair Sample of Steam from the Steam-Pipe.*—It is believed that the above-mentioned errors of observation and of the instrument itself are very small and negligible as compared with the possible errors of sampling. There is a great difference of opinion as to how the steam should be sampled. Some take it by means of a bent nozzle (Fig. 2) facing the flowing steam, and made with such an area of opening that the speed of flow of the steam through it shall be equal to that of the steam in the main pipe from which the sample is taken. Others, however, prefer a horizontal perforated pipe passing diametrically across a horizontal main steam-pipe (Fig. 3). The author ventures to think that both are defective, because they make no attempt to catch the priming water, which necessarily runs along the bottom of a horizontal steam-pipe. It is evident that both of the above-mentioned methods of sampling only catch that moisture which exists in the steam as "Scotch mist" or fine rain. It is considered that a vertical perforated pipe (Fig. 4) passing upwards through the bottom of the pipe gives a far fairer sample. Care should be taken to have one hole so arranged that priming water running along the bottom of the pipe will be caught by the sampling pipe. It is practically impossible, however, to ensure a fair sample by means of a sampling pipe, and whichever method one adopts, it is largely a matter of opinion as to whether it is an approximately fair sample or not.

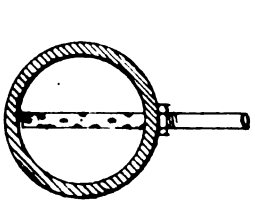

FIG. 3.

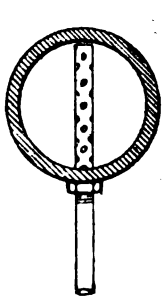

FIG. 4.

The following instance of a test may be of interest. Some stationary boilers were under test, and were known to be priming very seriously, because the engine-driver was obliged to keep his cylinder drain-cocks full open during the whole of the time he was running, although the steam-pipes were clothed and were not abnormally

Digitized by Google

long. A further proof that the steam was very wet was that water dripped, almost ran, out of every joint along the steam-pipe; no steam escaped, hence one cannot say that the joints were seriously at fault. Three sampling pipes were put in for testing the steam. In one case the sample was taken by a vertical sampling pipe at the low end of a nearly horizontal length of pipe near the steam-chest. The moisture present was over 40 per cent. Another vertical sampling pipe was put in a horizontal length of steam-pipe close to the boilers. The quantity of moisture was found to be 19 per cent.; a horizontal sampling pipe close to the last-named gave 2 per cent. The difference was, of course, due to the priming water not being caught at all in the horizontal sampling pipe. The very abnormal result obtained near the engine was probably due to water collecting in the main just where the sampling pipe was inserted. The instrument, weights, and thermometers were checked the next day and found to be correct; the instrument was also checked by coupling it up to a steam-pipe in the college, in which the wetness is known with a fair degree of accuracy from constant tests made whenever an engine trial is made. The author is of the opinion that steam calorimeters may be checked for accuracy by taking a sample of steam from a vertical steam-pipe immediately over a boiler from which no steam is flowing beyond that required for the sample. Such steam is certainly dry, and therefore the instrument should show $x = 1$.

The instrument described is not protected in any way, and the author will be glad to give the benefit of his experience to anyone contemplating the making of a similar instrument.

THE BRITISH ASSOCIATION.

Address to the Mathematical and Physical Section

BY JOSEPH LARMOR, M.A., D.SC., F.R.S., PRES.C P.S.,
PRESIDENT OF THE SECTION.

It is fitting that before entering upon the business of the section we should pause to take note of the losses which our department of science has recently sustained. The fame of Bertrand, apart from his official position as secretary of the French Academy of Sciences, was long ago universally established by his classical treatise on the infinitesimal calculus: it has been of late years sustained by the luminous exposition and searching criticism of his books on the theory of probability and thermodynamics and electricity. The debt which we owe to that other veteran, G. Wiedemann, both on account of his own researches, which take us back to the modern revival of experimental physics, and for his great and indispensable thesaurus of the science of electricity, cannot easily be overstated. By the death of Sophus Lie, following soon after his return to a chair in his native country Norway, we have lost one of the great constructive mathematicians of the century, who has in various directions fundamentally expanded the methods and conceptions of analysis by reverting to the fountain of direct geometrical intuition. In Italy the death of Beltrami has removed an investigator whose influence has been equally marked on the theories of transcendental geometry and on the progress of mathematical physics. In our own country we have lost in D. E. Hughes one of the great scientific inventors of the age; while we specially deplore the removal, in his early prime, of one who has recently been well known at these meetings, Thomas Preston, whose experimental investigations on the relations between magnetism and light, combined with his great powers of lucid exposition, marked out for him a brilliant future.

Perhaps the most important event of general scientific interest during the past year has been the definite undertaking of the great task of the international co-ordination of scientific literature; and it may be in some measure in the prolonged conferences that were necessitated by that object that the recently announced international federation of scientific academies has had its origin. In the important task of rendering accessible the stores of scientific knowledge, the British Association, and in particular this section of it, has played the part of pioneer. Our annual volumes have long been classical, through the splendid reports of the progress of the different branches of knowledge that have been from time to time contributed to them by the foremost British men of science; and our work in this direction has received the compliment of successful imitation by the sister associations on the Continent.

The usual conferences connected with our department of scientific activity have been this year notably augmented by the very successful international congresses of mathematicians and of physicists which met a few weeks ago in Paris. The three volumes of reports on the progress of physical science during the last 10 years, for which we are indebted to the initiative of the French Physical Society, will provide an admirable conspectus of the present trend of activity, and form a permanent record for the history of our subject.

Another very powerful auxiliary to progress is now being rapidly provided by the republication, in suitable form and within reasonable time, of the collected works of the masters of our science. We have quite recently received, in a large quarto volume, the mass of most important unpublished work that was left behind him by the late Prof. J. C. Adams; the zealous care of Prof. Sampson has worked up into order the more purely astronomical part of the volume; while the great undertaking, spread over many years, of the complete determination of the secular change of the magnetic condition of the earth, for which the practical preparations had been set on foot by Gauss himself, has been prepared for the press by Prof. W. G. Adams. By the publication of the first volume of Lord Rayleigh's papers a series of memoirs which have formed a main stimulus to the progress of mathematical physics in this country during the past 20 years has become generally accessible. The completed series will form a landmark for the end of the century that may be compared with Young's "Lectures on Natural Philosophy" for its beginning.

The recent reconstruction of the University of London, and the foundation of the University of Birmingham, will, it is to be hoped, give greater freedom to the work of our university colleges. The system of examinations has formed an admirable stimulus to the effective acquisition of that general knowledge which is a necessary part of all education. So long as the examiner recognises that his function is a responsible and influential one, which is to be taken seriously from the point of view of moulding the teaching in places where external guidance is helpful, test by examination will remain a most valuable means of extending the area of higher education. Except for workers in rapidly progressive branches of technical science, a broad education seems better adapted to the purposes of life than special training over a narrow range; and it is difficult to see how a reasonably elastic examination test can be considered as a hardship. But the case is changed when preparation for a specialised scientific profession, or mastery of the lines of attack in an unsolved problem, is the object. The general education has then been presumably finished; in expanding departments of knowledge, variety rather than uniformity of training should be the aim, and the genius of a great teacher should be allowed free play without external trammels. It would appear that in this country we have recently been liable to unduly mix up two methods. We have been starting students on the special and lengthy, though very instructive, processes which are known as original research at an age when their time would be more profitably employed in rapidly acquiring a broad basis of knowledge. As a result, we have been extending the examination test from the general knowledge to which it is admirably suited into the specialised activity which is best left to the stimulus of personal interest. Informal contact with competent advisers, themselves imbued with the scientific spirit, who can point the way towards direct appreciation of the works of the masters of the science, is far more effective than detailed instruction at second hand, as regards growing subjects that have not yet taken on an authoritative form of exposition. Fortunately, there seems to be now no lack of such teachers to meet the requirements of the technical colleges that are being established throughout the country.

The famous treatise which opened the modern era by treating magnetism and electricity on a scientific basis appeared just 300 years ago. The author, William Gilbert, M.D., of Colchester, passed from the grammar school of his native town to St. John's College, Cambridge; soon after taking his first degree, in 1560, he become a Fellow of the college, and seems to have remained in residence and taken part in its affairs for about 10 years. All through his subsequent career, both at Colchester and afterwards at London, where he attained the highest position in his profession, he was an exact and diligent explorer, first of chemical and then of magnetic and electric phenomena. In the words of the historian Hallam, writing in 1839, "in his Latin treatise on the magnet he not only collected all the knowledge which others had possessed, but he became at once the father of experimental philosophy in this island," and no demur would be raised if Hallam's restriction to this country were removed. Working nearly a century before the time when the astronomical discoveries of Newton had originated the idea of attraction at a distance, he established a complete formulation of the interaction of magnets by what we now call the exploration of their fields of force. His analysis of the facts of magnetic influence, and incidentally of the points in which it differs from electric influence, is virtually the one which Faraday reintroduced. A cardinal advance was achieved at a time when the Copernican astronomy had still largely to make

Digitized by Google

its way, by assigning the behaviour of the compass and the dip needle to the fact that the earth itself is a great magnet, by whose field of influence they are controlled. His book passed through many editions on the Continent within 40 years; it won the high praise of Galileo. Gilbert has been called "the father of modern electricity" by Priestley, and the "Galileo of magnetism" by Poggendorff.

When the British Association last met at Bradford in 1873, the modern theory which largely reverts to Gilbert's way of formulation, and refers electric and magnetic phenomena to the activity of the æther instead of attractions at a distance, was of recent growth: it had received its classical exposition only two years before by the publication of Clerk Maxwell's treatise. The new doctrine was already widely received in England on its own independent merits. On the Continent it was engaging the strenuous attention of Helmholtz, whose series of memoirs, deeply probing the new ideas in their relation to the prevalent and fairly successful theories of direct action across space, had begun to appear in 1870. During many years the search for crucial experiments that would go beyond the results equally explained by both views met with small success; it was not until 1887 that Hertz, by the discovery of the æthereal radiation of long wave-length emitted from electric oscillators, verified the hypothesis of Faraday and Maxwell, and initiated a new era in the practical development of physical science. The experimental field thus opened up was soon fully occupied both in this country and abroad; and the borderland between the sciences of optics and electricity is now being rapidly explored. The extension of experimental knowledge was simultaneous with increased attention to directness of explanation; the expositions of Heaviside and Hertz and other writers fixed attention, in a manner already briefly exemplified by Maxwell himself, on the inherent simplicity of the completed æthereal scheme, when once the theoretical scaffolding employed in its construction and dynamical consolidation is removed; while Poynting's beautiful corollary specifying the path of the transmission of energy through the æther has brought the theory into simple relations with the applications of electro-dynamics.

Equally striking has been the great mastery obtained during the last 20 years over the practical manipulation of electric power. The installation of electric wires as the nerves connecting different regions of the earth had attained the rank of accomplished fact so long ago as 1857, when the first Atlantic cable was laid. It was largely the theoretical and practical difficulties, many of them unforeseen, encountered in carrying that great undertaking to a successful issue that necessitated the elaboration by Lord Kelvin and his coadjutors of convenient methods and instruments for the exact measurement of electric quantities, and thus prepared the foundation for the more recent practical developments in other directions. On the other hand, the methods of theoretical explanation have been in turn improved and simplified through the new ways of considering the phenomena which have been evolved in the course of practical advances on a large scale, such as the improvement of dynamo armatures, the conception and utilisation of magnetic circuits, and the transmission of power by alternating currents. In our time the relations of civilised life have been already perhaps more profoundly altered than ever before, owing to the establishment of practically instantaneous electric communication between all parts of the world. The employment of the same subtle agency is now rapidly superseding the artificial reciprocating engines and other contrivances for the manipulation of mechanical power that were introduced with the employment of steam. The possibilities of transmitting power to great distances at enormous tension, and therefore with very slight waste, along lines merely suspended in the air, are being practically realised; and the advantages thence derived are increased manifold by the almost automatic manner in which the electric power can be transformed into mechanical rotation at the very point where it is desired to apply it. The energy is transmitted at such lightning speed that at a given instant only an exceedingly minute portion of it is in actual transit. When the tension of the alternations is high, the amount of electricity that has to oscillate backwards and forwards on the guiding wires is proportionately diminished, and the frictional waste reduced. At the terminals the direct transmission from one armature of the motor to the other, across the intervening empty space, at once takes us beyond the province of the pushing and rubbing contacts that are unavoidable in mechanical transmission; while the perfect symmetry and reversibility of the arrangement by which power is delivered from a rotatory alternator at one end, guided by the wires to another place many miles away, where it is absorbed by another alternator with precise reversal of the initial stages, makes this process of distribution of energy resemble the automatic operations of nature rather than the imperfect material connections previously in use. We are here dealing primarily with the flawless continuous medium which is the transmitter of radiant energy across the celestial spaces; the part played by the coarsely constituted material conductor is only that of a more or less imperfect guide which directs the current of æthereal energy. The wonderful nature of this theoretically perfect, though of course practically only approximate, method of abolishing limitations of locality with regard to mechanical power is not diminished by the circumstance that its principle must have been in some manner present to the mind of the first person who fully realised the character of the reversibility of a Gramme armature.

In theoretical knowledge a new domain, to which the theory as expounded 20 years ago had little to say, has recently been acquired through the experimental scrutiny of the electric discharge in rarefied gaseous media. The very varied electric phenomena of vacuum tubes, whose electrolytic character was first practically established by Schuster, have been largely reduced to order through the employment of the high exhaustions introduced and first utilised by Crookes. Their study under these circumstances, in which the material molecules are so sparsely distributed as but rarely to interfere with each other, has conduced to enlarged knowledge and verification of the fundamental relations in which the individual molecules stand to all electric phenomena, culminating recently in the actual determination, by J. J. Thomson and others following in his track, of the masses and velocities of the particles that carry the electric discharge across the exhausted space. The recent investigations of the circumstances of the electric dissociation produced in the atmosphere and in other gases by ultra-violet light, the Röntgen radiation, and other agencies, constitute one of the most striking developments in experimental molecular physics since Graham determined the molecular relations of gaseous diffusion and transpiration more than half a century ago. This advance in experimental knowledge of molecular phenomena, assisted by the discovery of the precise and rational effect of magnetism on the spectrum, has brought into prominence a modification or rather development of Maxwell's exposition of electric theory, which was dictated primarily by the requirements of the abstract theory itself; the atoms or ions are now definitely introduced as the carriers of those electric charges which interact across the æther, and so produce the electric fields whose transformations were the main subject of the original theory.

We are thus inevitably led, in electric and æthereal theory, as in the chemistry and dynamics of the gaseous state, which is the department of abstract physics next in order of simplicity, to the consideration of the individual molecules of matter. The theoretical problems which had come clearly into view a quarter of a century ago, under Maxwell's lead, whether in the exact dynamical relations of æthereal transmission or in the more fortuitous domain of the statistics of interacting molecules, are those around which attention is still mainly concentrated; but as the result of the progress in each, they are now tending towards consolidation into one subject. I propose—leaving further review of the scientific aspect of the recent enormous development of the applications of physical science for hands more competent to deal with the practical side of that subject—to offer some remarks on the scope and validity of this molecular order of ideas, to which the trend of physical explanation and development is now setting in so pronounced a manner.

If it is necessary to offer an apology for detaining the attention of the section on so abstract a topic, I can plead its intrinsic philosophical importance. The hesitation so long felt on the Continent in regard to discarding the highly developed theories which analysed all physical actions into direct attractions between the separate elements of the bodies concerned, in favour of a new method in which our ideas are carried into regions deeper than the phenomena, has now given place to eager discussion of the potentialities of the new standpoint. There has even appeared a disposition to consider that the Newtonian dynamical principles, which have formed the basis of physical explanation for nearly two centuries, must be replaced in these deeper subjects by a method of direct description of the mere course of phenomena, apart from any attempt to establish causal relations; the initiation of this method being traced, like that of the Newtonian dynamics itself, to this country. The question has arisen as to how far the new methods of æthereal physics are to be considered as an independent departure, how far they form the natural development of existing dynamical science. In England, whence the innovation came, it is the more conservative position that has all along been occupied. Maxwell was himself trained in the school of physics established in this country by Sir George Stokes and Lord Kelvin, in which the dominating idea has been that of the strictly dynamical foundation of all physical action. Although the pupil's imagination bridged over dynamical chasms, across which the master was not always able to follow, yet the most striking feature of Maxwell's scheme was still the dynamical framework into which it was built. The more advanced reformers have now thrown overboard the apparatus of potential functions which Maxwell found necessary for the dynamical consolidation of his theory, retaining only the final result as a verified descriptive basis for the phenomena. In this way all difficulties relating to dynamical development and, indeed, consistency are avoided, but the question remains as to how much is thereby lost. In practical electromagnetics the transmission of power is now the most prominent phenomenon;

Digitized by Google

if formal dynamics is put aside in the general theory, its guidance must here be replaced by some more empirical and tentative method of describing the course of the transmission and transformation of mechanical energy in the system.

The direct recognition in some form, either explicitly or tacitly, of the part played by the æther has become indispensable to the development and exposition of general physics ever since the discoveries of Hertz left no further room for doubt that this physical scheme of Maxwell was not merely a brilliant speculation, but constituted, in spite of outstanding gaps and difficulties, a real formulation of the underlying unity in physical dynamics. The domain of abstract physics is, in fact, roughly divisible into two regions. In one of them we are mainly concerned with interactions between one portion of matter and another portion occupying a different position in space; such interactions have very uniform and comparatively simple relations; and the reason is traceable to the simple and uniform constitution of the intervening medium in which they have their seat. The other province is that in which the distribution of the material molecules comes into account. Setting aside the ordinary dynamics of matter in bulk, which is founded on the uniformity of the properties of the bodies concerned and their experimental determination, we must assign to this region all phenomena which are concerned with the uncoordinated motions of the molecules, including the range of thermal and in part of radiant actions; the only possible basis for detailed theory is the statistical dynamics of the distribution of the molecules. The far more deep-seated and mysterious processes which are involved in changes in the constitution of the individual molecules themselves are mainly outside the province of physics, which is competent to reason only about permanent material systems; they must be left to the sciences of chemistry and physiology. Yet the chemist proclaims that he can determine only the results of his reactions and the physical conditions under which they occur; the character of the bonds which hold atoms in their chemical combinations is at present unknown, although a large domain of very precise knowledge relating, in some diagrammatic manner, to the topography of the more complex molecules has been attained. The vast structure which chemical science has in this way raised on the narrow foundation of the atomic theory is, perhaps, the most wonderful existing illustration both of the rationality of natural processes and of the analytical powers of the human mind. In a word, the complication of the material world is referable to the vast range of structure and of states of aggregation in the material atoms; while the possibility of a science of physics is largely due to the simplicity of constitution of the universal medium through which the individual atoms interact on each other.

The reference of the uniformity in the interactions at a distance between material bodies to the part played by the æther is a step towards the elimination of extraneous and random hypotheses about laws of attraction between atoms. It also places that medium on a different basis from matter, in that its mode of activity is simple and regular, whereas intimate material interactions must be of illimitable complexity. This gives strong ground for the view that we should not be tempted towards explaining the simple group of relations which have been found to define the activity of the æther by treating them as mechanical consequences of concealed structure in that medium; we should rather rest satisfied with having attained to their exact dynamical correlation, just as geometry explores or correlates, without explaining, the descriptive and metric properties of space. On the other hand, a view is upheld which considers the pressures and thrusts of the engineer, and the strains and stresses in the material structures by which he transmits them from one place to another, to be the archetype of the processes by which all mechanical effect is transmitted in nature. This doctrine implies an expectation that we may ultimately discover something analogous to structure in the celestial spaces, by means of which the transmission of physical effect will be brought into line with the transmission of mechanical effect by material framework.

At a time when the only definitely ascertained function of the ether was the undulatory propagation of radiant energy across space, Lord Kelvin pointed out that, by reason of the very great velocity of propagation, the density of the radiant energy in the medium at any place must be extremely small in comparison with the amount of energy that is transmitted in a second of time. This easily led him to the very striking conclusion that, on the hypothesis that the æther is like material elastic media, it is not necessary to assume its density to be more than 10^{-18} of that of water, or its optical rigidity to be more than $10\ 10^{-8}$ of that of steel or glass. Thus far the æther would be merely an impalpable material atmosphere for the transference of energy by radiation, at extremely small densities, but with very great speed, while ordinary matter would be the seat of practically all this energy. But this way of explaining the absence of sensible influence of the æther on the phenomena of material dynamics lost much of its basis as soon as it was recognised that the same medium must be the receptacle of very high densities of energy in the electric fields around currents and magnets. (We can here only allude to Lord Kelvin's recent most interesting mechanical illustrations of a solid æther interacting with material molecules and with itself by attraction at a distance: unlike the generalised dynamical methods expounded in the text, which can leave the intimate structure of the material molecule outside the problem, a definite working constitution is there assigned to the molecular nucleus. It is pointed out in a continuation that is to appear in the *Phil. Mag.* for September that a density of æther of the order of only 10^{-9}, which would not appreciably affect the inertia of matter, would involve rigidity comparable with that of steel, and thus permit transmission of magnetic forces by stress. This solid æther is, however, as usual, taken to be freely permeable to the molecules of matter.) The other mode of explanation is to consider the æther to be of the very essence of all physical actions, and to correlate the absence of obvious mechanical evidence of its intervention with its regularity and universality.

On this plan of making the æther the essential factor in the transformation of energy as well as its transmission across spaces, the material atom must be some kind of permanent nucleus that retains around itself an æthereal field of physical influence, such as, for example, a field of strain. We can recognise the atom only through its interactions with other atoms that are so far away from it as to be practically independent systems; thus our direct knowledge of the atom will be confined to this field of force which belongs to it. Just as the exploration of the distant field of magnetic influence of a steel magnet, itself concealed from view, cannot tell us anything about the magnet except the amount and direction of its moment, so a practically complete knowledge of the field of physical influence of an atom might be expressible in terms of the numerical values of a limited number of physical moments associated with it without any revelation as to its essential structure or constitution being involved. This will at any rate be the case for ultimate atoms if, as is most likely, the distances at which they are kept apart are large compared with the diameters of the atomic nuclei; it, in fact, forms our only chance for penetrating to definite dynamical views of molecular structure. So long as we cannot isolate a single molecule, but must deal observationally with an innumerable distribution of them, even this kind of knowledge will be largely confined to average values. But the last half century has witnessed the successful application of a new instrument of research, which has removed in various directions the limitations that had previously been placed on the knowledge to which it was possible for human effort to look forward. The spectroscope has created a new astronomy by revealing the constitutions and the unseen internal motions of the stars. Its power lies in the fact that it does take hold of the internal relations of the individual molecule of matter, and provide a very definite and detailed, though far from complete, analysis of the vibratory motions that are going on in it; these vibrations being in their normal state characteristic of its dynamical constitution, and in their deviations from the normal giving indications of the velocity of its movement and the physical state of its environment. Maxwell long ago laid emphasis on the fact that a physical atomic theory is not competent even to contemplate the vast mass of potentialities and correlations of the past and the future, that biological theory has to consider as latent in a single organic germ containing at most only a few million molecules. On our present view we can accept his position that the properties of such a body cannot be those of a "purely material system," provided, however, we restrict this phase to apply to physical properties as here defined. But an exhaustive discovery of the intimate nature of the atom is beyond the scope of physics; questions as to whether it must not necessarily involve in itself some image of the complexity of the organic structures of which it can form a correlated part must remain a subject of speculation outside the domain of that science. It might be held that this conception of discrete atoms and continuous æther really stands, like those of space and time, in intimate relation with our modes of mental apprehension, into which any consistent picture of the external world must of necessity be fitted. In any case it would involve abandonment of all the successful traditions of our subject if we ceased to hold that our analysis can be formulated in a consistent and complete manner, so far as it goes, without being necessarily an exhaustive account of phenomena that are beyond our range of experiment. Such phenomena may be more closely defined as those connected with the processes of intimate combination of the molecules: they include the activities of organic beings which all seem to depend on change of molecular structure.

(To be continued.)

Correction.—In the first part of the description of Sunderland's new electric tramways, which appeared in our issue of the 31st ult., the British Thomson-Houston Company were inadvertently mentioned as the contractors for the overhead equipment of the lines. Later on in the article, however, due credit was given to Messrs. Dick, Kerr, and Co. for the whole of this section of the work. It may be mentioned that Messrs. Dick, Kerr, and Co. also supplied the cars, which were built and fully equipped at Preston.

THE DESIGN OF RAILWAY CARRIAGES.

An inspection of the designs of railway carriages which have been built in recent years for our various steam railways, discloses the fact that the main object kept in view is to provide accommodation for as large a number of passengers as possible in a given space. In consequence of this dominant idea being carried too far in certain cases, the passengers using the railway carriages in question have to undergo each day a large amount of personal inconvenience. For instance, carriages are to be found on a number of our suburban lines in which the space between the seats is not sufficient, so that the knees of passengers upon the opposite sides are almost always in contact. As a result, the operation of leaving a full carriage is one which demands the skill and strength of an athlete. When these are wanting, it is even doubtful if a robust passenger will ever succeed in getting out unless others on one side of the carriage first step out on to the platform. The railway companies using these carriages, of course, succeed in carrying rather more people per given length of train than they otherwise would do; they also succeed in delaying at every station the departure of the train beyond the time at which it should leave. In fact, the whole travelling population on that line are delayed a few minutes each morning and evening in order to save a few feet in the length of the train. This objection is not to be found on our great main-line trains, where the comfort of the passenger is considered. But here, again, the question of ingress and egress is not always considered as it should be. If one takes, for instance, the corridor carriages which are attached to certain well-known express trains, to which entrance can only be obtained from the ends of the carriage when the platform is on one side: when such a carriage gets to its destination this corridor is immediately blocked by porters trying to fight their way in and by porters and passengers trying to get out with luggage. As, however, the extra time taken to get the people out is not large compared with the time spent in the train, it is not such a serious matter as in the case of a train service where the length of time taken on a journey is seriously affected by the time the trains are waiting at intermediate stations. The question arises as to what is the best type of vehicle for lines such as the underground and the new electric railways which are being constructed in various parts of London. In looking into the question, it would be well to study the difference in the carriages on the Central London Railway and on the Metropolitan District Railway. This latter line has adopted throughout the old transverse compartments, which, having one door on each side, give a large number of points at which the passengers can leave or enter the train. With the carriages used on the Central London Railway, the platforms between two long carriages are the only points at which access can be obtained to the same. On each of these platforms an attendant is stationed, which involves more travelling servants than are employed on the District line. The result gained, however, is much superior. There is a good space on the platform between the carriages

Digitized by Google

to hold the passengers as they come on; and again, the design of the carriages themselves obviates the objections referred to above, both in the compartment and in the corridor types of carriages. In the carriages in the Central London Railway seating accommodation at either end is arranged in two rows along the sides of the carriage, so as to leave ample space between for people entering and leaving. The result is that when the train begins to slow up, those passengers who wish to get off naturally walk towards the end platform, and there is ample space for them to stand at the end of the carriage in the broad passage between those longitudinal row of seats. We have not at present reliable figures as to actual time saved by this construction of carriages and by the provision of a few well-controlled points of egress, as compared with the many doors (which all have to be closed by the guard) of the old compartment system. The impression, however, gained from journeys on the two lines is that the Central London trains do not stay more than half the time in the stations that the Metropolitan District ones do. Of course, the same consideration holds with regard to the driving of tramcars, but, owing to the more limited speed, the conditions for safeguarding the passengers are not so rigid. Our conclusion as a whole is that while electric traction can do much, as shown last week, to improve the communication between each of the great towns and their suburbs, the electrical engineer in designing his line must not be bound to the designs of rolling-stock which have been used for years with steam railways.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTROMAGNETIC INDUCTION.

SIR,—In your correspondence column for last week there appears a letter under the above heading, concerning which I should be glad if you would permit me to say a few words. Your correspondent, Mr. Dunton, has in a most weak and uncalled-for attempt to show slipshod language in a certain text-book, fallen ignominiously himself into the very pit which he, in such a patronising way, would have others to carefully avoid. The paragraph to which he takes exception reads as follows: "When a conductor is mechanically moved in a field transversely to the lines of force traversing that field, a certain E.M.F. is determined which sets up a current in the wire if its two ends are connected." After quoting the above perfectly correct and properly worded statement, Mr. Dunton, in a roundabout manner, describes the case of a rectangular coil of wire having its plane parallel to a uniform magnetic field, and moving transversely across that field; and then, after asserting, what is most obviously true, that there will be no current generated in the coil under these conditions, he evidently thinks that he has proved his case.

The reason why there will be no current generated in the coil under the conditions referred to is, that in each of the two parallel wires of the rectangle which is cutting the lines of the uniform field, there is impressed an E.M.F. equal in amount and opposed to each other through the neutral sides of the rectangle. It is the equivalent, in fact, of putting two cells of equal E.M.F. in opposition to one another, and has nothing at all to do with the change in the number of lines passing through the coil, and of which, like the snakes in Ireland, there are none. The example in no way detracts from the statement quoted from Messrs. Slingo and Brooker's text-book, which no more implies or suggests that the wire connecting the ends of the conductor referred to should have an equal and opposite E.M.F. impressed on it than it implies that an opposing cell should be connected up in the circuit. Remembering that the so-called "lines of force" are simply graphical means of representing the direction or "grain" of the medium or state known as a magnetic field, it is evident that the E.M.F. impressed on a conductor, whether it be in the shape of a rectangle or not, is dependent on the density of that field and the rate at which the conductor cuts it at right angles to its direction. It is not only *slipshod*, but emphatically *wrong*, to say that "as long as the rectangle still faces north and south *there will be no E.M.F. whatever*, because there will be no change in the number of lines passing through it." An E.M.F. *is* impressed on the two vertical sides referred to, but being equal and opposite no current results. But suppose that one of the vertical sides was moving in a weaker field than the other, there would in this case still be no change in the number of lines passing through the coil, and yet a current depending upon the difference between the two impressed E.M.F.'s would result. Your correspondent has found a veritable "mare's nest."—Yours, etc.,

F. JOHNSTON.

Beechcroft, Holywood, co. Down, Sept. 2, 1900.

CORRECTION.

SIR,—In reference to the article, "Indian Electricity," in your issue of Aug. 31, p. 289, we should like to point out that, in conjunction with Messrs. Siemens, we are supplying three direct-coupled sets for the lighting at Simla. We think in this instance the insertion of Messrs. Willans's name is an error.—Yours, etc.,

JOHN BELLISS,
(For Belliss and Morcom, Limited).

THE BRADFORD MEETING OF THE BRITISH ASSOCIATION.

The meeting at Bradford of the British Association for the Advancement of Science was opened by the presidential address by Prof. Sir William Turner, M.B., D.C.L., LL.D., D.Sc., F.R.S., which was delivered on Wednesday evening last in the St. George's Hall before a most distinguished audience.

The PRESIDENT referred to the fact that it was 27 years since the British Association had met in Bradford. At the first meeting the town had not been raised to the dignity of a city. That meeting was a very successful one, and he hoped that the present one would be equally successful. At their last meeting in Bradford, a distinguished chemist, Prof. A. W. Williamson, had presided, while at the present meeting the association had elected him to the presidential chair, and his life work had been the study of biographical science. Sir William Turner proceeded to discuss the methods of studying such a subject. Thus Edward Gibbon had told us that diligence and accuracy are the only merits which an historical writer can ascribe to himself. While these were fundamental qualities necessary for historical research, they were even more necessary to scientific research. By the application of these qualities new facts were discovered and tabulated, and a wider and more intimate knowledge of the processes of nature was acquired. Besides diligence and accuracy, a well-balanced mind and the exercise of prolonged thought and reflection were needed to obtain the true significance of a series of connected facts and observations. The president referred to the qualifications of William Harvey for scientific research as a typical example. He proceeded to review the great improvements which had been made in this century in the means of observation, and compared the disadvantages under which experimenters laboured even in the year 1830. It was exceedingly difficult, for instance, for a biologist of the present day to realise the conditions under which his predecessors of only 50 years ago worked. The president then reviewed the cell theory, first introduced with respect to vegetable matter in

Digitized by Google

1831 by Robert Brown, and proceeded to discuss the structure of cells and their multiplication. The following portions of the address were devoted to the phenomena known as karyokinesis and to the consideration of cell plasm. This led Sir William Turner to the consideration of the functions of cells and of nerve cells, the consideration of which has occupied the attention of biologists greatly of recent years. In the concluding portions of the address the all-important subject of bacteria was discussed, the president concluding by some notes on the Darwinian theory. The address was concluded in the following words:

"We know not as regards time when the fiat went forth, 'Let there be life, and there was life.' All we can say is that it must have been in the far-distant past, at a period so remote from the present that the mind fails to grasp the duration of the interval. Prior to its genesis our earth consisted of barren rock and desolate ocean. When matter became endowed with life, with the capacity of self-maintenance and of resisting external disintegrating forces, the face of nature began to undergo a momentous change. Living organisms multiplied, the land became covered with vegetation, and multitudinous varieties of plants, from the humble fungus and moss to the stately palm and oak, beautified its surface, and fitted it to sustain higher kinds of living beings. Animal forms appeared, in the first instance simple in structure, to be followed by others more complex, until the mammalian type was produced. The ocean also became peopled with plant and animal organisms, from the microscopic diatom to the huge leviathan. Plants and animals acted and reacted on each other, on the atmosphere which surrounded them, and on the earth on which they dwelt, the surface of which became modified in character and aspect. At last man came into existence. His nerve energy, in addition to regulating the processes in his economy which he possesses in common with animals, was endowed with higher powers. When translated into psychical activity it has enabled him throughout the ages to progress from the condition of a rude savage to an advanced stage of civilisation; to produce works in literature, art, and the moral sciences which have exerted, and must continue to exert, a lasting influence on the development of his higher being; to make discoveries in physical science; to acquire a knowledge of the structure of the earth, of the ocean in its changing aspects, of the atmosphere and the stellar universe, of the chemical composition and physical properties of matter in its various forms, and to analyse, comprehend, and subdue the forces of nature. By the application of these discoveries to his own purposes man has, to a large extent, overcome time and space; he has studded the ocean with steamships, girdled the earth with the electric wire, tunnelled the lofty Alps, spanned the Forth with a bridge of steel, invented machines and founded industries of all kinds for the promotion of his own material welfare, elaborated systems of government fitted for the management of great communities, formulated economic principles, obtained an insight into the laws of health, the causes of infective diseases, and the means of controlling and preventing them. When we reflect that many of the most important discoveries in abstract science and in its applications have been made during the present century, and, indeed, since the British Association held its first meeting in the ancient capital of your county 69 years ago, we may look forward with confidence to the future. Every advance in science provides a fresh platform from which a new start can be made. The human intellect is still in process of evolution. The power of application and of concentration of thought for the elucidation of scientific problems is by no means exhausted. In science is no hereditary aristocracy. The army of workers is recruited from all classes. The natural ambition of even the private in the ranks to maintain and increase the reputation of the branch of knowledge which he cultivates affords an ample guarantee that the march of science is ever onwards, and justifies us in proclaiming for the next century, as in the one fast ebbing to a close, that great is science, and it will prevail."

On Thursday the various sections were opened by presidential addresses. We commence elsewhere in this issue the text of the presidential address delivered by Dr. J. Larmor, M.A., F.R.S., before the Mathematical and Physical Section.

The president this year in the Mechanical Section is Sir Alexander R. Binnie, and we are compelled by the limited space at our disposal to give only an abstract of his address.

Sir ALEXANDER BINNIE commented on the fact that many of his distinguished predecessors in the chair had devoted their address to the general progress of engineering knowledge, or to some particular parts of the same. He proposed, therefore, to consider how and under what circumstances the advancement made during the present century, or even during the Queen's reign, became possible, as civil engineers were accustomed to define their position as being "the art of directing the great sources of power in nature for the use and convenience of man." Consequently their success or otherwise will depend on the estimate they may form of nature as a whole, and of those great sources of power which it places at their disposal. Undoubtedly in the history of the world there has never been a period when the study of nature has been so open and free from all prejudices of any kind whatever, as it has been during the past century; nor, perhaps, with but few exceptions, has there ever been in any age or country a time when nature and her laws have been investigated with so pure and steadfast an aim after actual truth, without the mind being prejudiced by authority or preconceived ideas derived from those great departments of human thought which deal more particularly with matters of faith, morals, and religion. Sir Alexander Binnie proceeded to show that this equanimity of mind in which one could now approach scientific subjects had hardly been possible in the past. The inductive method of study could not, however, be attributed solely to Bacon, as in the teachings of Socrates and Aristotle there were continual references to the importance of enquiry, observation, and induction. The president also referred to the work of Hipparchus and Ptolemy, and to the splendid work done by the Alexandrian philosophers. Numerous quotations were given from various old writers to illustrate the president's points, and the author then skipped a few centuries and started his *résumé* again from the revival of learning. To illustrate the progress which has been made since then, he exhibited a chart extending from the time of Edward IV. to the present year. This chart contains an enormous amount of useful statistics, and gives in a clear form data which indicates the progress of science and the arts, as well as all those social events which mark the increase of civilisation. Through Sir Alexander Binnie's description of the chart and of the progress of the various arts we do not propose to go in detail, but must quote his remarks on the progress of electrical science. He attributed to Davy, Faraday, and Tyndall the birth of our electro-chemical ideas of the present day, while the progress of electrical science was associated with names commencing with William Gilbert, in the sixteenth century, and extending down to the discoveries of Hertz of the present day. He pointed out that from the time of Volta, Ampère, and Oersted the rapid progress which electrical science has made has been due in no small measure to the manner in which its experiments have been treated, on strictly mathematical lines, by the master minds of such men as Maxwell and Kelvin, until at last we arrive at the demonstration, long foretold, of the wave theory, which renders wireless telegraphy an accomplished fact. Light to the engineer has at all times been of supreme importance, and as we scan the names on the chart from Galileo, Descartes, Huyghens, Gregory, Newton, up to Roemer's discovery of its velocity, through Halley, Herschel, and the illustrious Thomas Young, who perfected the undulatory theory, until at last we eventually come to those mysterious Fraunhofer lines, noticed also by Wollaston, and which were interpreted by Bunsen and Kirchhoff in 1860, since which period they have been applied as an aid to chemistry in the analyses of terrestrial and celestial bodies. In the theory of heat we have the experiments of Cavendish and Priestley investigated by Count Rumford, illustrated by Tyndall, and bearing fruit in Joule's mechanical equivalent. Perhaps none of the allied sciences appears so distant from our own profession as that of physiology.

Digitized by Google

The address was concluded in the following words, in which the author answered the question with which his address began: "Modern scientific thought is due to an enquiry into nature and her works, irrespective of all preconceived theories, and the breaking away from the authority which other departments of human thought and faith have in former ages imposed upon some of the earlier enquirers into science. Faith in religion has been defined as 'the substance of things hoped for, the evidence of things not seen,' which is quite apart altogether from the other and wider faith with which the scientific enquirer contemplates that vast, that stupendous, that beautiful universe which has been revealed to him by the teaching of his predecessors, and which inspires him with those hopes to which I have just alluded. On the teaching of the ancients Bacon remarks: 'The opinion which men entertain of antiquity is a very idle thing, and almost incongruous to the world; for the old age and length of days of the world should in reality be accounted antiquity, and ought to be attributed to our own times, not to the youth of the world which is enjoyed among the ancients, for that age, though with respect to us it be ancient and greater, yet with regard to the world it was new and less.' This idea is perhaps more and more beautifully expressed by Tennyson in the words, 'I, the heir of all the ages in the foremost files of time.' And in another respect, taking Bacon's teaching which he so often reiterates, as being a search after fruits, we must not imagine that the fruits of which he speaks are necessarily to be gathered in by the worker himself, for the pursuit of true science is often hindered by the too greedy effort to grasp the sordid rewards of the present, and, alas! Bacon himself will ever stand as a most painful example of the depth of degradation to which even the highest minds may fall. We must learn from nature what she is continually teaching, that her efforts are directed not solely for the benefit of the individual, but for the welfare and the advancement of the race. The fruits and the rewards which grow from a study of nature, and a truly scientific effort to expound her laws, are of a higher and a wider scope. And in contemplating the work of the great men of the past with whose names we have been so freely dealing, looking at the present attitude of the scientific mind, and our share in the application and directing of those great sources of power in nature, we may say:

"No more a wind-borne leaf upon the waves
Of time and chance, but one to whom is given,
To help the mighty purpose of the world,
To straighten crooked paths, to smooth the hills
Of sin and sorrow, that on some bright day
The great wheels of the world may run their course
Without one jar or check."

The following is the programme, as far as can be ascertained, in Section A, which section deals with mathematical and physical science:

THURSDAY, SEPT. 6.

On this day (yesterday) the president (Prof. J. Larmor, M.A., F.R.S.) read his presidential address at 10 a.m. The following papers were then read and discussed:

"Notes on M. Cremien's Experiment," by Prof. G. F. Fitzgerald, F.R.S.

"The Creeping of Liquids and on the Surface Tension of Mixtures," by Dr. F. T. Trouton, F.R.S.

"The Method of Investigating Correspondences between Spectra," by Mr. H. Ramage.

"The Report of the Committee on Radiation in a Magnetic Field," by Prof. G. F. Fitzgerald.

"An Experiment on Simultaneous Contrast," by G. J. Burch, F.R.S.

"A Quartz Calcite Symmetrical Doublet," by J. W. Gifford.

While the papers for to-day and the following day of the meeting are not quite settled for Section A, the list below gives a number that are accepted:

"The Fixation of Molecular Energy, and the Relation of Radiation to Temperature under their Thermodynamic Aspect," by Dr. J. Larmor, F.R.S; "The Apparent Emission of Cathode Rays from an Electrode at Zero Potential," by Mr. C. E. S. Phillips; "The Similarity of and the Effect of Electrical Stimulus on Inorganic and Living Substances," by Prof. J. C. Bose; "The Production of an Artificial Light of the same Character as Daylight," by Messrs. A. Dufton and W. M. Gardner; "Note on an Improved Standard Resistance Coil," by Mr. R. S. Whipple; "A Form of Wheatstone Bridge," by Mr. E. H. Griffiths, F.R.S.; "The Telautograph," by Sir William Preece, F.R.S.; "Note on the Propagation of Electric Waves along Parallel Wires," by Prof. W. B. Morton; "The Rainfall of the Northern Counties of England," by Mr. John Hopkinson; "The Weather of the North Atlantic Ocean in the Winter of 1898-9," by Captain Campbell Hepworth; "Report on Seismological Observations"; "Determination of Successive High Primes," by Lieut.-Colonel Allan Cunningham and H. J. Woodall; "On a Central-Differsnce Interpolation Formula," by Prof. J. D. Everett, F.R.S.; "On Newton's Contribution to Central-Difference Interpolation," by Prof. J. D. Everett, F.R.S.; "The Vector Potential of Electric Currents in a Field where Disturbances are Propagated with Finite Velocity," by Mr. S. H. Burbury, F.R.S.; "The Use of Multiple Space in Applied Mathematics," by Mr. H. S. Carslaw; "Report on Electrolysis and Electro-Chemistry;" "Report on Electrical Standards"; "Municipal Trading," by A. Priestman; "Trade Fluctuations," by John B. C. Kershaw; "Recent Changes Affecting the Legal and Financial Position of Local Authorities in England," by F. W. Hirst, B.A.; and "Municipal Buildings for the Overcrowded," by Auberon Herbert.

The arrangement of subjects is to be as below:

FRIDAY, SEPT. 7.

At 10.30 a.m. the president of the astronomical department of the section will deliver his address, after which the section will divide into two departments. In the physical department mathematical papers will be read and discussed, while the astronomical department will have papers on astronomy before it.

SATURDAY, SEPT. 8.

On this day papers on electrical subjects will be taken.

MONDAY, SEPT. 10.

The section will again meet and divide up into two departments, one taking mathematical papers and the other papers on meterology.

TUESDAY, SEPT. 11.

The physical department will consider papers on ions, while the astronomical department will also meet.

WEDNESDAY, SEPT. 12.

Electrical papers will be taken.

MECHANICAL SECTION.

In Section G a programme of papers was prepared some months ago, which we have published before and reproduce again now. Thus yesterday the following papers were read: "Bradford Waterworks," by Mr. James Watson; and "The Disposal of House Refuse in Bradford," by Mr. John McTaggart.

To-day (Friday) the papers will be: "Resistance of Road Vehicles to Traction," by Prof. Hele Shaw, F.R.S.; "Recent Tramway Construction, with Special Reference to the Denerbe System," by Mr. W. H. H. Dawson; "The Coal and Iron Ore Fields of Shansi and Honan, and Railway Construction in China," by Mr. J. H. Glass; "The Use of Expanded Metal in Concrete," by Mr. A. T. Walmisley; and "Power Generation—Comparative Cost by the Steam-Engine, Water-Turbine, and Gas-Engine," by Mr. J. B. C. Kershaw.

On Saturday, Sept. 8, Prof. R. Beaumont is to read a paper on "The Application of Photography to Textile Designing."

On Monday, Sept. 10, the report of the Small Screw-Gauge Committee will be read by Mr. W. A. Price, and the following papers: "Measurement of the Tractive Force, Resistance, and Acceleration of Trains," by Mr. A. Mallock; "The Liverpool and Manchester Electric Railway," by Sir W. H. Preece, F.R.S.; "The Design and Location of Electric Generating Stations," by Mr. A. H. Gibbings; "A Maximum Demand Meter," by Mr. J. H. Barker; "An Account of a New Form of Self-Registering Rain-Gauge," by Mr. J. W. Binnie; and "The Automobile for Electric Street Traction," by Mr. J. G. W. Aldridge.

On Tuesday, Sept. 11, the papers will be: "A New

Digitized by Google

Form of Calorimeter for Measuring the Wetness of Steam," by Prof. J. Goodman; "The Internal Architecture of Steel," by Prof. Arnold; "Shop Buildings," by Mr. E. E. Clark; and "Steam Raising and Smokeless Combustion," by Mr. H. R. Armitage.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.

We have received the following communication from the Executive Committee of the International Association of Municipal Electricians, whose headquarters are in Pittsburg, Pa.:

The fifth annual meeting of the International Association of Municipal Electricians, to be held in Pittsburg, Sept. 25, 26, and 27, will be the most profitable and interesting assemblage that has occurred in the history of the association. Pittsburg, "the workshop of the world," as it has been justly called, has the leading electric manufacturing works in America, employing daily over 4,500 persons, and this of itself ensures the delegates and their friends a world of interest, to say nothing of the thousands of other works and industries of all kinds located there. The committee having in charge the work of arranging for the meeting are straining every effort to make the convention a success in every sense of the word. Mr. Morris W. Mead, the chairman of the Executive Committee, and who is superintendent of the Pittsburg Bureau of Electricity, is giving every attention in his power to pushing the work of arranging for the meeting. He is ably assisted by Mr. Elmer G. Loomis, chairman of the committee on arrangements, and other members of that committee. Mr. Loomis is superintendent of the Bureau of Electricity of Allegheny, Pa.

Mr. Mead attended a meeting of the committee on arrangements, held at Newell's Hotel on Aug. 24, at which he stated that at least 300 delegates, accompanied by their wives and daughters, will attend the convention. The committee arranged for the reception of the visiting delegates and their friends when they arrive in the city, and if the delegates will notify Mr. Mead or Mr. Loomis at what time and upon what trains they will reach the city, members of the committee will be at the depôts to meet them and escort them to their hotels. It was decided at the meeting to form a Ladies' Reception Committee, with Mrs. H. P. Ecker at the head. This committee will arrange for the reception and entertainment of the wives and daughters of the delegates, meet them at the depôt, escort them to their hotels, and provide for their comfort during their stay in the city. Mr. Mead informed the committee that he had arranged with the American Bell Telephone Company and the Pittsburg Central District and Printing Telegraph Company for the free use of those companies' telephones to the delegates and their friends during their sojourn in Pittsburg, and also with the Western Union and Postal Telegraph and Cable Companies for the free services of their wires during that time. He also stated that it is expected that the railroad companies would arrange to issue to the delegates and their friends a one and a third fare from all points on the certificate plan, and that arrangements have been made at leading hotels for the accommodation of all guests at reasonable rates. By way of entertainment on the evening of the first day of the convention (Sept. 25), a trolley ride on special cars of the Consolidated Traction Company, the United Traction Company, the Monongahela Traction Company, and the Pittsburg and Birmingham Street Railway Company has been arranged. The route laid out over the lines of these companies is many miles in length, and passes through the most beautiful, picturesque, and historic scenes in the States. The lines traverse lofty hills, shady glens, and mile after mile of costly and magnificent residences; shady glens skirt acres upon acres of the finest parks in the world, and along mills, factories, and workshops, the value of whose manufactured products aggregate nearly 400,000,000dol. annually. During this trip luncheon will be served at Kennywood Park, one of the most beautiful places for the purpose on the route laid out. In fact, everything possible to make this ride one of the most enjoyable events of the meeting has been planned and will be carried out to the letter. Another meeting of the committee was held the following week, at which arrangements were completed for a carriage ride on the afternoon of the 26th over the beautiful boulevards of the East End, and theatre parties in the evening. An excursion and banquet on the steamer "Mayflower" on the afternoon and evening of the 27th on the Ohio and Monongahela rivers have also been arranged.

Mr. Mead is daily receiving dozens of letters from superintendents of municipal electrical bureaus, city electricians, and others interested in electrical affairs from all over the United States, in which they state their intentions of attending the convention, and enquire as to matters pertaining to it. The Western Pennsylvania Exposition of Industrial Arts will open at the time of the meeting, and special arrangements will be made for the delegates to attend in a body.

ST. PANCRAS.

The Electricity and Public Lighting Committee's report and the annual report of the chairman of the St. Pancras Electric Lighting Committee were presented to the Vestry on Sept. 5, and from these we extract as follows:

The committee have accepted applications from various sources for current to the equivalent to 365 amperes at the Regent's Park, and to 223 amperes at the King's-road station. They also recommended an extension of mains in Stanhope-street. In connection with the extension at the Regent's Park station, it is necessary that facilities be acquired to enable the mains from the new switchboard being carried through into Stanhope-street—the most direct and economical route is through 41, Stanhope-street. The owner refusing to grant a wayleave, the committee recommended that his freehold interest be acquired for the sum of £1,100.

The committee unanimously passed the following resolutions: "That the best thanks be accorded to Dr. Walter Smith for his able and interesting report, and for the manner in which he has presided over the meetings of the committee. That the committee desire to record their appreciation of the services rendered by Mr. G. A. Hodgkinson, the deputy-chairman and chairman of the Gas Sub-Committee, and also by Mr. Thornton Rutter and Mr. Jonathan Edgar, as chairmen of the Stations and Mains and Audit Sub-Committees respectively. That the committee also desire to record their satisfaction of the manner in which the work of the department has been carried on by Mr. S. W. Baynes, the chief electrical engineer, and Mr. A. E. Pycraft, the chief clerk, and the officers of engineering and clerical staffs respectively."

Abstract of Chairman's Report.

Gentlemen,—I have the honour of presenting to you the tenth annual report dealing with the work of the electricity and public lighting department from May, 1899, to September, 1900, during which time great advance has been made in the undertaking, which has necessitated many important extensions being carried out; and owing to the difficulty in obtaining the new plant much anxiety was caused your committee and the staff during the past year. New consumers have been connected to the mains representing an extra demand for supply to 11,305 16-c.p. incandescent lamps, 106 arc lamps, 25 motors, equal to 89 h.p. The accounts for the year 1899 recently presented to you show the very satisfactory revenue of £44,880. 7s., an increase over the previous year of £6,624. 6s. 8l., notwithstanding the concessions made during the year under the indicator system, by which the large sum of £6,536. 16s. 6d. was allowed off accounts as rebates to consumers. As the net result of the year's trading, after paying instalments (£3,374. 6s. 4d.) of loans and interest (£7,321. 8s.), there remained a net profit of £6,841. 19s. 11d., and with the sum of £1,892. 9s. 7d. brought forward from 1898, a sum of £8,734. 9s. 6d. remained for disposal. The surplus of £8,734. 9s. 6d. has been distributed as follows:

Written off for depreciation on accumulators	£1,000	0	0
" " " meters and switches...	600	0	0
Contribution to lighting rate.....	2 000	0	0
To reserve fund.....	4,000	0	0
Carried forward to next year's account	1,134	9	6

During the past year extensive alterations and extensions have been carried out at the Regent's Park station, and are now nearing completion, the additional plant consisting of four 850-h.p. engines and dynamos, six 500-h.p. dry-back marine boilers, condensing plant, feed-water heaters, new switchboard for private lighting, and new switchboard for public lighting, for which tenders have been accepted to the amount of £44 692. In consequence of the necessity of retaining some of the small engines that have been replaced by the larger ones, it has been

(a) Contribution of £1,000 received from electricity department in aid of lighting rate. (b) Contribution of £2,000 ditto. (c) Price increased 1d. per 1,000 cubic feet. (d) Increase of 3d. per 1,000 cubic feet in June quarter; a notification has been received of a further increase of 4d. from July 1, 1900. (e) Charges for reinstating by works department first made. (f) Wages of lamplighters increased from 21s. 6d. to 24s. per week. (g) Inclusive of all capital charges, repairs, maintenance, and interest and instalments of loans. (h) Price reduced to 5d. per unit. (i) Price reduced to 4d. per unit from June. (j) Price reduced from July 1, 1900, to 3d. per unit. (k) Half-year ending June. *Note.*—One arc lamp displaces on an average 4·5 gas lamps, but the standard of light is about 11 times greater.

Digitized by Google

found necessary to lengthen the engine-house by removing the test-room and smiths' shop, which will allow space for two engines, and also ensure more thorough ventilation to the engine-house generally. The new chimney shaft, which has also been completed during the past year, has now been in use for some months, and is working very satisfactorily.

The following tables show the progress of the undertaking from its commencement:

Contribution to lighting rate in lieu of further reduction in price	3 000	0	0
Reserve fund	12,000	0	0
Carried forward to account for 1900	1,134	9	6
	£18,288	14	1

In consequence of the great demand on the King's-road station, and the fact of the whole of the plant being in use without even a single stand-by, the attention of your committee has been seriously occupied by considering as to how the station can be increased, and the chief electrical engineer was instructed to prepare plans showing proposed extensions, with the result that negotiations were commenced to try and acquire the houses facing Great College-street, but owing to the great number of interests to be acquired, and the large amount asked for same, it was thought advisable to first acquire the freehold. The Ecclesiastical Commissioners were approached, and after several conferences they agreed to accept £7,500 for the whole of their interests, which, on the recommendation of your committee, the Vestry agreed to purchase; but in consequence of the present Vestry being shortly dissolved, it was thought advisable that the further consideration of the extension should be postponed until after the new corporation comes into existence, the engineer having been instructed in the meantime to consider as to the action to be adopted.

The work of the department having greatly increased, it was found necessary to find extra accommodation for both the clerical staff and also the large staff now under the distributing engineer. This has been met by converting the upper part of the new gas shop into offices for the distributing engineer and staff, and a meter-testing room, which has enabled the two rooms that have been rented for the past two years at 106, Great College-street to be given up, but as the work advances it will be necessary to consider as to providing still further office accommodation, which can probably be done when the extensions to King's-road station are taken in hand. There has also been erected during the past year a new stores shed at the back of the Pratt-street offices.

Owing to your committee having decided during the last year or two to carry out most of the extensions of mains by our own workmen without the aid of contractors, the outdoor staff has considerably increased, but I cannot allow the opportunity pass without testifying as to the very satisfactory, economical, and expeditious manner in which the work has been done under the able superintendence of Mr. W. A. Brown, our distributing engineer.

A large trunk main has been laid between the two stations at a cost of £5,550. Sanction has also been given to lay additional feeders to supply the Clearing House and Somers Town district at an estimated cost of £3,000. During the past year and half, 152 additional arc lamps have been erected in 43 thoroughfares, and besides the foregoing there are 227 lamps in 23 other thoroughfares. The lighting of Prince of Wales-road, Malden-road, and Queen's-crescent by the enclosed type of arc lamp not being satisfactory, your committee called upon the contractors to replace them by the Brockie-Pell open-type arc lamp, since which no complaints have been received, and they appear to be burning satisfactorily. Nearly the whole of the arc lamps sanctioned having now been completed, your committee have ordered a list to be prepared as to which of the streets should be next taken in hand, which, in view of the large increase of the price of gas, your committee are of opinion should be proceeded with.

In consequence of the war in South Africa and other causes, great difficulty has been experienced during the past year in obtaining supplies of smokeless steam coal, and in consequence numerous complaints have been received of the smoke nuisance, which have also been intensified by the difficulty of obtaining efficient stokers. Tenders have been accepted for smokeless coal at an increased price of 50 to 75 per cent. on previous year's contracts.

In consequence of the war in South Africa, four workmen employed by the department, who were reservists, were called up for service to proceed to the front, and in accordance with the resolution of the Vestry the wives of the men are receiving half-pay.

During the past year the alterations of the boundaries of the parish have been considered by your committee in connection with the electric lighting area, and I have attended several conferences with other members of your committee at the Board of Trade offices, and the matter is still pending a settlement.

In December, 1898, your committee reported to the Vestry that applications had been received from intending consumers whose premises are situated at the border line of the parishes of St. Pancras and that of Islington—Brecknock-road and York-road. The Board of Trade stated, in reply to a communication sent them on the subject, that it is a case for arrangement between the two Vestries. Acting on this, a communication was sent to Islington Vestry inviting them to appoint a small committee to confer with your committee, with the object of promoting a reciprocal agreement. A conference was duly held, and your committee subsequently received a letter from the Vestry of Islington, stating that as St. Pancras has no power to lay mains outside its statutory area, the Vestry of Islington is not empowered to grant it permission to do so. These views your committee did not concur in, and considered the action of the Vestry of Islington vexatious, but considering the conditions nothing further could be done in the matter until after the new boundaries of the parish come into existence.

Owing to the great success of the electricity undertaking your committee considered the time had arrived to considerably reduce the price for supply, believing that the installation was undertaken not so much to make a large profit as to benefit the inhabitants of the parish generally, by giving them a fine, clear, and economical light, and the Vestry, on your committee's recommendation, agreed to the following reduction in prices from June last—viz.: (1) for supply to consumers not using the maximum demand indicator, from 6d. to 5d. per unit; (2) the price to consumers using the maximum demand indicator, from 6d. per unit for the first 1½ hours, all after at 3d. per unit, to 6d. per unit for the first hour, all after at 2d. per unit; (3) supply for motor power, heating, etc., from 3d. to 2d. per unit; (4) church and chapels, from 5d. to 4d. per unit; (5) hospitals, from 6d. to 4d. per unit, or by maximum demand rates; (6) public street-lighting and municipal buildings, from 4d. to 3d. per unit. As a result of the above great reductions the price of electricity is now cheaper than gas.

PRESENT PRICE CHARGED FOR SUPPLY BY METROPOLITAN COMPANIES AND LOCAL AUTHORITIES.

Companies.	Private lighting.	Power and heat.	Public lighting.
Metropolitan ...	6d.-4d.	4d.	—
Charing Cross ...	6d.-4d.	4d.-2d.	—
City of London	4½d.	2d.	—

ON THE EFFECTS OF STRAIN ON THE THERMO-ELECTRIC QUALITIES OF METALS.—PART II.*

BY MAGNUS MACLEAN, M.A., D SC.

(*Concluded from page 312.*)

§ 14. For the soft copper wire (Table IX. below) the readings were in the same direction for weights on and off up to a permanent elongation of 1 per cent. After a permanent elongation of 4 72 per cent. the current with weight on was 0·00103 mikroampere per degree from stretched to unstretched through the hot junction, while with the weight off the current was 0·00075 mikroampere per degree from unstretched to stretched through the hot junction. For iron wire the current was in the same direction for weights on and off up to a permanent elongation of 0·35 per cent.; but after a permanent elongation of 3·41 per cent. the current with weight on was 0·00461 mikroampere per degree from unstretched to stretched through the hot junction, and with weight off 0 0069 mikroampere per degree from stretched to unstretched through the hot junction.

* Paper read before the Royal Society.

§ 15. In "Mathematical and Physical Papers," vol. ii, p. 270, § 109, Kelvin says: "I have thus arrived at the remarkable conclusion that when a permanent elongation is left after the withdrawal of a longitudinal force which has been applied to an iron or copper wire, the residual thermo-electric effect is the reverse of the thermo-electric effect which is induced by the force, and which subsists as long as the force acts." It seems (§ 14) that for small longitudinal strain in copper or in iron the direction of the current through the hot junction is the same, whether the force which produced the permanent strain is on or off; (2) that as the permanent elongation is increased by increased longitudinal forces, a stage is reached which gives zero current when the forces are removed; and (3) that for greater longitudinal forces and permanent elongations the direction of the current is opposite with the pulling forces off and on. It seems, in fact, that the permanent elongation must exceed a definite limit to produce reverse thermo-electric effects with the longitudinal force on and removed. I hope to further investigate this point, and to report the results to the society.

§ 16. The galvanometer used for the investigation of

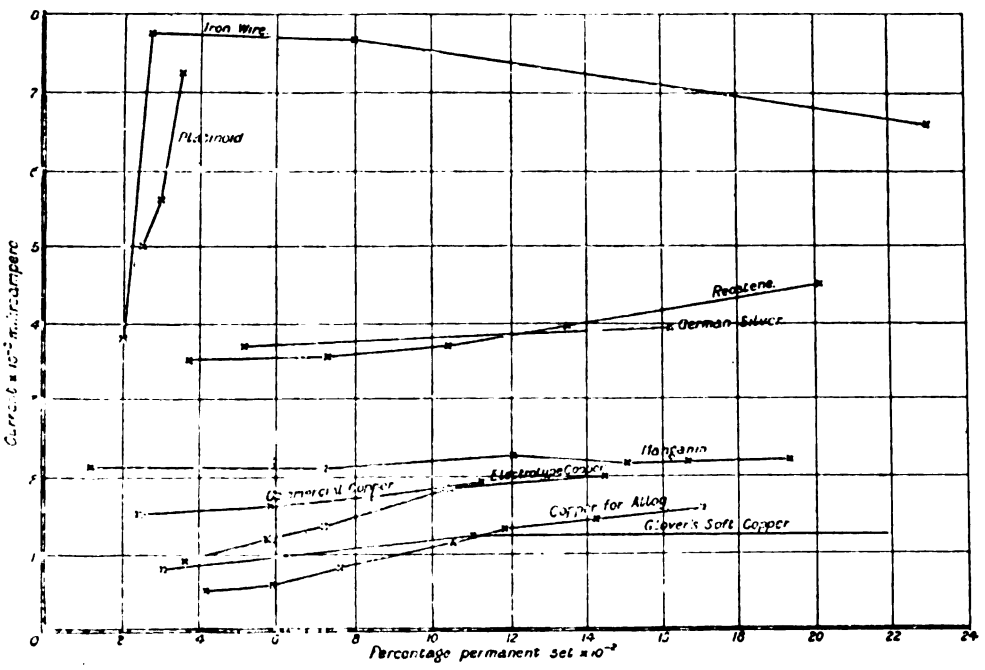
these temporary and permanent strains was one of the Kelvin recorder pattern—namely, a movable coil between the poles of a strong permanent magnet of circular form. The coil had 81 turns and a resistance of 14·94 ohms at 17·5deg. C. Its constant was determined in the usual way, and found to be 0·029 mikroampere per division of the scale.

§ 17. To find the stress-strain diagram, experiments were performed on a specimen of each wire in the following manner: Two pieces of the wire were passed through two small holes in a metal plate and soldered at the back of the plate. The plate was fixed to a horizontal support at a convenient height. One of the wires had a half-millimetre scale near its lower end, and a weight hanging on it to keep the wire straight. The other wire had a scale-pan and a pointer in the manner generally used in laboratories for finding the Young's modulus of materials. By putting weights into the scale-pan and taking them out, and noting the readings of the pointer on the scale, the temporary and permanent elongation in the wire for different weights were found. The numbers are given in the second and third columns of Tables V. to XIV. The currents in the fourth columns are calculated from the deflections of the galvanometer when the stated weights are on the wire, and the thermo-electric differences in the fifth column are found by multiplying the currents in the fourth column by the total resistance in the circuit in each case.

§ 18. The numbers in the tables are plotted in curves



with percentage permanent elongation as abscissæ, and thermo-electric differences as ordinates. The thermo-electric difference between free platinoid and strained platinoid rises rapidly with the permanent elongation of the strained wire. For manganin and lead, both commercial and pure, it is very nearly constant up to a permanent set of $\frac{1}{5}$ per cent. Mr. Alexander Wood, Thomson experimental scholar in the physical laboratory, the University, Glasgow, has rendered valuable help in the experimental work and in the calculations.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

305. Explain how to test the Aron new model watt-hour meters for alternating current at ordinary periodicity, if possible, with direct current.—A. S.

306. When running a dynamo and cells in parallel, if the voltage of both are the same, the current will be equally divided. Now, if the voltage of the cells drops one-eighth of a volt, will the whole of the current be supplied from the dynamo, presuming its capacity to be great enough and its regulating qualities perfect?—A. G.

ANSWERS.

Question No. 298.—I have a slow-revolution large-unit engine driving a dynamo. The speed of the dynamo is not uniform enough, and I wish to know where to look for and how to remedy this defect.

Best Answer to No. 298 (*awarded* 10*s.*).—The defect referred to in the question may arise from a number of individual causes or a combination of such causes, and to locate the actual one it is necessary to investigate separately all parts of the plant likely to detrimentally affect the speed of the dynamo. Commencing, therefore, at the dynamo itself, and assuming that it is indirectly driven by means of belts or ropes, it is evident that the ropes or belts may slip over the driven pulleys. If this occurs, and the slip is beyond the ordinary limits of practice, it may cause undue alteration of the speed of the dynamo, as the amount of the slip would be a variable and uncertain quantity. The slipping of the belts or ropes may arise either from them being too small for the power transmitted, or the pulleys may be wrongly proportioned, or the drive too short. Assuming, however, that there is no undue loss of speed from the drive, or that the dynamo is a directly-driven one, we limit the causes of the fluctuation of the speed to the engine proper. The load on the dynamo may be regular or irregular in character, and if the latter the investigation of the cause of the absence of uniformity of speed is rather more complex.

Considering first the simpler case, that of a regular dynamo load for a fairly lengthy interval, it is evident that the governor, which is the first important detail of the engine we should examine for variation of the speed, is not at fault for the following reasons: An early cut-off, consequent upon expansive working of the steam, combined with momentum of the moving parts of the engine, such as the piston, connecting rod, etc., result in the twisting effort of the shaft varying from a maximum to a minimum, and this tends to variation of the speed. To counteract this, energy is stored up in the flywheel when the twisting effort is in excess, and is given out again when

Digitized by Google

the twisting effort is below the average resisting effort. It is evident, then, with the dynamo load constant and variation of the speed, that the flywheel is not heavy enough. Further, the fluctuation of speed in this case will occur every stroke, and will be periodic in character. The only course open, therefore, to improve the running is to put in a heavier flywheel. As a temporary measure, the valves might be readjusted to cut off the steam later in the stroke, for this would give more uniform pressure on the piston and a better turning effort, though probably at the expense of the economy.

In the case of an irregular dynamo load, the fluctuation of speed may arise either from defective governing or too light a flywheel, or both these causes acting concurrently. The governor may not be sufficiently sensitive, or it may be too sensitive and not powerful enough. In the latter event there would be "hunting," and this would be readily detected. The usual method of overcoming hunting when it arises from hyper-sensitiveness is to attach a dash-pot to the governor. If the governor is not sensitive enough and does not respond readily to slight changes of speed, it will probably be found necessary to replace it by one more nearly isochronous. If the expansion gear or the throttle valve requires considerable force to move it, the governor may not be powerful enough, and this, again, would lead to irregular running. The only satisfactory way to obtain good governing under these conditions is to resort to the "relay" system. In this system the governor acts on some independent power, which in turn actuates the valve gear. Good governing, however, cannot be obtained unless there is sufficient flywheel weight, as the governor only has control over the engine during the admission of steam, and this is often for only a very short period of the stroke. Thus during the remainder of the stroke the controlling force is the flywheel. In fact, the panacea for all the evils of irregular running is a heavy flywheel. With rope driving the speed of the engine does not usually vary very much, and the reason for this is that the rope drum is by construction necessarily heavy, and there is, therefore, plenty of flywheel weight. Should there be any doubt as to whether or not the flywheel is heavy enough, indicator diagrams should be taken, and an actual twisting effort diagram, taking into consideration the momentum of the moving parts, constructed. The difference between the twisting effort and the average resistance at any position of the stroke can then be compared with the reserve of momentum of the flywheel.

In the above considerations we have not noticed the case in which the variation may arise from bad setting of the valves and irregular boiler pressure, because in these cases there is very little difficulty in locating the cause.—E. T. T.

Answer to No. 298 (*awarded* 5*s*.).—It is not stated whether the speed variation is periodic during each revolution, or irregular, from time to time. In the latter case the fault may be due to bad governors. First ascertain that they are clean and working freely. See if there is any slackness or loose part in the linkwork controlling the valves. If all is correct, run the engine light and adjust governors to normal speed, with stop valve full open. Then run engine on full load (artificial). The drop in speed should not exceed 3 per cent. If more, and if irreducible by different setting of the valves, the governors are no good for the speed required, and should be changed. Note whether any hunting goes on. This may occur if governing is by throttle, owing to the valve being brought into action too quickly. Adjust so that steam is admitted more freely. If Corliss gear is used, pay attention to the trip gear and dash-pots—the latter often need an adjustment if air or oil be used as a buffer.

It may be that the governors only act on the high-pressure cylinder. If this is so, and there is a fixed cut-off on the low-pressure side, a sudden change of load on the engine would vary the speed in spite of the governors. This is because the charge of steam admitted on one stroke to the high-pressure cylinder has to do work on the succeeding stroke in the low-pressure cylinder, and the power developed may be in excess of or insufficient for the power required at that instant. The remedy is to have a receiver between the high and low pressure cylinders, and a separate governor operating the admission of steam into the low-pressure cylinder.

A periodic variation in each revolution is due to unequal turning moment on the dynamo shaft. There have been cases when the cranks of the high and low pressure sides of a compound engine have been placed at 180deg. to each other instead of 90deg. The variation in turning moment is in this case very great. If possible, without too much expense, this should be altered, and an intermediate receiver put in between high and low pressure cylinders.

An insufficiently heavy flywheel may be responsible for irregular turning, particularly at light loads on an engine governing by variable cut-off. The remedy is obviously to increase the weight of the flywheel. In very bad cases it is worth while to have a spring coupling, similar in construction to Ayrton and Perry's transmission dynamometer, placed between the coupling flanges of the engine and dynamo, and a flywheel mounted on the dynamo shaft. The flywheel tends to secure even turning, while the expansion and contraction of the springs takes up the irregularities in the turning moment not overcome by the engine flywheel.—J. A. S.

Answer to No. 298 (*awarded* 5*s*.).—It would have been of considerable service towards a comprehensive reply to this question if some details of the irregularities of the speed of the dynamo had been given; for it is now open to doubt whether by "the speed of the dynamo is not uniform enough," is meant the fact that after any considerable alteration in load the speed either increases or decreases somewhat and then gradually returns to the normal, or it may be that at full load the speed is under the normal for half or light loads; the explanations of the two phenomena are probably widely divergent.

If the speed fluctuates with any alteration in the load, the fault must be sought in the engine, and it will doubtless be found that the governor is too sluggish in its action, or that the lead of the valve requires adjustment. I should, however, advise the first attention to be paid to the governor. As we are told the engine is a slow-revolution one, the dynamo is evidently not direct coupled, but the power is transmitted to it either by means of ropes or belts. Here, then, may be a source of the lack of uniformity, and the first thing to be done should be to place a tachometer on the engine and see whether its speed be constant or if it fluctuates with that of the dynamo. Many electrical engineers appear to have only a very elementary knowledge of the principles of mechanical engineering, and appear to think that as long as the ratios of pulleys are correct everything has been done that is necessary for good driving, and hence you will often find 1¼in. and 1½in. ropes round a pulley 18in. or even less in diameter, and astonishment expressed because the ropes soon wear out, or because a great amount of slip occurs. Some time ago I was called in to account for the great drop in voltage between full load and no load in a 15 kw. dynamo driven off a mill engine. There was no question of the engine speed not being constant, but I found that the dynamo speed fell 150 revolutions per minute at full load below the normal. Upon investigation I found the power was transmitted from the line shaft to the countershaft by means of an *8in. double belt* running over 32in. and 16in. pulleys, and was informed that formerly there had been a light belt, but as it was thought the slip occurred here, *to improve matters*, the light belt was replaced by a heavy one. Unfortunately, the available space on the line shaft was very limited, as it ran near a wall, and I was only able to get in a 48in. driving pulley and 24in. driven one, but this alteration, together with the substitution of the original light belt, improved the drive sufficiently to maintain an approximately constant voltage. Hence I should direct my first attention to the ropes or belts; if, however, the variation of the speed occurs proportionately in the engine, the fault must be sought there. It is possible that the governors are at fault, or the engine is too small for its work, the valves may be wrongly set, or, what is quite as likely, judging from past experience, the steam or exhaust pipes may be of too small a diameter to convey the steam. If, there-

Digitized by Google

fore, the want of uniformity occurs in the engine, and is not due to slip in the ropes, I should advise "T." to take indicator diagrams at light, half, and full loads, when he should readily discover the fault, or if he is unable to do so himself, and will publish the diagrams, doubtless many of your readers would be able and willing to assist him.—M.

Question No. 299.—When the load is suddenly taken off an engine in ordinary cases it will race away, but in the case of an engine and dynamo coupled a dead short pulls the engine up instantly. Please explain this fully.

Best Answer to No. 299 (*awarded* 10*s.*).—The pressure of steam in the cylinder of an engine acting upon the piston is, of course, the force which tends to produce motion. In a compound engine it is the sum of the effect in each cylinder. Averaged up for a single stroke, this force may be said to vary as the mean effective pressure in the two cylinders. To reduce this mean effective pressure is to reduce the effort which the engine is capable of making, and may be brought about in two ways: one, by reducing the initial pressure in the cylinder by throttling the steam; and the other, by cutting off the supply of steam earlier in the stroke, and thus allowing it to expand to a lower final pressure. In the reverse way, of course, the effort of the engine may be increased. Now, when an engine is employed to drive a dynamo on load, it is upon overcoming the resistance to motion that the armature displays with reference to the field magnets that the power of the engine is almost entirely spent, and this resistance, other things being constant, is proportional to the current passing through the armature. With a given mean effective pressure in the cylinders and a given current in the armature, a certain fixed speed of revolution results, but it is evident that if the load on the dynamo vary, the mean effective pressure remaining constant, an alteration must take place in this speed, which could not be tolerated in ordinary electrical practice. To obviate these variations, a governor is fixed upon the engine, which varies the mean effective pressure as the load changes; in the majority of cases, however, it is necessary for a change in speed to take place before the governor comes into play, and thus it is evident that a slight irregularity of running would result were it not for the fact that a second governor is employed, in the form of a flywheel, which, by reason of its inertia, acts as a damper upon these momentary irregularities if suitably designed for the purpose. A governor of a good type, and suited to its work, will hold the speed of the engines within certain narrow limits for all values of current from 0 to a considerable percentage of overload, but it will plainly be seen that there is a certain limit beyond which it cannot go. If it is a throttle governor, it cannot admit more than full-pressure steam into the high-pressure cylinder, and if the current is so great that this is insufficient to keep speed the engine will slow up. With a cut-off governor the maximum effect would be to allow the steam to enter the cylinder throughout the whole stroke (though, for various reasons, very few governors do this), and a similar slowing up will result if this is insufficient.

Now, referring to one half of the question: with a dead short on the armature circuit, an almost incredibly high current results, depending in amount upon the voltage, armature resistance and self-induction, duration of short, etc., and the resistance to motion on the part of the armature may be so increased not only to absorb, almost instantaneously, the energy stored up in the flywheel (which comes first into play as a regulator whilst the governor is acting), but to be far and away beyond the maximum effort that the engine can make however governed, and one can well imagine the engine pulling up.

With regard to the other half of the question—as to racing away when the load is suddenly removed—this would only occur to a slight extent if the governor were working properly and the flywheel suitably designed. Should it be only a momentary race, it means probably that a heavier flywheel is needed, or that the governor is acting sluggishly; but with a permanent race it means that the governor is not properly set, or else is incapable of closing sufficiently within the required limits of speed. The test for a reliable governor is to run the engine upon full load and then suddenly switch all load off, and note both momentary and permanent rise in speed.

It may be mentioned, by the way, that a cut-off governor, acting at extremely light loads, really acts as a throttle governor, because the cut-off takes place before the admission valve is fully opened, so that the cylinder does not have a chance to receive full main pressure.—W. G. M.

Answer to No. 299 (*awarded* 5*s.*).—There is a great difference in the question of an engine suddenly losing its load and a dead short on a direct-coupled set. Take the case of an engine losing its load suddenly: before the governor can cut off the extra steam which the engine has been taking, the engine is thrown into a state where steam is only required at part of stroke, using considerably less steam than before. This extra steam admitted to the engine causes it to rush forward, assisted by the inertia of the moving parts, until the governor again gets control. It is in this case where a shaft governor is preferred before a belt-driven governor, the former being quicker in its action on the cut off.

Now take the case of a dead short on the dynamo of a direct-coupled set. In a shunt machine the dynamo would lose its excitation, and after the first pause would give up generating current, and the engine would work on with no load. Suppose the dynamo to be compound wound, then it would try to burn out the short-circuit, with probably disastrous results to the armature, and as this would not take place before a large current, above the normal output of machine, is generated, the engine, which is designed with due regard to the output of the generator, would be taxed above its power and would slow down. The conductors on an armature regulate the output of the dynamo, and if the conductors are liberally designed, it is the engine which fails to take up the load.

The limitations of a direct set will be seen from the following: $C = \frac{E}{R}$. The volts, E, remain constant, but when a short occurs, the resistance, R, is reduced, thus increasing the current, C. Now $\frac{C \times E}{750}$ = horse-power. E has remained constant, but C is increased, so that the horse-power is more when a short is on the mains.

$$\text{Horse-power of any engine} = \frac{PLAN}{33{,}000}.$$

The length of stroke, L, and area of piston, A, and the pressure, P, cannot be altered at maximum load, so that N is the only factor which can increase; but the more current a dynamo generates, the greater the torque opposing the armature from revolving, and in this way the machine is pulled up. When the dynamo looses the load, this testing torque disappears and the engine races.—F. M. M.

Answer to No. 299 (*awarded* 5*s.*).—When the load is suddenly taken off, the engine races, because the governors are not sensitive enough, taking so many seconds or minutes, as the case may be, to reduce the amount of steam admitted into the cylinders, thereby keeping the speed constant when the load is reduced. It is a totally different case when a dead short occurs and the engine is pulled up. The resistance of the external circuit is reduced, and, therefore, following the well-known law of $C = \frac{E}{R'}$ there will be a larger current passing out of the generator causing the load on the engine to increase. The governors being slow to open the throttle valve, and when it is full open the engine not being large enough to take the increased amount of power needed, the result will be that the speed of the engine will decrease. If suitable fuses were put in the external circuit, the dead short would cause the fuses to blow, thereby decreasing the load on the engine.—C. G.

Question No. 300.—In designing a polyphase installation, what circumstances would guide you in selecting the number of phases and the frequency to be adopted?

Best Answer to No. 300 (*awarded* 10*s.*).—In designing a polyphase installation the first consideration would be which system is easiest to work combined with cheapness

Digitized by Google

Another consideration is whether the system is for a combined motor and lighting load, and it is safe to assume the load of the combined nature is meant in the question. The two-phase system is the simplest system to work motors and lights off the same mains. With three-phase working the uneven loading of the circuits is objectionable, and not only have the circuits to be balanced in the three branches, but the kind of load must be similar—it will not do to have an inductive load on one branch and non-inductive loads on the others. Another advantage in favour of two-phase working is the fact that two circuits of the two-phase system may be electrically disconnected, either always or during tests. This facilitates detection of troubles and gives greater security. Prof. Forbes prefers this two-phase system to the three-phase, especially where no earth return can be used. The three-phase system uses only three-quarters the copper in line wire, but this is counterbalanced by the complications used with this system. In conclusion, the merits as to which is the best system is open to argument, some favouring one system and some the other.

In selecting the frequency to be used when power only is required, a low frequency is adopted, but for lights a higher frequency is used, as a lower frequency would introduce complications into the lighting circuits too costly to justify this low frequency. On power circuits a high frequency means trouble with generators, motors, and the line. The frequency for lighting in England is from 80 to 100; power at Niagara, 25; power in Europe, 40 to 60. At 50 the fluttering of enclosed arcs is inappreciable at a few yards when arc is enclosed in an opalescent globe. A frequency of 60 will be found the best to adopt.—F. M. M.

Answer to No. 300 (*awarded* 5*s.*).—In selecting the number of phases in a polyphase installation, Prof. Forbes strongly advocates a two-phased system with the middle earthed, as having the advantage that the two circuits may be electrically disconnected either always or else during tests. If any consumer's plant uses only one-phase, two-phase or three-phase mesh must be used. Three-phase mesh subjects the transformers to 17 times the electric pressure experienced by three-phase star or two-phase, each earthed at the centre of the electric system. The chief circumstances for consideration are: Is the installation for transmission only, or for both transmission and distribution? Is the installation for purposes of light or power, or both? The same consideration should act as a guide in selecting frequency. The present tendency seems to point to a standard of 50 periods.—A. S.

COMPANIES' MEETINGS AND REPORTS.

CHLORIDE ELECTRICAL STORAGE SYNDICATE.

The annual general meeting of the shareholders of the Chloride Electrical Storage Syndicate, Limited, was held at the works and registered office, Clifton Junction, near Manchester, on Tuesday, the 28th ult., the chairman of the Company (Mr. F. H. Bowman) presiding.

The directors, in their report for the year ending June 30, 1900, stated that during the year the business of the Syndicate had continued to increase in a very satisfactory manner, the amount of orders received and goods manufactured being considerably greater than in any previous year. The capability of production at the works had been taxed to the utmost to meet the demand, and a large volume of orders had either gone by the Syndicate or been refused by it owing to its inability to execute them within a reasonable period. To meet the continually increasing demand considerable extension of the works and plant was becoming an imperative necessity, as also additional working capital. Negotiations had been entered upon for acquiring additional land adjoining the Syndicate's works. The balance-sheet showed that the profits for the year, after providing for debenture interest, amounted to £8,649. 15*s.* 5d., which the directors considered satisfactory, when the large increase in the cost of raw material and the conditions of production which have obtained during the year under review were taken into consideration. These, together with the execution of contracts arranged in 1897 and 1898 previous to the advance in prices, have seriously militated against the year's profit. After writing off from several accounts £4,391. 2*s.* 1d. (an amount which the directors thought necessary) there remained a balance of £4,258. 13*s.* 4d., to which was added £7,026. 10*s.* 5d. brought forward from last year, making £11,285. 3*s.* 9d. The directors proposed to carry forward the balance, out of which a dividend might be paid at their discretion. The retiring director under the articles of association was Mr. John Shepherd Baker, and the auditors Messrs. Parkinson, Mather, and Co.

The report and accounts were received and adopted, and the retiring director (Mr. J. S. Baker) and the auditors re-elected. Votes of thanks were passed to the chairman and directors and also to Mr. Grindle (the general manager), the secretary, and the staff.

MARCONI'S WIRELESS TELEGRAPH.

At a meeting of Marconi's Wireless Telegraph Company, held on Wednesday at the offices, Finch-lane, to enable the directors to announce an issue of 25,000 new shares of £3 each, a rosy picture of the progress of the new invention was presented by the chairman, Major Flood Page. A provisional agreement had been entered into with a firm of brokers, who would guarantee 12,500 of those shares at £3 each, and take at that price such of them as were not applied for, in consideration of a commission of 5*s.* per share on the 12,500 shares and their having a call at £3. 10*s.* up to March 31, 1901, on such of the remaining 12,500 as should not be taken up by the shareholders. That was a bona fide offer from a firm of considerable position, and showed the estimate they put on the value of those £1 shares.

Arrangements have been made with the Admiralty for the Company to fit 28 ships and four land stations with the new system. A naval officer has been experimenting, but could not get beyond what the chairman described as the "comparative failure" of speaking across 25 miles, while the Company is to provide instruments capable of communicating at 90 miles.

We take the above from the *Daily News*, to whose representative, it is stated, Signor Marconi confided that he regards 150 miles as already well within the range of his instruments, and is about to carry out experiments over 200 miles.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Lincoln.—The Town Council invite tenders for wattmeters and demand meters. Tenders by Sept. 14.

Hamburg.—Two 30-ton electric cranes are required. Enquiries may be made at the Town Hall. Tenders by Sept. 10.

Hampstead.—The Vestry invite tenders for various plant for their central station, Lithos-road, Finchley-road. Tenders by Sept. 27.

Piatra Neamtz (Roumania).—The Municipality invite tenders for the lighting of the town by electricity for 30 years by Nov. 2 (concession).

Plumstead.—The Vestry invite tenders for the supply and erection of various plant and machinery for electricity works. Tenders by Sept. 19.

Perth.—The Commissioners invite tenders for meters (direct-current) and cut-outs. Tenders by Sept. 15. Details in our advertisement columns.

Nottingham.—The City Council invites tenders for the construction and erection of a new power station at St. Ann's Well-road. Tenders by Sept. 21.

Philippopolis (Bulgaria).—The Town Council invite tenders for erection and working of electric lighting and working of tramways. Tenders by Nov. 4 (concession).

Oldham.—The Electric Light Committee invite tenders for the supply, delivery, and erection of boilers. Tenders by Sept. 11. Full details in our advertisement columns.

Nelson.—The Corporation invite tenders for the supply of a 200-kw. steam dynamo for their electricity works. Tenders by Sept. 8. Details in our advertisement columns.

Southampton.—The Harbour Board invite tenders from crane builders for one 30cwt. portable electric wharf crane. Tenders by Sept. 10. Details in our advertisement columns.

Hammersmith.—The Vestry invite tenders for two single-phase alternate-current motors, coupled to two centrifugal pumps, with accessories. Tenders by Sept. 12. Full details in our advertisement columns.

Horton (Surrey).—The Asylums Committee of the London County Council invite tenders for the installation of boilers, engines, dynamos, etc., at the Horton Estate, Epsom, Surrey. Tenders by Sept. 22.

Christiania (Norway).—Tenders are invited for 100 Morse apparatus, 100 Morse keys, 100 galvanometers, and 100 lightning conductors. Tenders to the Telegraph Department, Jernbane-torvet 8/9, by Sept. 12.

Hull.—The Electric Lighting Committee invite tenders for steam and water pipes, feed pump, water softener, etc., at their Sculcoates-lane generating station. Tenders by Sept. 27. Full details in our advertisement columns.

Southampton.—The Guardians invite tenders for the erection and completion of electrical plant and installation for the lighting of the new workhouse infirmary, Shirley Warren. Tenders by Sept. 11. Details in our advertisement columns.

Tunbridge Wells.—The Corporation invite tenders for the supply and delivery of high and low tension cables. Specification and full particulars can be obtained from Mr. Horace Boot, borough electrical engineer. Tenders by Sept. 20.

Digitized by Google

Preston.—The Guardians invite tenders for an electric light installation at Fulwood Workhouse, near Preston. Tenders by Sept. 10. Details in our advertisement columns.

Wrexham.—Tenders are invited for three electric motors and all accessories, working at 500 volts, to drive centrifugal pumps. Also one dynamo, capable of supplying energy for the above motors, together or singly. Details in our advertisement columns.

Greenock.—The Police Board invite tenders for traction plant as follows: water-tube boilers, two steam dynamos (high-speed enclosed engines), boosters, switchboard, steam and exhaust pipes, etc. Tenders by Sept. 10. Details in our advertisement columns.

Poplar.—The Managers of the Poplar and Stepney Sick Asylum District invite tenders from firms willing to perform sundry work in connection with the new telephonic installation at the sick asylum. Tenders by Sept. 10. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for the supply of two steel boilers for heating purposes, cast-iron pipes, etc.; rubber rings, bolts and nuts, steel stanchions, etc.; 100 car trucks. Tenders by 18th inst. Details in our advertisement columns.

Croydon.—The Town Council invite tenders for the construction of an underground electricity sub-station at Parchmore-road, Thornton Heath. Plans, etc., may be obtained at the Borough Electrical Engineer's Office, Factory-lane, Croydon. Tenders by 8th inst.

Hackney.—The Electric Lighting Committee invite tenders for condensing plant, cooling apparatus, pipework and valves, feed pumps, switchboard and boosters, public arc lamps, meters, travelling crane, and workshop equipment. Tenders by Sept. 12 Full particulars in our advertisement columns.

Walthamstow.—The Council invite tenders for the supply, delivery, and erection of electric lighting plant and apparatus, consisting of gas plant, gas engines, dynamos, switchboard, booster, balancer, and measuring instruments. Tenders by Sept. 25. Details in our advertisement columns.

Dundalk.—Tenders are invited by the Urban District Council for a transfer of their electric lighting order for the purpose of supplying electricity for public and private lighting and energy for manufacturing purposes within the urban district of Dundalk. Tenders by Sept. 18. Details in our advertisement columns.

Eastbourne.—The Corporation invite tenders for the supply and erection of a water-tube boiler, with fittings, feed pump, etc., a 400-kw. steam alternator, with exciter (vertical enclosed high-speed engine), and main switchboard and connections. Tenders by Oct. 4. Particulars appear in our advertisement columns.

London, E.C.—The Commissioners of H.M. Works and Public Buildings invite tenders for the enlargement of Block E of the telegraph factory at Mount Pleasant, E.C. Drawings, specification, and a copy of the conditions and form of contract may be seen on application to Mr. J. Wager, at H.M. Office of Works, etc. Tenders by Sept. 18.

Middleton and Castleton (Lancs.).—The British Electric Traction Company invite tenders for the construction of light railways in Middleton and Castleton, near Manchester (length in all about seven miles). Drawings may be seen at the offices of the Engineer to the Company, Lennox House, Norfolk-street, Strand. Tenders by 15th inst.

Salford.—Tenders are invited for the supply and delivery of the following materials for the ensuing 12 months: high and low tension single and concentric cables, and house fuse-boxes, meters, and meter boards. Full particulars from Mr. F. A. Wilkinson, borough electrical engineer (pro tem.), Electricity Works, Walmesley-road, Salford. Tenders by Sept. 10.

London, S.W.—The London County Council invite tenders for the supply within 12 weeks of the order being given of the mains required in connection with the electric light installation for the Victoria embankment and Westminster Bridge. Particulars may be obtained at the Engineer's Department, County Hall, Spring-gardens, S.W. Tenders by 24th inst.

Sunderland.—The Corporation invite tenders for the supply of (A) triple-expansion, high-speed, direct-current steam dynamos; (B) Lancashire boilers; (C) feed pumps. The several specifications and forms of tender can be obtained on application to the borough electrical engineer, Mr. J. F. C. Snell, A.M.I.C.E., Dunning-street, Sunderland. Tenders by 21st inst.

Aberdeen.—The Electric Lighting Committee invite tenders for supply of (1) two 200-kw. direct-coupled continuous-current generators and one 120-kw. balancing set; (2) one 420-kw. direct-coupled continuous-current generator. Specification and form of tender can be obtained from Mr. J. Alex. Bell, city electrical engineer, Cotton-street, Aberdeen. Tenders by Sept. 29.

Dublin.—The Electric Lighting Committee of the Corporation invite tenders for the supply and laying of electricity supply mains and accessories. Specifications and form of tender may be inspected at the office of the city engineer, Mr. Spencer Harty, M.I.C.E., City Hall, Dublin, and at the offices of Mr. R. Hammond, consulting engineer to the Corporation, 64, Victoria-street, S.W. Tenders by Oct. 4.

Mexborough.—The Council invite tenders for the supply and erection of a Lancashire boiler; two 50 kw. steam dynamos, balancer and boosters, feed-water heater, and feed pump; switchboard and connections; storage battery; mains; a five-ton hand travelling crane; and for adapting public street lamps from gas to incandescent electric. Tenders by Sept. 15. Details in our advertisement columns.

Blackpool.—The Tramway Committee invite tenders for the construction of a single and double line of tramways in Waterloo-road, Whitegate-drive, Raikes-road, Church-street, Abingdon-street, Talbot-road, and Central drive. The respective lengths will be about one mile single and 2½ miles double. The contract will include the laying of rails, points, etc., excavating, concreting, paving, etc. The Corporation will provide all the materials. Drawings may be seen and specifications and bills of quantities obtained on application to Mr. J. Wolstenholme, borough engineer, Town Hall, Blackpool. Tenders by 17th inst.

RESULTS OF TENDERS.

Salford.—The Electricity Committee have decided to recommend the acceptance of the tender of Messrs. W. T. Glover and Co., at £159 6s., for cables, etc.

Sydney.—The Railway Commissioners have placed with the Edward P. Allis Company a contract to furnish the engines for the Sydney tramways extensions.

Edinburgh.—The contract for an automatic coal-handling machine for the city electric light works has been placed with the New Conveyor Company, Smethwick, Birmingham.

Accrington.—The Corporation have accepted the tender of Messrs. Maund and Leed, 120, Lord-street, Southport, for the wiring of their electricity works, Argyle-street, at £215.

Aberdeen.—The following tenders are recommended for acceptance: A. Spark, Aberdeen, house main fuse-boxes; Ferranti, Limited, meters; British Insulated Wire Company, cables.

Blackpool.—The Hart Accumulator Company, Marshgate-lane, Stratford, have secured the contract for the supply of storage batteries required by the Corporation for the extension of their tramway system.

Rochdale.—The General Purposes Committee have accepted the tender of Mr. G. L. Adamson, 116, Yorkshire-street, for the wirings and fittings required in connection with the electric lighting of the town hall.

Melbourne.—W. T. Henley's Telegraph Works Company, Limited, have obtained an order from the Government for the supply of three miles of lead-covered, dry-core, paper-insulated, 26-pair telephone cable at £705.

Cardiff.—The Electric Committee have received, amongst others, the following tenders for steam pipes, heater, and pump for the works in Eldon-road: Messrs. Danks, £2 500; Messrs. Lace and Son, Cardiff £1,379*; British Insulated Wire Company, for street cable.* *Recommended for acceptance.

Bradford.—The Guardians have accepted the following tenders for lighting the workhouse: No. 1 section, C. A. Parsons and Co., £900; (3) Electrical Power Storage Company, £1,025; (4) G. A. Steinthal, £308; (5) G. F. Cook and Co., £613; for steam separator and steam trap, C. A. Parsons and Co., £20.

Leeds.—The Guardians have accepted the tender of Mr. Albert Dickinson, Upper Mill hill, Leeds, at £219. 10s., for the installation of electric light to the Poor-Law Offices, East-parade, Leeds. Messrs. Clayton, Sons and Co, Limited, Leeds, have secured a contract for four Lancashire steel boilers for the generating station at Crown Point.

Newcastle.—The Tramway Committee have accepted the following tenders: Mr. J. J. Robson, of Newcastle, for the new extension of the electric tramways in the west end of the city, for £26 505; Mr. Nuttall, of Manchester, for the east end of the city, for £26,072; and Messrs. Mather and Platt, extra pumping plant for the power station, £1,470.

Warrington.—The Museum, Library, Arts and Technical Instruction Committee have accepted the tenders of the National Electric Wiring Company for installation of electric light in the museum and library at a cost of £153. 4s. 1d., and of the Warrington and District Electric Light and Power Company for installation of electric light at the school of art at a cost of £53. 10s. 6d.

London, S.W.—The following tenders have been received for wiring the Town Hall, Walham Green, for the electric light, for the Vestry of Fulham:

C. Cooper and Co.	£493	10	0
Concentric and General Contract Company	637	0	0
National Electric Wiring Company	649	0	0
G. E. Taylor and Co.	671	10	0
F. Troy and Co.	695	0	0
T. L. Hellyar	725	4	0
D. Hulett and Co.	750	0	0
J. Bolding and Son, Limited	899	10	0
W. Douglas and Sons	1,249	6	0

Cleethorpes.—The Great Grimsby Tramways Company have received the following tenders in connection with the erection of electric power station, chimney shaft, car-sheds, workshops, etc., in Pelham road:

Power station.

Thompson and Sons	£7,967
Frere and Co.	7,800
Hewins and Goodhand	7,500
H. Marrow	6,522
Wilkinson and Houghton, Grimsby (accepted)	6,310

Depot.

Thompson and Sons	6 059
Frere and Co.	5 845
Hewins and Goodhand	5,440
H. Marrow	4,951
Wilkinson and Houghton (accepted)	5,003

Digitized by Google

Limerick.—The following are the lowest tenders received by the Borough Council in connection with the proposed electric installation for the city: plant, the Alliance Company, £12,157; lamps, the Schuckert Company, £335; cables, the Western Electric Company, £4 285. 4*. 8l.—total, £16,797. 10*. 8l. If the Corporation decided to accept one contractor for the whole work, Messrs. Porte and Sykes offer to do it at £17,000; Messrs. Porte and Sykes offer to supply Schuckert lamps and Glover's cables.

BUSINESS NOTES.

TRACTION.

Great Orme's Head.—A new mountain tramway to the summit of the Great Orme's Head has been sanctioned, and will be commenced almost immediately.

Leeds.—The Town Council on Wednesday decided to apply for parliamentary powers to construct several branch tramways as auxiliary lines to relieve the congestion in Boar lane.

Crewe.—The Council have endorsed the recommendation of the Electric Light Committee to go in for a scheme of electric tramways, to be worked in connection with the electric lighting station.

Halifax.—The Tramways Committee have received letters from the Queensbury and Shelf District Councils urging them to carry out the extension of tramways to their respective places "at the very earliest opportunity."

Bradford.—The new electric tramway along Thornton-road and Listerhills to Lidget Green has been inspected by Mr. A. P. Trotter, of the Board of Trade, and is now open for traffic. This adds another 1½ miles to the Corporation's system.

Wrexham.—The transfer of the property of the old Wrexham tramway company to the new company has taken place legally and effectively as from Aug. 8. The new company have taken over everything that belonged to the old company.

Aberdeen.—The Tramways Committee have been asked to report as to the advisability of applying for authority in the next session of Parliament to construct a tramway (double line) commencing at Market-street and terminating in Poynernook-road.

Nottingham.—We understand that it is confidently hoped by the officials responsible for the tramways now under construction that a start will be made some time during October, although great difficulty is being experienced in obtaining the necessary materials.

Hull.—William Long, a young man, pleaded guilty at Hull to embezzling 1d. while acting as a conductor on one of the electric trams of the city. He was sent to gaol for two months, with hard labour. On the same day six months was meted out to a clerk convicted of embezzling £6,000.

Army Motorcars.—Experiments will be made during the autumn manœuvres of the French army with a view of substituting mechanical for animal traction. By using motorcars it is expected that the transport will be much more rapid, while the forage problem will also be solved.

Newcastle.—As about 115 cars will be required to work the tramways, and 100 cars have been purchased already, the Tramways Committee on Tuesday agreed to purchase 35 more, so that there will be 20 additional cars for use during the midsummer holidays and on other special occasions.

Accidents.—Another alarming accident occurred in Paris last Sunday between an electric and a horse-drawn car. Three people were so seriously injured that they were removed to the Hospital Saint Louis. This makes the eighth tram or automobile accident during the past week, causing four deaths with injuries of more or less gravity.

Preston.—The Mayor, Aldermen Davies, Walmsley, and Pearson, Councillors T. Dewhurst, Copland, Margerison, Greenwood, Hamilton, Andrew, Hubberstey, and J. Foster have been appointed a special committee to consider the best way of giving effect to the powers as to tramways given by the Preston Corporation Act, 1900. They have been authorised to obtain the advice of such electrical or other engineer as they deem necessary.

Tramway Provisional Orders.—The Board of Trade has issued its report on proceedings under the Tramways Act. During the session of 1900 there were 36 applications for provisional orders under the Tramways Act—the largest number since 1881—and of these no fewer than 11 were from Lancashire. The aggregate length of the proposed lines was 59 miles of double line and 99 miles of single line, the estimated cost of construction amounting to £1,626,307.

Croydon Tramways Co.—At the ordinary half-yearly meeting of this Company, held on the 3rd inst. at Winchester House, Mr. T. K. Freeman presiding, it was resolved that, pursuant to the provisions of the Croydon Tramways and Improvements Act, 1900, the Company be wound up voluntarily. A resolution was also passed appointing Messrs. T. K. Freeman, W. Langley-Smith, W. P. Paige, and W. Feast as liquidators of the Company at a remuneration of £400.

Beddgelert Light Railway.—At a special meeting of the Portmadoc Urban District Council on Friday last Mr. Bennett, of Messrs. Bennett and Ward Thomas, consulting electrical engineers to a Manchester syndicate which intends applying for a light railway order for a line from Portmadoc to Beddgelert, attended in regard to the enquiry made whether the Council would entertain the question and, further, support the syndicate in applying for an electric light provisional order for the town. Replying to a member, Mr. Bennett said that at Pwllheli the syndicate had come to terms with the Corporation to supply public lighting at 4d. per unit and private lighting at 6d. per unit. The Council decided not to pass any resolution at present, but they are in favour of the project.

Letter-Boxes in Tramcars.—The *Bradford Observer* says: "In large towns which have adopted the tramways system the placing of letter-boxes in the cars confers a great boon to the inhabitants of the out-districts; yet the innovation, as inevitable as it is useful, is not taken kindly to by the Post Office authorities. Why this should be the case is not quite clear. At Halifax the Tramways Committee suggested it to the local postal authorities, but after a long delay the belated reply was that the privilege 'could not be recommended.' The municipality has offered to bear the cost of providing boxes, etc., so that there will be no expenses incurred by the Post Office. Now that the tramways extend several miles from the centre of the town, the inhabitants, say, of the remoter parts of Ovenden might easily have extended to them postal facilities greater than those hitherto enjoyed. Of course, collections need not be made at the end of every journey, except at nights, when the provincial dispatches could be met. The suggested innovation is bound to come."

Liverpool.—A new line serving the residential country district of Seaforth, Waterloo, Crosby, and Blundellsands was opened for traffic on Saturday. The new line is between two and three miles in length; it has been provided by the Liverpool Overhead Railway Company, and forms a continuation of their railway, which, extending from the Dingle to Seaforth, skirts the docks throughout its entire course of seven miles. The Tramways Committee recommend that Mr. P. M'Cullough, works superintendent and general assistant, at £360 per annum, be appointed assistant manager of the tramways at a salary of £500 per annum. The Tramways Committee were authorised on Monday to purchase from Messrs. Dick, Kerr, and Co. an additional 100 cars of a similar type to those at present being supplied under their existing contract, and at the price specified therein. Authority has also been given to the Tramways Committee to construct for electric traction certain lines mentioned in a report submitted from the city engineer and city electrical engineer to the committee on Aug. 5 at an estimated cost, including overhead electrical equipment, of £23 167.

Llanelly.—It has already been announced that the Llanelly Urban District Council has made arrangements with the British Insulated Wire Company to light the town with electricity and to provide electric traction. The *South Wales Daily News* states that an obstacle in the way of the project being speedily carried out has been removed. Mr. Solomon Andrews, of Cardiff, had an agreement with the Llanelly Tramways Company which entitled him to the use of the tramlines until next year, but negotiations have been carried on for some time with the view of inducing him to surrender the lease. Mr. Solomon Andrews visited Llanelly on Friday last and attended a meeting of the Llanelly Tramways Company at their offices in Stepney-street. As a result of the interview Mr. Andrews has agreed, on certain conditions, to give up his right over the lines on Sept. 29, and arrangements were also made by which his brother, Mr. James Andrews, of Llanelly, who works the tramcars, shall relinquish control of the cars, stables, etc., to the British Insulated Wire Company after that date. The road is now clear for the company to proceed with the project, as it is not anticipated that there will be any objection to their application to the Light Railway Commissioners, which will be heard in October next, to construct lines to the various villages around Llanelly.

North Durham.—The Bill for the construction of the Houghton and Sunderland line of tramways, which recently received the Royal assent, has received the sanction of the various Councils in the district—viz., the County Council of Durham, the Houghton-le-Spring and Hetton-le-Hole Urban District Councils, the Sunderland, Houghton-le-Spring, and Easington Rural District Councils, and the various parish councils. It is proposed to commence with the works during the current year. The overhead trolley system has been selected. Goods will be carried. The main line will start at Grangetown, Sunderland, and pass through Ryhope, Ryhope Colliery, Tunstall, New Silksworth, East Herrington, New Herrington, Philadelphia, Newbottle, Houghton-le-Spring, Hetton-le Hole, Easington Lane, on to Easington, and there will be branch lines from New Silksworth to Sunderland near Low Barnes, from New Herrington and Philadelphia to Penshaw Station, and from Houghton-le Spring to Fence Houses, a total length of about 20 miles. The engineers for the schemes are Messrs. D. Balfour and Son, civil engineers, and Messrs. Handcock and Dykes, electrical engineers, both of Newcastle-on-Tyne and London. Major Tulloch, C.B., R.E., late chief engineer of the Local Government Board, is chairman of the United Kingdom Tramways, Light Railway, and Electrical Syndicate, the promoters of the scheme.

Blackpool.—The *Gazette and News* has the following comment upon the breakdown in connection with the electrical tramway system last week: "The machinery at present in use is only calculated to generate the electricity required by 18 cars, but since the Claremont Park extension was opened it has been called upon to provide the motive power for 25 cars, and has therefore been greatly overloaded. New machinery to relieve this dangerous pressure has been on order for many months, but it has been found impossible to obtain delivery from the makers. The result was that on Tuesday night one of the 100-horse turbines broke down under the strain, and the tramway traffic on the promenade was altogether disorganised. Mr. R. C. Quin acted promptly in the

Digitized by Google

emergency, and as quickly as possible made arrangements with Mr. Cameron, manager of the Blackpool and Fleetwood Tramroad Company, for the necessary supply. The Fleetwood Company has fortunately some reserve plant which they were able to place at the disposal of the Corporation. It was arranged that the whole of the electricity required on the promenade line from the Gynn as far as the central pier should be supplied from the Fleetwood Company's works, while the other 100 h.p. turbine at the Corporation works would provide for the supply from the central pier southwards. In the meantime, Mr. Quin is hurrying forward the repairs to the broken-down turbine, and hopes to have it working again within a day or two. The electric lighting plant is also running at its top load just now. There was a greater demand for electricity on Saturday night than had ever previously been experienced at the local works, and every care is necessary on the part of Mr. Quin and his staff to keep the supply equal to the demand. In connection with this department, also, additional machinery has been on order for some time, but all the leading engineering firms are so congested with work that it is impossible to obtain delivery without long delay. However, there will be considerable extensions all round during the winter, and by another season arrives it is understood that both tramway and electric lighting departments will be fully prepared for all emergencies."

LIGHTING AND GENERAL.

Watford.—Mr. D. Smith has been appointed assistant electrical engineer.

Shrewsbury.—There is to be an extension of electrically lighting the public streets.

Dewsbury.—The voltage has been changed from 220 to 440 volts throughout the whole district.

Lurgan.—The Council are making enquiries as to the probable cost of lighting the town by electricity.

Crewe.—Another £10,000 will shortly be spent for the purpose of extending the public electric lighting.

Bradford.—Sanction has been obtained to a loan of £6,500 for the cost of electric lighting works at the workhouse.

Hawick.—An electric lighting company had secured a site in the town, and they expect to supply current before next July.

Birkenhead.—The expediency of reducing the charge for the use of electrical energy to 4d. per unit is under consideration.

Barnet.—The North Metropolitan Power Distribution Company started the electric lighting of the streets on Saturday last.

Stanley.—A special meeting will be held on Oct. 4 to consider the proposed application for a provisional order for electric lighting.

Halifax.—The Electricity Committee have decided to lay an electric main along Skircoat-road and Huddersfield-road at a cost of £1,900.

Wicklow.—The Urban District Council are taking steps to ascertain the feasibility and probable cost of supplying the town with electric light.

Wigan.—The work at the generating station and that of the tramways in general is progressing very rapidly, and the supply of current will be commenced shortly.

St. Pancras.—It is proposed that Messrs. S. Small and C. Williams be reappointed members of the Electricity and Public Lighting Committee of the Vestry.

Ripon.—The City Council intend to apply for an electric lighting provisional order, and Messrs. G. Harrison and Co., of Ure Bank, have been appointed consulting engineers.

Calverley.—The District Council have agreed to receive a representative of the North British Electricity Supply Company as to their proposal to supply the district with electric power.

Long Eaton.—The Urban District Council have decided to visit Northwich to inspect the Mond system of gas production, with a view to providing the power for their electric lighting scheme.

Warrington.—Mains are to be laid for lighting the infirmary with electric light. The price of electricity for motive power has been fixed at 2d. per unit for the first 3,000 units per quarter, and 1d. per unit after.

Alnwick.—The Urban District Council have decided to consent to the application of the Northern Counties Electricity Supply Association to ask for a provisional order for the lighting of the town by electricity.

Newark.—The Electric Light Committee are advertising for a site suitable for electric works. It is expected that £17,000 or £18,000 will be required for the scheme, and it will be necessary to provide for a loan.

Ilford.—Foundation stones were laid on Saturday of both the electric lighting station and the chimney shaft which are being erected by the Urban District Council for the purpose of generating electricity for lighting and tramways.

Grantham.—The Telephone Committee are of opinion that a municipal telephone system could be successfully worked, and have promised to lay a detailed estimate of the cost of the undertaking before the next meeting of the Town Council.

Kelso.—At a meeting of Burgh Commissioners on Monday communications were submitted from Messrs. Crompton, electrical engineers, and from the North British Electric Supply Company, who separately made proposals for lighting the town by electricity. The Board resolved not to take any steps at present in the matter.

Mexborough.—The electric engineer has been instructed to make provision for the lighting of the street lamps in the township, and to prepare the necessary plans, and to obtain tenders for the various works. Application is to be made to the Local Government Board for a loan.

Swansea.—The Electric Lighting Committee have decided to recommend Mr. James H. Cawthra, chief assistant engineer at Leeds electricity works, for the position of electrical engineer to take charge, under the superintendence of the consulting engineers, of the electric lighting works, at a salary of £300 a year. There were 75 applications for the post.

Eastbourne.—A resolution of the Highways and Drainage Committee recommending this committee to allow the erection of combined electric light and ventilating columns, in lieu of the existing columns in Wilmington-square and Lansdowne-terrace, for the purpose of ventilating the sewer on the Grand-parade is being considered by the electrical engineer.

Tredegar.—At the last meeting of the District Council the Clerk reported that several valuable concessions had been inserted in the South Wales Electrical Power Distribution Act, 1900, Clause 35 enabling the Council to exercise an absolute veto upon the company from obtaining any powers within the district for the supply of energy either for light or power.

St. Pancras.—At the St. Pancras Vestry's meeting on Wednesday, Dr. W. Smith, chairman of the Electricity Committee, in presenting the report, which we publish in another part of this issue, explained that the Vestry would hand over to its successors, the new borough council, a property worth £300,000, which had not, and would not, cost the ratepayers a penny. Had their undertaking been a joint-stock concern, it would have paid a dividend at the rate of 6 per cent.

London Gazette.—The last day for receiving proofs in the estate of B. Symmons (trading as B. Symmons and Co.), 2, North-street, Quadrant, Brighton, is Sept. 15. Mr. R. J. Ward, chartered accountant, 17, North-street, Brighton, is trustee.—An application for debtor's discharge *re* W. J. S. Green, 45, Birchfield-road, Aston, Warwick, will be made on Oct. 11, at 10.30, at the Court House, Corporation-street, Birmingham. — Messrs. Harrison and Brown, electrical engineers and contractors, Newcastle-on-Tyne, have dissolved partnership.

Appointments Vacant.—The Corporation of Eccles require the services of a consulting electrical engineer to advise them as to the extension of the existing electric light undertaking, including alterations required for the supply of power for tramway traction. The Town Council of Penzance having obtained an electric lighting order, propose to light the borough with electricity, and are desirous of receiving the names of electrical engineers who are prepared to advise them as to the best means of procedure. Particulars of these vacancies will be found in another column.

Tunbridge Wells.—At a meeting of the Town Council on Wednesday tenders were accepted for the installation of a municipal telephone service. The Corporation anticipate being able to provide a system which will cost subscribers £2. 10*s.* less than they are paying the National Telephone Company. The scheme also provides for a service to the surrounding villages. The town and district has been canvassed, and upwards of 300 subscribers obtained, and it is estimated that the initial cost of the installation will be £9,000 and the annual cost of maintenance about £1,000.

Stock Exchange. — The Stock Exchange Committee has appointed Sept. 13 as a special settling day for the Metropolitan Electric Supply Company's further issue of £125,000 3½ per cent. mortgage debenture stock, and has also ordered the same securities to be quoted in the official list. Applications have been made to the committee to appoint a special settling day in and to grant a quotation to Eastern Extension, Australasia, and China Telegraph Company's further issue of 50,000 shares of £10 each. The committee have further been asked to allow the Western Telegraph Company's 4 per cent. debenture stock to be quoted in the official list.

Price List.—We have received from Messrs. Ashmore, Benson, and Co., Limited, of Stockton-on-Tees, a list of their Invicta accumulators for electric ignition purposes. The cells are made in two and four volt series, there being three sizes in each series. The cells have capacities ranging from 12 to 40 ampere-hours, and the price in the four-volt series varies from £1. 5*s.* to £2. 10*s.*, and in the two volt series from 14*s.* 6*d.* to £1. 7*s.* 6*d.* The list is accompanied by testimonials from a number of users of the batteries, notably Mr. F. Chanon, who did so well in the Gordon-Bennett autocar race. The batteries have the advantage of being comparatively very light, and are small enough at the same time to enable an extra set to be carried even on motor tricycles.

Leith.—At Tuesday's monthly meeting of the Town Council the electrical engineer, Mr. J. Gray Scott, submitted an estimate showing that the cost of a new feeder to Newhaven-road would be £5,375. Interest and sinking fund would amount annually to £429, and the revenue would probably be £440 per annum. He also reported that on account of the increasing demand upon supply mains a new feeder to Bernard-street was absolutely necessary, at a cost of £1,217. He strongly recommended that the work be carried out without further delay. A report by the treasurer of police was also submitted, showing that the capital expenditure on the electric lighting undertaking to date was £43,011. 1*s.* 8*d.*, and that if extension of works were contemplated, it would be necessary to get further permission from the Secretary for Scotland to borrow. These matters were remitted to the Executive Sub-Committee for report.

Digitized by Google

Rotherham.—At the monthly meeting of the Town Council on Wednesday it was reported to the Gasworks Committee that the work of erection of the electric light generating station has been carried out expeditiously and in a satisfactory manner during the past month.

Chelmsford.—The Town Council have decided to increase the fines payable by the Chelmsford Electric Lighting Company for neglecting, or omitting, to provide the lighting to any of the public lamps. The fine for arc lamps is to be increased from 4*d.* to 6d. per lamp per hour, and for incandescent lamps from ½d. to 1d. per lamp per hour.

Heddeeden.—The Urban District Council will at their next meeting consider a letter from the Middlesex and Herts Electric Light and Power Company stating that they intend to make application by memorial to the Board of Trade for a provisional order to authorise the company to supply electricity for public and private purposes within the area of the Council.

"**English Illustrated Magazine**"—A gruesome but thoroughly characteristic Chinese yarn commences the September number, and various good short stories follow. The prize of merit for the number must be awarded to the very excellent reproductions of photographic views of river scenery. The two archæological and historical essays which follow are worth preserving.

Bath.—In consequence of applications received from Sion and Lansdown roads, the cable is to be extended at a cost of £370. The Council have also agreed to extend the low-tension cables to the top of Miles's-buildings, which would cost £45, and to the St. John's Roman Catholic Church, at a cost of £180. On account of the increased cost of fuel, the Council have decided to increase the cost ½d. per unit, both for public and private lighting.

Paris Exhibition Awards.—The British Schuckert Electric Company, Limited, was represented at the Paris Exhibition in the following four sections: Section 23, electrical machinery and motors; Section 25, electric lighting plant; Section 29, general plant; Section 118, electrical apparatus for marine and naval purposes, and has been awarded in all four cases the grand prix. The engineers and representatives of the firm have also received nine gold medals and eight silver and bronze medals.

Newbury.—The Board of Trade have issued a notice to the effect that the Newbury electric lighting order expired on Aug. 22. The order was obtained by the Corporation eight years ago, but was never taken advantage of in the sense of installing the electric light in the borough, no doubt owing to the fact that the gasworks belong to the town. Now that the order has expired, it will, of course, be open for any electric light company who may feel disposed to initiate the necessary steps for setting up electric light works in the town.

Bangor.—The new electric lighting works for Bangor are rapidly approaching completion, and it is expected will be opened some time this month. The demand for supply is still increasing beyond all anticipation. Over 1,000 lights more than it was calculated would be required in three years have already been connected. Two engines had originally been arranged for, one merely as a stand-by in case of accident to the other, but owing to the great demand for lights both engines will have to be kept working, and a third ordered the moment the works are started.

Gloucester.—Many suggestions have been received with regard to extending the system of arc lamps, which, it is stated, the committee will act upon at the right time. The resident engineer (Mr. Bache) has compiled the following figures giving the number of lights supplied: public street-lighting, 730; total number of lamps connected, 9,230; lamps now being wired, and for which application had been received, 1,960; lamps for which preliminary applications have been received, 2,134—total, 14,058. It is proposed that in future the cables should be laid under the channelling, instead of picking up the granolithic paving.

Bolton.—A canvass is being made as to the probable number of consumers for electricity in the event of the Tonge Moor-road cable being laid. The engineer's report as to the cost of laying the cable for furnishing a supply of electricity to Halliwell Mills has been referred to the chairman and vice-chairman. Further requests for the supply of electricity have been received, and the engineer has been requested to furnish estimates as to the cost of laying the requisite mains, and also ascertain the probable number of consumers therefrom. The question of hiring out electric motors has been referred to the General Purposes Committee for further consideration.

Seaham Harbour.—At the last monthly meeting of the Urban District Council a report of the Lighting Committee was adopted, stating that notice having been given by the gas company to determine the existing contract, the committee recommended that a deputation, consisting of Councillors Gibson, Berkeley, and Chilton, should negotiate with the company the terms of a new contract, if practicable, on the basis of a change for the whole of the Council's lighting. The clerk was recommended to get information of the cost of electric lighting at places approximate to the size of Seaham Harbour, Thirsk included, and also to ascertain the position of the Durham Electric Lighting Company.

Cheltenham.—The Electrical Engineer reported at the last meeting of the Council that all work, both of extension and ordinary running, had progressed satisfactorily during the past month. Since his last report more than a dozen customers had been added, with the equivalent of about 800 8-c.p. lamps, making the total number of 8-c.p. lamps connected equivalent to about 24,970. As he considered it was useless to wait longer in order to include all the works necessary for the traction scheme, he laid before the committee a detailed estimate of works to the value of £6,000, for sanction to borrow which sum he recommended that application should be made to the Local Government Board.

Catalogue.—We have received from the agents, Messrs. J. B. Guthrie and Son, on behalf of the Smith's Injector Company, Limited (late Smith and Co.), Station-street, Nottingham, an extremely well got-up catalogue descriptive of their various manufactures. In the preface the firm state that since the issue of their 1894 catalogue they have entirely remodelled their patterns, and introduced new and special machinery of the most up-to-date kind. The range of the list is a very wide one, and the illustrations are exceptionally good. They refer to various kinds of injectors, water-lifters, steam jet elevators, valves, gauges, standpipes, and general steam-boiler fittings. We specially note wheel-valves in gunmetal.

Catalogue.—We have received from Messrs. Brown, Boveri, and Co., of Baden, Switzerland, a copy of their latest illustrated pamphlet. The pamphlet, which is illustrated in an exceptionally good manner, contains a report on the more important installations carried out by Messrs. Brown, Boveri, and Co. during the last few years. The list of installations includes some in most of the European countries, and also two or three in the Transvaal. The work done by this firm was very favourably commented upon on the recent visit of our Institution of Electrical Engineers to Switzerland, and more particularly the work done by them in connection with the Burgdorf-Thun and Stanestad-Engelberg rack railways.

Belfast.—The last report of Mr. M'Cowen, the engineer, states that at the present time there were over 63,000 lamps in use in connection with the system, and that with the new extensions applied for the total number would be over 73,000. There was also a request for a considerable amount of power to work electric engines. An application has been received for a supply of electric light to 242, Shankill-road, and though this is a good distance from the electric mains in the neighbourhood, and it is estimated that it would cost close on £200 to make the connections, the Electrical Committee is willing, in view of the importance of the thoroughfare, to grant the application, provided they receive at least two other orders for current from the same neighbourhood.

Liverpool.—The increased demand for current for the tramways has led the Electric Power and Lighting Committee of the Corporation to make an important recommendation as to the staff of the city electrical engineer. It recommended the following promotions be made as from Sept. 1: Mr. A. Clough, works manager, with a present salary of £460, increasing to £500, to be assistant electrical engineer at a salary of £550, to be increased in 12 months to £600; Mr. R. S. Downe, assistant engineer, to be first assistant engineer at a salary of £320, increasing £40 per annum to £400 (present salary, £250, increasing to £300); Mr. C. H Smith, engineer's secretary, office superintendent, at a salary of £150 (present salary, £120); Mr. J. Stirrup, inspector of electric meters, superintendent meter department, at a salary of £130 (present salary, £110).

Enfield.—At the last meeting of the Urban District Council a letter was read from Mr. Shelton, as solicitor to the Tottenham District Council, who wrote: "Since meeting the House of Commons, I have made further enquiries with reference to the proposed application to Parliament for powers under the Electric Light Acts, and I am satisfied that it is most desirable that each authority should pass resolutions and take such other necessary steps as will put them in a position to apply to the Board of Trade for a provisional order. This is the only safe course to adopt, but should it be found, on proceeding with the proposed Bill conferring powers upon a joint committee of the several urban district councils, that the provisional orders are unnecessary, the steps for obtaining such orders can then be dropped." It was decided to consider the subject at a special meeting.

Tivoli.—In view of the ninth anniversary of the opening of the Tivoli Variety Theatre on Sept. 4, several alterations have been made in the building whereby additional exits and improved ventilation are obtained. The main feature is the execution of Mr. Seddon's scheme for the improvement of the ventilation of the lower part of the house. By the construction of an alcove in the grand circle saloon, a window opening direct into the open air has been gained. This is furnished with one of the General Electric Company's electric fans, which drives the vitiated air outside, while on the opposite side another similar fan, connected with an air shaft of a diameter of about 18in., and which is carried up as high as the roof, ensures a rapid supply of fresh air. These alterations have been carried out under the direction of Mr. Walter Emden. The contractors for the structural work were Messrs. Howard and Co.

Saltburn.—The handsome building adjoining the brine baths being erected by the Cleveland and South Durham Assets Company for the production of electricity, is now nearing completion. Cables have been laid underground, and the plant and machinery will shortly be ready to supply current for lighting and motive power. Several houses have already been wired by the owners at their own expense, and others are in progress. The National Electric Wiring Company have undertaken to instal, free of initial cost, complete installations for electric light at an additional charge of ½d. per unit on the current consumed. This charge will amount *in toto* to 6½d. per unit, and will represent on the average about 3 per cent. on the purchase price of the installation. Arrangements are being made by the wiring company to open a branch at Saltburn. We learn that an equivalent of over 3,000 8-c.p. lamps has already been installed.

Goole.—At a recent special meeting of the Urban District Council the question of electric lighting and the notification

Digitized by Google

which the Council had received that a syndicate intended to apply for a provisional order for Goole was discussed. A resolution was carried to the effect that steps be taken at once to obtain a provisional order, and that the clerk reply to the syndicate that they were already applying for a similar order and would strongly oppose the granting of an order to outsiders. Several councillors pointed out that the Council had recently spent and were spending large sums to get their roads in order, and it would never do to allow an outside company to come and cut up their roads. Moreover, the Council had special facilities of their own in the way of cheap gas, for providing electric power and light, and they were quite prepared to put a plant down and supply it to all who wanted it, and were not going to allow any competition with their lighting.

Devonport.—The report on the street-lighting, which was adopted by the Borough Council on Thursday in last week, includes the following paragraph: "In the undermentioned streets in Devonport electric light mains are about to be laid down for domestic supply, and we recommend that in those streets electric lighting be adopted, and suggest that both arc and incandescent electric lamps be installed, the arc lamps of high candle-power to burn from sunset to 12 o'clock midnight, and from midnight to sunrise a pair of 16-c.p. incandescent lamps to be switched on in substitution for the arc lamp. The annual cost of the electric lamps, including supply current, cleaning, trimming, carbons, renewals, and maintenance, would be about £19 per annum for each pillar. The streets we recommend should be lighted by electricity are: Fore-street 10 arc lamps, St. Aubyn-street 4, Tavistock-street 5, Marlborough-street 5, Newpassage-hill 4, William-street 4, Paradise-road 9—total 41. In each street incandescent lamps in the order previously given, as follows: 20, 8, 10, 10, 8, 8, 18—total, 82."

Haslingden.—On Thursday last week the electric light installation on the road leading from Irwell Vale to Ewood Bridge was formally started in the presence of the Mayor of Haslingden (Alderman Holt), Councillor Baxter (chairman of the Lighting Committee), Alderman Law, Alderman Barlow, Councillors Hoyle, Haworth, Lord, Whittaker, and Worsley, Alderman Schofield (of Rawtenstall, chairman of the Outfall Sewage Board), the town clerk (Mr. Walter Musgrave), the borough surveyor (Mr. Green), the lighting inspector (Mr. Harris), Mr. Tatham (manager of the sewage works), and Mr. Garland (representative of the contractors). The road is lighted with 13 32-c.p. Edison and Swan lamps, attached to wrought-iron brackets supported on wooden pillars. The power is obtained from a 100-volt dynamo in the engine-house of the sewage works, the cables being carried in two branches—one towards Irwell Vale and the other towards Ewood Bridge. The work has been carried out by Messrs. Garland and Co., of Accrington, to specifications prepared by the borough engineer, who has also superintended the operations.

The Sydenham Explosion.—The following report appeared in the *Daily Telegraph*: "At Sydenham, Mr. Howard Williams and Mr. Hallett concluded their enquiry on behalf of the Board of Trade into the boiler explosion at the works of the Crystal Palace Electric Supply Company, Limited, on July 25. Whilst a number of men were engaged in a building at the works the boiler burst, killing one man instantaneously, and causing such injuries to another that he died in hospital. The commissioners, in giving judgment, found that the explosion was due in the first place to the faulty construction of the boiler, in certain parts of which cast iron had been used. Messrs. Hornsby and Sons had explained that at the time—nine years ago—the boiler was constructed by them they had in their employ an engineer whom they had afterwards dismissed for passing faulty work; but, mainly, the fault of the explosion lay with the Crystal Palace Electric Supply Company. The company was ordered to pay £100 and costs, and the Engine Boiler Insurance Company £50 and costs. Messrs. Hornsby and Sons were not adjudged liable in costs, as the boiler had been made by them so long ago."

St. Paul's Lightning Conductors.—The system of lightning conductors on St. Paul's Cathedral has undergone a total rearrangement under the direction of Mr. Killingworth Hedges, M.I.E.E., and is now complete. The *City Press* says: "The electrician states that the old idea that the erection of a lightning rod on the highest point of a structure protected an area all round it is quite illusory. The safeguarded area was supposed to be the space within a circle whose radius was equal to the height of the lightning rod. This theory is now discredited, and the cathedral has been protected by a system of conductors, perpendicular and horizontal, comprising over a mile of cables, to which at various prominent points are placed about 50 'aigrettes'—groups of solid copper spikes radiating upwards, and effectually connected at the base with the cables. The old system of joint-making by 'junction pieces,' or splicing and soldering, has also been abandoned, it having been found that if surfaces were merely screwed together they were apt to oxidise and set up resistance, and if they were soldered the soldering sooner or later would be very likely to become loosened and detached by the natural expansion and contraction of the metals."

Carnarvon.—At a meeting of the Gwyrfai Rural District Council at Carnarvon on Saturday last a prolonged discussion took place on proposals made by Mr. E. W. J. Peterson, of London, to construct a light railway in the district and to supply the district with electric lighting. A joint committee representing the Council and the Carnarvon Town Council had suggested recommendations by which Mr. Peterson was to be authorised, at his own expense, to apply for the sole power of supplying electricity for lighting and other purposes within the area of the Gwyrfai Council, subject to the details being from time to time submitted to the District Council for its approval; and the same applied to the proposal for constructing a light railway from Carnarvon along the foreshore to Dinas Dinlle; while in the event of the promoters failing to obtain an order or, after obtaining an order, to carry out the work, they were to transfer to the two councils concerned the benefit of the electric lighting provisional order on the payment of a share of the costs incurred in obtaining the order. It was announced that the Parish Council of Llanrug had approved of the proposals, while that of Llanberis had adjourned coming to a decision. A long discussion took place, during which it was stated that if all these schemes were carried out an expenditure of about £100,000 would be required. Finally, the recommendations of the joint committee were adopted.

St. Albans.—The North Metropolitan Electric Power Supply Company by their Act of Parliament are authorised to establish a generating station for the supply of electricity at Ponder's End, where they have acquired a large site of land near the Edison and Swan Company's factories. They intend to transmit electricity at a high pressure over a large area. At each town and village through which the trunk mains pass, electric energy will be delivered for distribution at low tension for all purposes of light, power, and traction. The company assert that under this comprehensive system of supply, the public will obtain electricity on terms far more economical than by isolated systems put down for the supply of each town. The company are in communication with the Enfield Urban District Council, and are proposing to make arrangements with them, under which the necessary provisional order would be obtained, the supply organised at the expense and risk of the company, with power to the Council at the end of a short term to take over the undertaking (so far as Enfield is concerned) on terms of an ordinary valuation as a going concern. The area which the company proposes to cover reaches from Harpenden on the west to Waltham Cross on the east, and from Bedfordshire on the north to the confines of Hendon and Hornsey on the south. The scheme is not likely to clash with the St. Albans scheme, as under present conditions the North Metropolitan Company may go round St. Albans, but not within, so far as the electric lighting is concerned.

Aberdeen.—The electric lighting accounts, noted in our last issue, as well as the estimates for the current year, were adopted by the Town Council on Monday. We herewith give in full the remarks of the Chairman of the committee, from a report for which we are indebted to the *Aberdeen Journal*: "The demand for energy has more than doubled itself during the year just closed, a fact of no slight significance in view of all that has been said against it. In the absence of two complete years' accounts to compare with each other, observations on a few general points may be welcome. You will observe that we have borrowed £81,953, being an increase of £15,142 on the year. Of this amount we have redeemed, by means of the sinking fund, £5,185, leaving our net borrowing at £76,768. You will observe that a year ago the expenditure on lands, buildings, and plant, etc., stood at £69,713. 7s. 7d. From that there has been written off £2 438. 15s. 4d., while we have added during the year £26 091. 16s. — leaving the net total under this head at £93,366. 8s. 3d. Turning to revenue account, you find it given at £14,211. 3s. 10d., as against £4,804. 12s. 1d. for the seven months in last year's accounts. The gross expenditure is given at £6.062. 10s., as against £2,080. 18s. 11d. for the seven months last year. The balance carried to net revenue account this year is £8,149. 3s., as against £2,723. 13s. 2d. last time. The balance on net revenue account, after writing off interest on mortgages and other loans, as well as depreciation, is shown at £2,487. 18s. 11d., from which has to be deducted the small debit balance arising on the seven months' accounts last year, amounting to £203. 11s. 4d., leaving a surplus of £2,284. 7s. 7d. Account No. 8 furnishes a most interesting statistical comparison of energy generated and sold from the commencement of the undertaking. This year no fewer than 1,005,505 units were generated, as against 471,965 for the whole of 1898 and 279,953 for seven months of last year. This year the units taken by our public lamps have risen to 64,637 units. Tramway traction appears, of course, for the first time, with a demand of 131,173 units. Private consumers have called for 650,202 units, as against 232,172 for seven months last year. Turning now to the estimate for the current year, you will observe what the committee propose. We have, if the Irishism be permitted, 'lowered the price by not raising it.' Absurd although the phrase may appear, yet it exactly describes the operation. During the year that is passed we have paid heavily for coal, and we have been compelled to contract this year again at high prices, quite sufficient in themselves to justify us in raising our rates for energy, as Edinburgh did the other day, to the tune of ¼d. per Board of Trade unit all round. Instead of doing that, however, the committee felt it better to let what, in normal conditions, would have gone to reduce the rate be used up rather in meeting the enhanced cost of materials. It will, therefore, be seen that there is a real, although not nominal, reduction for the current year. We are on the strain now to meet the demands upon us for the coming winter, and, as the Council know, we are busily engaged considering plans for the best laying-out and equipment of our new station at Dee Village, which must be ready to meet the winter's load of next year to some extent. We hope to lay these proposals before you on an early date, so that not a day may be lost in having operations commenced." The prices for electric current for the next year were fixed by the Town Council at the same meeting as follows: For lighting—for the first hour daily of the maximum demand, 6d.; thereafter, 3d. per Board of Trade unit. For motive power—for the first hour daily of the maximum demand,

Digitized by Google

3d.; thereafter, 1d. per Board of Trade unit. These charges are the same as were imposed last year. The Kingseat (Newmachar) Asylum will be lighted by electricity, the machinery which will pump the water being utilised for the purpose of generating the current.

Sheffield.—The *Sheffield Daily Telegraph* has an account of an interview with Alderman Styring, the chairman of the Electric Light Committee, who made some interesting remarks on the present position of affairs, and also on Mr. Fedden's report. We quote as follows: "Mr. Fedden says: 'In Sheffield, very large provision must be made for the future, because not only are the suburbs extending rapidly (and these suburbs should be electrically lighted), but the central portion of the city, with its workshops and small power users, may be expected to make an unprecedented demand on the electric supply department as soon as you are able to supply electric energy suitable for power, heating, etc., at a reasonable charge, say 1½d. to 1d. per unit.' If he had to design a new system, he says, he should propose to distribute on the continuous-current system in the central area, although he would generate and transmit the electrical energy from one large power station by polyphase alternating currents to different points in the city, and there transform it into continuous currents by means of rotary converters. As, however, an expensive alternating system is already laid down, such a radical change is impracticable, and he confines himself to recommending modifications in the existing system, which will have the effect of bringing it up to date. One of his chief suggestions is directed to making the system more suitable for motive power, and he strongly recommends the reduction of the periodicities from 100 to 50. This lower periodicity is in operation in a number of towns, and, he says, 'another advantage of changing our present plant from 100 to 50 periods would be that the plant would then be suitable for running in parallel with the large power station which Sheffield must shortly possess. I may add that the quality of the lighting would not be prejudicially affected by the change.' 'If you sanction the suggested change,' the report proceeds, 'the sets of plant would have to be changed one by one as opportunity occurred, and, of course, during the change, each particular set would be unavailable for service on the load. To enable the alteration being carried out it will be necessary to order two sets of plant (alternating 50 period), say each of 1,000 kw., to be delivered, if possible, before March, 1901, and when these are installed to gradually transform the present sets set by set. The cost of altering the present system to 50 periods will be about £9,400 (this includes alternators, motors, meters, and arc lamps). To carry out the above recommendations I estimate the following further expenditure for 1901: additions and alterations in boiler-house, £3,500; 2,000 kw. of new plant complete, £22,000; additional feeders, £5,000; contingencies, say 5 per cent., £1,995—total, £41,895. If these suggestions are carried out, the present station will be completely filled up with machinery put on a footing to give the best possible results as a system. The building of a larger station should also be taken in hand without delay, so that it may be steadily proceeded with concurrently with the above recommendations. One of the questions which our representative put to the chairman of the Electric Light Committee was, 'Are the extensions contemplated in order to enable the department to supply more power or more light? Is there a great demand for power at present?' 'No,' replied Alderman Styring, 'the present demand for power is very little, but we expect it will increase very largely. The first claim is for light. We think the machinery we have got in the station will take us comfortably over this next busy season—at any rate, we hope to pull through, unless anything unforeseen occurs. But we should like to have more behind us than we have. Ever since the undertaking came into the possession of the Corporation, it has been perfectly clear that large developments would be necessary. The attention of the committee has been devoted first to keeping up the supply, and next to making provision for future requirements. The position of the matter is a good deal complicated by the fact that the subject of electric supply has apparently not yet assumed a final shape. We are also a good deal hampered by having taken over a system of supply already established, and to a considerable extent developed. If the field had been clear, the problem for solution would have been very much simpler and more easily tackled. Since Mr. Fedden assumed his duties, he has been actively engaged in mastering the details of the system as established in Sheffield, and considering the aspects of the case with a view to future developments, and his report, presented recently to the committee, is the outcome of those deliberations.' 'The new station will not be kept for power purposes solely,' was the answer to another question. 'It will have to be designed so that it will work in harmony with the present station, and supply both light and power. We should use the present station as a central one, and have the machinery coupled up with that in the new station, so that assistance could be rendered by the latter. It is too early yet to speak of any proposed site for the new station.' A further enquiry brought from the Chairman an answer emphasising the necessity of extensions. 'There is real need for more machinery for producing electric light,' he said. 'The demand is rapidly increasing, and keeps up with anything that the undertaking has experienced since its inception. The capacity of supply at present existing is only, at the best, equal—notwithstanding all that the committee have done—to the present demands, and the demands which will certainly be made during the next few months.' As has already been stated, Mr. Fedden's report has been referred by the committee to Mr. R. Hammond, the consulting electrical engineer to the Corporation, and the committee have decided to send a deputation to the Paris Exhibition, to examine the most up-to-date machinery on view there."

PROVISIONAL PATENTS, 1900.

AUGUST 27.

15225. Improvements in electric arc lamps. Hugo Bremer, 42, Neuenweg, Barmen, Germany. (Complete specification.)

15227. Improvements in or relating to machinery for the production of electrical energy. Herbert Samuel Elworthy, 322, High Holborn, London.

15246. Improvements in the manufacture of electrically-conducting bodies. Eberhard Sander, 18, Buckingham-street, Strand, London.

AUGUST 28.

15265. An improved joint-box for electric cables. George Alexander Clark, 34, Ann-street, Glasgow.

15285. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Alexander D. Lunt, United States.) (Complete specification.)

15298. Improvements in wireless telegraphy. Charles Edwin Wilson, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

15310. Cable-preserving channel for underground cables. Conrad Freysag, 11, Kronprinzenstrasse, Bonn-on-Rhine, Germany.) (Complete specification.)

15313. Improvements in automotor trolleys for electric current. Pierre Barthèlemy Louis Lombard-Gerin, 6, Lord-street, Liverpool. (Complete specification.)

15332. Improvements in apparatus for stopping, starting, and reversing electric motors. William Lloyd Wise, 46, Lincoln's-inn-fields, London. (The Skodawerke Actien-Gesellschaft, Austria.)

15334. Improvements relating to switches and apparatus for use in starting, controlling, and reversing electric motors. Arthur Henry Adams, 11, Southampton-buildings, Chancery-lane, London.

AUGUST 29.

15363. Improvements relating to the electro-deposition of metals upon articles of china, earthenware, and the like. George Cooke, Bank-buildings, George-street, Sheffield.

15378. Improvements in means for generating alternating electric currents. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Alexander D. Lunt, United States.) (Complete specification.)

15379. Improvements in regulating dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

15380. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz and William Le R. Emmet, United States.) (Complete specification.)

15381. Improvements in thermal electric cut-outs. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William Le Roy Emmet, United States.) (Complete specification.)

15382. Improvements in systems of electrical distribution. The British Thomson Houston Company, Limited, 83, Cannon-street, London. (Charles M. Green and John G. Callan, United States.) (Complete specification.)

15397. An improved railway signalling apparatus. Charles Edward Hobbs and Richard Deen, 55, Chancery-lane, London. (Complete specification.)

15398. Improved railway signalling apparatus. Charles Edward Hobbs and Richard Deen, 55, Chancery-lane, London. (Complete specification.)

15404. Improvements in incandescent electric lighting devices. William Phillips Thompson, 6, Lord-street, Liverpool. (The Voltohm Elektrizitäts Gesellschaft, A.G., Germany.)

15419. Improvements relating to the supply of current to electric vehicles by inductive means. Reginald Haddan, 18, Buckingham-street, Strand, London. (Ernst Sussmann Kellborn, Germany.)

AUGUST 30.

15457. Improvements relating to the production of electrical conducting bodies specially applicable for use in electric incandescent lamps. Eberhard Sander, 45, Southampton-buildings, Chancery-lane, London.

15470. Process of forming metallic electrode plates. Alfred Julius Boult, 111, Hatton-garden, London. (Ernst Andreas, Germany.)

15473. Process for the forming of electrodes. Alfred Julius Boult, 111, Hatton-garden, London. (Ernst Andreas, Germany.)

15475. Improvements in and in connection with the distribution of electrical supply. Frank Edward Beeton, 40, Chancery-lane, London.

Digitized by Google

AUGUST 31.

15479. Improvements in electric arc lights. Frank Edward Beeton, 3, Glen-villas, Folkestone-road, Dover.

15486. Improvements in or relating to overhead systems for the transmission of electrical energy. William Routledge, 73, St. Stephen's-road, Upton Park, London.

15483. Improvements in wireless telegraphy. Sidney George Brown, 9, Putney-hill, Putney, London.

SEPTEMBER 1.

15591. Improvements in automatic interruptors for electric circuits. Alfred Julius Boult, 111, Hatton-garden, London. (F. Katzenstein, Switzerland.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Sept. 22.

1899.

17445. Electric cables. Heyl-Dia.

17736. Electric telegraph apparatus. Brown.

18468. Electricity meters. Chamberlain and Hookham, Limited, and Holden.

18547. Continuous-current electric motors or generators of enclosed type. Wilson.

19103. Telephone conductors or cables. Joint-Stock Company, styled Kabelwerk Rheydt Aktiengesellschaft, and Zappe and Hohnholz.

19384. Electric clock systems. Lorrain. (Macdonald.)

19440. Electromagnetic wave apparatus. Armstrong and Orling.

20180. Indicating or recording and controlling the speed of electric railway cars or vehicles and other machinery. Nisbett.

20277. Electrical selector switch. Eckstein and Coates.

20321. Construction and arrangement of electrical resistance coils. Pye.

20655. Apparatus for use in forming joint ends on electrical conduits, drain pipes, and the like. Albion Clay Company, Limited, and Lawton.

20678. Electric switch. Houghton.

21076. Electric cells or batteries. Willcox. (Columbus Elektricitätsgesellschaft, Gesellschaft mit beschränkter Haftung.)

21377. Electric arc lighting. Vosmaer.

21381. Electric incandescence lamps. Lake. (Soc. de Commentry-Fourchambault et Decazeville.)

1900.

1618. Method of and devices for regulating or controlling electrical switches. Kingsland.

2710. Electricity meters. Mordey and Fricker.

5203. Lead presses for making plates for electric accumulators and the like. Thompson. (Accumulatoren und Elektricitäts Werke Act. Ges. vorm. W. A. Boese und Co.)

9397. Armatures for dynamo-electric machines. Heidel.

10319. Electric storage batteries. Fell. (Wiegand.)

11917. Method of and means for signalling, chiefly designed for submarine purposes. Lake. (Gray Telephone Company.)

NOTES.

Books Received.—We have received a copy of "Electrical Engineering," with particular reference to conditions in Bengal, by Mr. J. W. Meares, electrical engineer to the Government of Bengal. The book consists of six lectures delivered to native students at Sipur Civil Engineering College, and is published by the Bengal Secretariat Press.

Another Electrical Exhibition.—It is stated in the French Press that a proposition by the Société Electrotechnique of Vienna to hold an electrical exhibition in that town in 1903 has been received with great favour. Committees are already being formed, and numerous enquiries have been made as to the details of the exhibition. Everything apparently is to be done to make it a success, and the work of organisation has already commenced.

A Substitute for Coal.—It is, we learn, proposed to use the great beds of peat which exist in Northern Germany for the purpose of producing electricity on a large scale. There are about 1,000 square miles of peat area, and an enormous quantity of good fuel could be obtained therefrom. The fuel from this source should prove to be very cheap when compared with coal, and both producers and consumers would, we think, obtain some benefit from its use.

A New Fire Alarm System.—We notice that the Berlin Fire Brigade have been experimenting with a new system of fire alarms introduced by Messrs. Mix and Genest. The most important feature of the system, apart from its simplicity and reliability, is that with the aid of simple wire connections any number of private alarms may be connected to each public alarm pillar at a very low cost, whereby the fire brigade may be communicated with from a large number of points.

Spark Length.—With reference to the note under this heading in our last week's issue, Mr. H. W. Geare has forwarded to us the following results of some experiments conducted by him, and which are of considerable interest. He employed a two-plate Wimshurst machine with glass plates, the apparatus being arranged as described in our note. Without the glass tube he obtained a spark $1\frac{3}{8}$in. long, but on placing the glass tube just in front of the positive pole, facing towards the negative, the spark was 5in. long. The glass tube that answered best he found was about 8in. long and $\frac{7}{16}$in. diameter.

French Cables.—The French Cable Committee, at the end of their report to their Government on the feasibility of constructing lines of cables, suggests the following lines: a line to Tangiers, a length of 290 miles, at an estimated cost of £32,000; a line from Brest to St. Louis, 2,500 miles, at a cost of £680,000; a line from Hué to a point north of Hong Kong, about 1,000 miles, at a cost of £220,000; a line from Tamatave (Madagascar) to Réunion, 455 miles, at a cost of £72,000; and lines in the Benin Gulf and French Congo. These lines the commission urge should be started immediately. Other lines are mentioned for which the need is not so pressing.

Automobile Driving.—Mr. J. P. Collins, of Scranton, has invented a "twin motor" for driving and steering automobiles, in which the driving wheels turn independently of each other. The motor is of very light construction, having a single field casing with two parallel armatures which operate independently, and whose shafts may be connected to the independent driving wheels of the automobile, so that these wheels may be driven at the same speed to propel the vehicle in a straight line or at varying speeds for turning corners. There are, no doubt, several good points in connection with this motor, which is illustrated in the *Electrical World*, but we are inclined to think the advantages gained are hardly worth the extra cost of construction.

Russia.—According to reports to hand, the introduction of electric traction and lighting into South Russia is making rapid headway. A Belgian has obtained a concession to construct and work an electric tramway in the town of Poltawa. The necessary capital will be found by a limited company to be promoted in Brussels. It is intended to commence the construction of the line next spring. Further, the Belgian Street Railway Company in Odessa have obtained a concession to construct and work an electric railway in Winnitza, and to light the town by means of electricity for a period of 30 years. Not long since a cable works was opened in Kiew. At present it is producing only insulated wires for telegraph and telephone work, but later on it is intended to instal plant for the manufacture of electric light cables.

Electric Traction in Greece.—The United States Consul at Athens reports that the Athens to Piré Railway Company under its charter is bound to adopt within three years' time electrical driving on its line. The line runs from the Quai du Piré into the centre of the town of Athens. Its length will be five miles, of which three-quarters of a mile will be in a tunnel running under a portion of the town. A Belgian company owning a steam line between Athens and Piré is also desirous of adopting electricity, but has not at present arranged for the conversion. A large number of passengers are carried on each of the lines. The president of the first company will visit the Paris Exhibition to investigate the electrical machines shown, and to consider which is the best system of traction for the line he represents.

Indian Telegraphs.—The Telegraph Department of India has established a new record in telegraph construction. It has been recognised for a considerable time that the Indian Telegraph Department has done remarkably good work, and the latest report tends to confirm this. Thus the Indian correspondent of the *Financial News* states that a smart piece of work has been executed in the laying of the new line linking Bombay and Madras. Orders for the erection of the new telegraph wire from Bombay to Madras, a distance of about 800 miles, which was required in connection with the abnormal traffic with the Far East, were issued on July 7 last. Work was commenced on July 15, and concluded on Aug. 14. This is a result of which the Telegraph Department may be justly proud, and the good work of the officers and men engaged is recognised by the authorities.

Damaging Telegraph Wires.—Just retribution has fallen on a lad named David Pritchard, who has been amusing himself lately by throwing stones at telegraph wires and insulators in the Harewood End district. This is not the first time that the boy has got into trouble for the same offence, as he was let off last December on the understanding that his parents should punish him. The damage done consisted of the breaking of seven insulators, and if such damage were to continue it would be a constant source of annoyance to the telephone employés. After deliberating in private, the magistrate said the Bench believed defendant to be guilty, and this was a thing that must be stopped. He was liable to a fine of £10 or three months' imprisonment, but they would be lenient, and hoped defendant's father would look after him in future. He would be fined £1 including costs. This verdict will probably help the father to look after his son, but we think

Digitized by Google

a liberal application of the birch would have a more lasting effect on the boy himself.

Lift Accidents.—The lifts at the London Bridge Station of the City and South London Railway were again recently the scene of an accident. The lifts at this place seem to have lately been under repair, and this last accident, like the more serious one of a month or two ago, was apparently the result of carelessness on the part of the workmen engaged. The previous accident it was shown could easily have been avoided, and this one, in which a workman was caught between the lift and lower platform, could also have been avoided if care had been taken. It is a pity that accidents of this sort occur, as they do not tend to increase the trust which people should place in electric railways. One or two accidents of this kind are sufficient to deter many people from using the electric railways, and make it harder for this method of travelling to become popular with the public.

Range-Finding.—During the Spanish-American war, at the bombardment of Santiago, the range-finding apparatus used by the Americans broke down, and became practically useless. The guns on which these range-finders were used were naval guns, and the *Electrical World* comments to the effect that the high-power mortars, for which the United States alone seems to have a preference, were not supplied with range-finders at all. The big guns were also without them, and consequently half their usefulness must have been taken away. In this matter our contemporary thinks that electricity should be brought to the aid of the gunner, and the range-finders now used might be greatly improved. From what we have ourselves seen of range-finders on this side of the water, we should say that much less delicate and, at the same time, quite as accurate instruments might be constructed as those now used. The time taken in getting the instrument properly placed, and the trouble experienced in keeping it in position afterwards, are great drawbacks to its use. The *Electrical World* also suggests that motors might be used to elevate and depress large coast-defence guns, and to turn them on the firing platform, as is done on ships in the Navy.

British Institution of Draughtsmen.—On the 7th inst. the members of the Manchester branch of the above institution visited Blackpool for the purpose of viewing the Corporation electric light station and the generating station of the Blackpool and Fleetwood Tramway Company. The former was especially interesting, owing to the various types of generators employed, which included Ferranti flywheel type, Fowler horizontal engines, driving by ropes Fowler alternators and Parsons turbo-generators. The latter type are also used for generating the continuous current for driving the cars. The turbines and the Ferranti rectifiers received marked attention from the visitors. It was noticed that extensive alterations are in progress, including what promises to be an unusually large chimney-stack. The members were much indebted to Mr. Robert C. Quin, the borough electrical engineer, for his kindness. The generating station of the Blackpool and Fleetwood Tramway Company was also interesting, owing to its symmetry and compactness. The visitors were received by Mr. MacMahon, who kindly explained the points of interest. The plant consists of five combined sets of 150 kw. each by Mather and Platt, and has run since its installation without any mishap.

Automatic Issue of Tram Tickets.—Several of our German contemporaries describe an electrically-actuated device designed by Herr Fritz Krull for the automatic issue of tickets on tramcars. The Germans have long since come to the conclusion that it lies in the interest of the tramway companies to issue tickets to the passengers travelling over their lines through the medium of reliable automatic machines, rather than through conductors. This applies not only for short lines with an infrequent service of cars, where conductors can well be entirely dispensed with, but also for lines upon which a conductor is necessary, owing to the frequent service of cars. In the latter case the employment of apparatus for the automatic issue of tickets to passengers enables the conductor to devote his whole attention to the control of the traffic, thereby enhancing the safety of the service. But hitherto attempts to introduce automatic ticket sellers on the electrically-worked lines have been unsuccessful, owing to the inability of such apparatus to withstand the violent shakings and concussions to which it is subjected. The latest device, however, is claimed to overcome this objection, and to satisfy every other requirement, even down to rejecting base coin.

The Electrolytic Production of Gases.—In an article contributed to the *Zeitschrift füer Elektrotechnische*, Herr M. U. Schoop considers the commercial production of oxygen and hydrogen by electrolysis, with special reference to the use of oxyhydrogen gas for soldering purposes. What appears to be a very efficient water electrolyser, of German design and manufacture, is described in the course of the article. In his concluding remarks the author compares the well-known disadvantages attending the production of hydrogen by chemical means with the advantages claimed for the electrolytical generation of the same. These latter, apart from the relative cheapness of the process, consist in that hydrogen produced by electrolysis, owing to its ideal purity, enables a flame of far more intense heat to be obtained, whereby quicker work and better soldering are rendered possible, while at the same time the gas gives off absolutely no fumes calculated to injure the health. It is further pointed out that with the exception of replenishing the electrolysers with water once in every 14 days, the apparatus requires no attention whatever. Having regard to these distinct advantages, Herr Schoop thinks there should be little difficulty in deciding to which process to give the preference.

Photographic Exhibitions. — We have received notices of the holding of two photographic exhibitions. The first, that of the photograhic salon, is to be held at the Dudley Gallery at the Egyptian Hall from Sept. 21 till Nov. 3. This is the eighth year of this exhibition, and the aim of the committee is stated to be to exhibit only that class of work in pictorial photography in which there is distinct evidence of personal artistic feeling and execution. The other exhibition, that of the Royal Photographic Society, is to be held from Oct. 1 to Nov. 3 at the New Gallery, at 121, Regent-street. This will be the forty-fifth annual exhibition, and it will be inaugurated on Sept. 29 by a private view followed by a conversazione. The exhibition will be opened on weekdays upon the days named from 10 a.m. to 6 p.m., and on Monday, Thursday, and Saturday evenings from 6 to 10 p.m. On these evenings lantern slide exhibitions are to be given. The admission at any time will be 1s. The exhibition will be divided into five sections—viz.: pictorial photographs; general professional work; photographic apparatus and material; photomechanical processes of reproduction; and scientific photography and photography in its technical applications. This exhibition, unlike the one previously noticed, will be a competitive one, and medals will be awarded for the best work.

Transformers.—Various proposals have been made, says the *Elektrotechnische Rundschau*, to employ stationary

Digitized by Google

armature coils and commutators for the conversion of alternating currents into continuous currents, by generating a rotary field in the armature and revolving the brushes. With regard to construction and efficiency, such an arrangement would offer many advantages, especially in that its magnetic lines in the stationary armature could have a closed path, and it would, moreover, be required to set small masses only in motion. That this method of transforming has hitherto found no practical application worthy of note must be attributed mainly to the fact that the collection of the transformer current, which, according to the proposals hitherto made, would have to be accomplished by means of revolving brushes bearing upon slip rings, presented great difficulties. The "Helios" Company, of Köln-Ehrenfeld, have, however, surmounted these difficulties by constructing a transformer with a stationary armature, in which the continuous current yielded is collected from points of the armature winding or of the transformer winding, which excites the armature, in either case, therefore, from stationary points. In this manner the function of the brushes becomes of minor importance, while the construction and arrangement of the brushes is simplified and the use of slip rings avoided.

Electricity v. Gas.—The *Electrical World* of New York publishes a summary of the convention of the Ohio Electric Light Association which was recently held at Toledo in that State. Amongst the papers, which seem to have been generally of a very instructive nature, was one by Mr. W. F. White, of the Cincinnati Edison Company, discussing the relative merits of gas and electricity for street-lighting. The gas lighting, with which electricity was compared, was with Welsbach burners. In his paper Mr. White stated that electricity was received with universal favour for public lighting. About 60 per cent. of the cities in the United States with populations of over 25,000 were shown to have adopted electricity, and the other 40 per cent. were rapidly reaching the same point. It was, he stated, shown that electric lighting was cheaper, in that the lighting companies provided all the equipment, in addition to the much better lighting of the streets. In order to show the advantage in extra illumination, photographs were shown of street-lighting with Welsbach lamps and those lighted with electricity. In the paper Mr. White states that one arc lamp of 800 useful candle-power gives as much light as 20 Welsbach lights of 40 useful candle-power. The photographs of the streets lighted electrically, it is interesting to note, were exposed for 12 minutes, while with the Welsbach lights considerably over 20 minutes was needed to get any picture at all.

The Central London Railway v The 'Buses.—The *Financial News* published recently a comparison of the takings of the London General Omnibus Company and the London Road Car Company on certain days of last and the present months with those of the corresponding days last year. The comparison was made in order to show the effect which the Twopenny Tube has had on the receipts of the above-mentioned companies. There can be doubt but that this effect is considerably felt, and will probably be felt still more in the wet and cold days which are not so far hence. Nothing could be more natural than that the electric railway should take away a large number of 'bus passengers. In the first place, the fare is much cheaper and the journey is accomplished in a much shorter time. One also remembers the discomforts of sitting either inside or outside of a 'bus in wet weather, and again the tube seems more attractive. In the five days for which figures are quoted the average drop in receipts per day by the Road Car Company is about £740, while with the General Omnibus Company it amounts to about £1,360. It is interesting, however, to note that the securities do not show much indication of the competition, as when the Central London Railway was opened London General stock was 170-180, and is now about five lower at 165-175. London Road-Car shares were then selling at 8½-9½, and are now about 8-9.

Wireless Telegraphy.—Mr. Marconi it appears is not to have a monopoly of wireless telegraphy, as other inventors appear to be making great efforts to outshine him. His latest rival is Prof. Rosenberg, who has invented a system with which he communicates from office to home, etc. It is stated that the system is yet in its infancy, but its inventor promises great things for it. When one wishes to be in communication with home or office, one has to carry a receiver with him. At present this would be rather a burdensome task, as the receiver is a rather cumbrous object. Prof. Rosenberg is, however, going to reduce it to pocket size, and then one can go anywhere within a certain radius, and still know what is going on at home. The inventor, who recently gave a demonstration of his instrument at the Crystal Palace, claims to have greatly improved on the Marconi system. He can transmit messages 40 miles or more through the air, and can also intercept other wireless messages. He claims to have done this on Hampstead Heath, but the persons communicating were evidently prepared for him, as he seems rather disappointed to find that they were either sending nonsense messages or were using a code with which he was unfamiliar. The exhibition at the Crystal Palace does not seem to have been such as to make the shareholders in the Marconi Company despair entirely, but we await the promised further development of Herr Rosenberg's system with interest.

A New Telephone System.—The new system of telephones recently brought out by the North Electric Company, of Cleveland, is worthy of mention. It is of the central battery type, having signalling equipment located at the central office, and being arranged so that the subscriber calls up the operator automatically by lifting the receiver from the hook. On the removal of the receiver an automatic gravity-restoring line signal is shown at the switchboard, indicating that a call is wanted. The operator, by inserting the answering plug, also automatically restores the line signal and establishes connection. On inserting the calling plug to call the subscriber required both the operator's and caller's sets are switched out while the generator current is on the line. In connection with each side of the cord circuit is a supervising signal, indicating when the talking is finished. The operator never has to cut in on the line to ascertain whether the conversation is ended, and at no time has she to use the line except to ask the number required. The North Electric Company claims with respect to this "supervisory" system that there is no centralised battery system having so small a battery consumption as there is in the regular operation of this system. In fact, it is to be perfectly practical in most exchanges to use ordinary closed-circuit types of batteries. This is an important feature to be considered when making out estimates of the maintenance expense of an exchange. A very neat and efficient power plant is provided, and also an alarm relay giving an automatic signal at any time an exceptional drain on the batteries occurs. It is also claimed that an operator with this system can take charge of a considerable larger number of lines than with the old magneto-call type.

Electric Railways in the States.—The extent of the development of electric street and other railways in the United States has been recently shown by a report of the United States commissioner of patents. The report,

Digitized by Google

which appears in *Cassier's Magazine*, states that the first electric street railway in the United States was put in operation little more than 10 years ago. In 1880, of the 2,050 road miles of street railway in the country, nearly all employed animal power. Electric power had not yet come into use, but a few miles of lines were operated by steam and by cable. The total number of persons then employed on American street railways was very nearly 12,000. Ten years later, in 1890, the United States census gave the number of street railway employés as 37,434, and at the close of that year the total mileage of street railways all over the country was given as 8,123 track miles, on 5,661 of which horses were used, while the remaining 2,493 miles were worked mainly by electric and cable power. The capital invested in these roads was about £42,255,558, and 71,000 persons were employed by them. In 1894 the total mileage was 12,527, of which 7,470 was electric. The capital invested was £129,666,151, of which £84,698,644 were invested in electric railways. One hundred and ten thousand persons were employed on street railways in that year. In 1896 the mileage had increased to 14,470, of which 12,133 miles were electric. The capital invested was £156,962,756, and the number of persons employed was over 140,000. The total mileage of electric railways in the United States up to October of 1897 was 13,765 miles, out of a total mileage of 15,718, and of these but 947 miles were horse-car lines. The total capital invested was £169,226,338, and the number of employés over 166,000.

Resistance of Thin Films.—Mr. A. C. Longden in the August number of the *Physical Review* continues his notes on the "Electrical Resistance of Thin Films deposited by Kathode Discharge." The instruments for measuring the resistance which were used in these experiments were exceptionally accurate, and had a wide range. Beyond this range the resistance was measured by the direct deflection method. In applying this method a new form of water battery was used, consisting of two copper plates, one of which was amalgamated with mercury containing a little zinc. This plate was equivalent to a zinc plate, but it did not dissolve in the cell or become brittle like zinc plate does. The resistance of this cell may be varied with its size, or by the introduction into the water of a very small quantity of sulphuric acid. The cell, if properly made and sealed, requires no attention for many months, and its E.M.F. is practically constant. It, however, polarises very quickly, and is only of use on high-resistance circuits. In measuring the temperature coefficients of film resistances, it was soon noted that the very thin films had negative temperature coefficients, and all the thick ones had positive temperature coefficients, and that for a certain range of thickness the temperature coefficients were almost at zero. Density also probably helped to produce this zero result. The length and width of all films tested were uniform, being 5cm. by 15mm. The author then describes the process of adjusting and standardising the film resistances, the choice of a metal for the production of standard film resistances, etc. The metal he chooses for the standard is platinum. His conclusions, stated briefly, are as follows: The process of depositing metals by kathode discharge is probably simple distillation, in which the vaporisation of the kathode is largely due to its electrification; the temperature coefficients of the very thin films are negative, and for films within a certain range of thickness the temperature coefficients are approximately zero; the necessity for artificial ageing is proportional to the magnitude of the temperature coefficient. He states that in general his method is capable of producing standard electrical resistances of a very high degree of precision, and of any desired value, from a few ohms up to several megohms; that these resistances may be made of pure metals, and that they are therefore free from the possibility of decomposition changes; that the metals may be those least likely to enter into chemical combination with other elements; and that, in addition to these qualities as pure metals, they possess the only desirable qualities of alloys—namely, high specific resistance and low temperature coefficients.

Rubber.—We notice in various American papers a report by Mr. O. J. D. Hughes, United States Consul at Coburg, on the German rubber trade. In this report he states that the import of crude rubber into Germany in 1899 amounted to over 13,000 tons an increase of over 50 per cent. in value over those of the year 1897. The exports of raw material amounted to nearly 5,400 tons, estimated at about £143,000. The United States Consul in Sierra Leone, in reporting on the rubber industry in that colony, says that the supply to Freetown market mostly comes from the hinterland of Sierra Leone and from the French protectorate further in the interior. This latter is, however, limited, owing to the export tax of about 1½d. per pound which is placed by the French on all rubber sold by natives outside the protectorate. This rubber though nearly always adulterated with clay, yet commands a high price. As in South America the natives in Sierra Leone bleed the roots of the trees occasionally in order to increase their stock. This kills the trees, and at the same time the rubber obtained is of a very inferior quality. In buying the rubber from the natives great care has to be taken by the agent with respect to adulteration. There are two classes of this, incidental and intentional. The former is the result of carelessness on the part of the gatherers, who do not use proper receptacles for the juice. Intentional adulterations are due to efforts to increase volume and weight by use of dirt, sand, bark, and sometimes stones. Another species of fraud is the mixture of other non-elastic gummy substances with pure juice; still another is to soak rubber by placing it in pits close to the water for a long time. Rubber so treated is seriously injured in quality, and at the same time increased in bulk and weight. The colonial authorities, as well as the chambers of commerce, are endeavouring, by proper instructions to those concerned, to discourage these abuses, and to emphasise in every way possible the importance of improving the quality of the rubber brought to Freetown Market. There is being inaugurated by the governor and officials a plan to foster the planting of rubber trees and vines in the colony. To this end they have caused to be issued pamphlets of instructions in regard to seedings, transplanting, etc., through the departments of agriculture and horticulture. It is hoped that there will be a decided improvement in the quality and quantity of the exports in the near future. The value of the rubber exported from Sierra Leone in 1898 was about £51,000, of which the amount shipped to Germany was £6,700, the remainder going to England.

Popularising Electricity.—In a recent number of the *Universal Provider* is an article dealing with the question of increasing the popularity of electricity for lighting purposes amongst the ordinary public. Up to quite recently the use of electricity for lighting was confined to shops, offices, etc., there being comparatively few places in which it was used in residential districts. Many of the causes of this state of affairs have now been removed, and the ordinary gas-using householder could with great advantage to himself in most of the larger towns change over from gas to electricity. The unreliability which in past years greatly militated against the success of

Digitized by Google

electricity as an illuminant has practically been done away with, and it is only on rare occasions that inconvenience is caused owing to the failure of the light. The cost of electricity has also in recent years decreased some 40 or 50 per cent., and it can be now obtained in most cases more cheaply than gas. In the fittings also great improvements have been made, and instead of the old expensive, badly-made, and short-lived fittings, we now have articles which are almost perfect. The initial cost of wiring and fitting houses is even now somewhat heavy, but in a number of cases the fitting and wiring is done by the company or municipality, and the cost repaid in the same way that the free gas fittings are. This, however, sometimes comes rather heavy on certain consumers, and a plan has in certain instances been adopted whereby the landlord or householder obtains an estimate from a local contractor. If he desires hire purchase he submits his scheme to the lighting corporation, who, on the condition that the consumer undertakes to wipe off the amount in a certain number of quarterly sums, pays the contractor, less 5 per cent. for cash. The installation is afterwards maintained by the consumer. This system seems to be fair to the lighting companies, local contractors, and customers alike, and has the merit of simplicity. In cases where tenants occupy premises under agreements for short terms the landlord is made a party to the contract, so that the wiring becomes his property on the cessation of the tenancy. As regards meters, there seems to be a tendency on the part of those who supply the current not to follow the example of the gas companies in charging rent for their use. This seems but fair, as it is hard to see why the consumer should have to pay for having the current measured for the convenience of the supply corporation in making up their bills. Much might be done also by vestries and corporations if they laid new mains in their newer districts and wired numbers of new houses on the off-chance of securing their owners as customers. The investments in the face of the above facts would probably prove very successful.

An Interesting Scheme.—Some particulars of an interesting scheme now in course of execution for the supply of Lausanne with electricity for lighting and power purposes were given in a recent issue of the *Schweizerischen Bauzeitung*. The most noteworthy feature in connection with the undertaking is that the energy will be transmitted in the form of high-pressure continuous current over a distance of 56 km., and afterwards distributed in the form of three-phase current to consumers in Lausanne. The generating station will be situated near St. Maurice, in the upper valley of the Rhone, which river will furnish the motive power for driving the generating plant. At the point selected the available fall of water varies between 34·5m. and 36m., which yields a minimum of 6,000 h.p, while during 10 full months of the year 14,000 h.p. may be obtained. The initial instalment of plant will comprise five turbines with horizontal shafts, each capable of developing 1,000 effective horse-power when running at 300 revolutions per minute. To each of these turbines will be direct-coupled two continuous-current dynamos, designed to yield a constant current of 150 amperes. These 10 generators will be connected in series according to the immediate requirements of the load, a maximum line pressure of 22,000 volts being available with all the generators so connected. The terminal potential will be maintained constant by automatic regulation of the speeds of the generators. The constant current generated will be conveyed by means of two bare conductors of each 150mm² sectional area to Lausanne, 56 km. distant from the generating source. The loss of energy in these conductors is not to exceed 300 kw.—that is to say, one-tenth of the full load. In the immediate proximity of Lausanne a transformer station is to be erected. This will contain at first five continuous-current motors coupled in series, and driven by the current generated by the plant in St. Maurice. These motors will each have a capacity of 400 h.p. running at a constant speed of 300 revolutions per minute. They are destined to drive three-phase generators of equivalent output, with a line pressure of 3,000 volts—that is to say, 1,730 volts in each phase. Two of these groups of transformers are to be supplemented by vertical steam engines of 400 h.p. each at 300 revolutions per minute to serve as a reserve. By means of the latter provision it will also be possible to inaugurate the supply of electrical energy to consumers before the installation in St. Maurice is completed. The three-phase current will be distributed by means of underground cables to some 30 transformer substations situated in various parts of the town, in which the pressure will be reduced to 125 volts for final distribution to consumers.

Terrestrial Magnetism.—We notice in Mr. Carl Hering's digest in the *Electrical World* an abstract of a paper read by Mr. Sutherland on "Earth's Magnetism" before the Australasian Association for the Advancement of Science. The author states that a possible cause of the earth's magnetism is the rotation of an electrostatic field within the earth. He treats analytically the case of a sphere revolving around a central axis and charged with electricity of a given surface density; he shows that the formula of the magnetic field in this case has exactly the same form as that of the potential for a uniformly magnetised sphere, or for a sphere with an infinitely short magnet of finite moment at its centre. To account for the magnetic field of the earth, the electrostatic surface density has to be 51,000 electrostatic units; such a charge would produce an enormously strong electrostatic field at the surface of the earth, for which there is no evidence. But if we imagine the equal and opposite electric charge gathered at the centre, it would completely neutralise the electrostatic field due to the surface charge, while by being at the centre it would fail to affect the magnetic field of the surface charge. This gives an ideal model of the earth's magnetic field as produced by the rotation of a powerful internal electrostatic field; the magnetic field outside the earth would be the only external evidence of the existence of the electrostatic field within. Calling the field got by averaging round circles of latitude the primary, and the residual field which causes the want of coincidence between magnetic and rotational axes the secondary, our possible cause for the primary is such as will prevent the primary field from sharing in the earth's rotation. Thus the substance of the earth revolves through a magnetic field which is as fixed as if derived from fixed external magnets. The earth, with magnetic material in it and with a conducting crust, is somewhat like a dynamo armature revolving in the field of the exciting magnets. The magnetic material intensifies the primary field of the last section by magnetic induction, and if the permeability is unsymmetrical the induced field may not lie in the same direction as the inducing. The actual obliquity of the magnetic to the rotational axis is therefore traced to unsymmetrical magnetic permeability of the earth, which also causes the induction of the earth currents, the secular variation of whose tracks is the cause of the magnetic secular variation. The theory advanced by the author to account for daily variation is that under the action of the sun's rays the oxygen and ozone of the atmosphere become the active substance of a large secondary battery whose alternate charge and discharge are the cause of the daily variations.

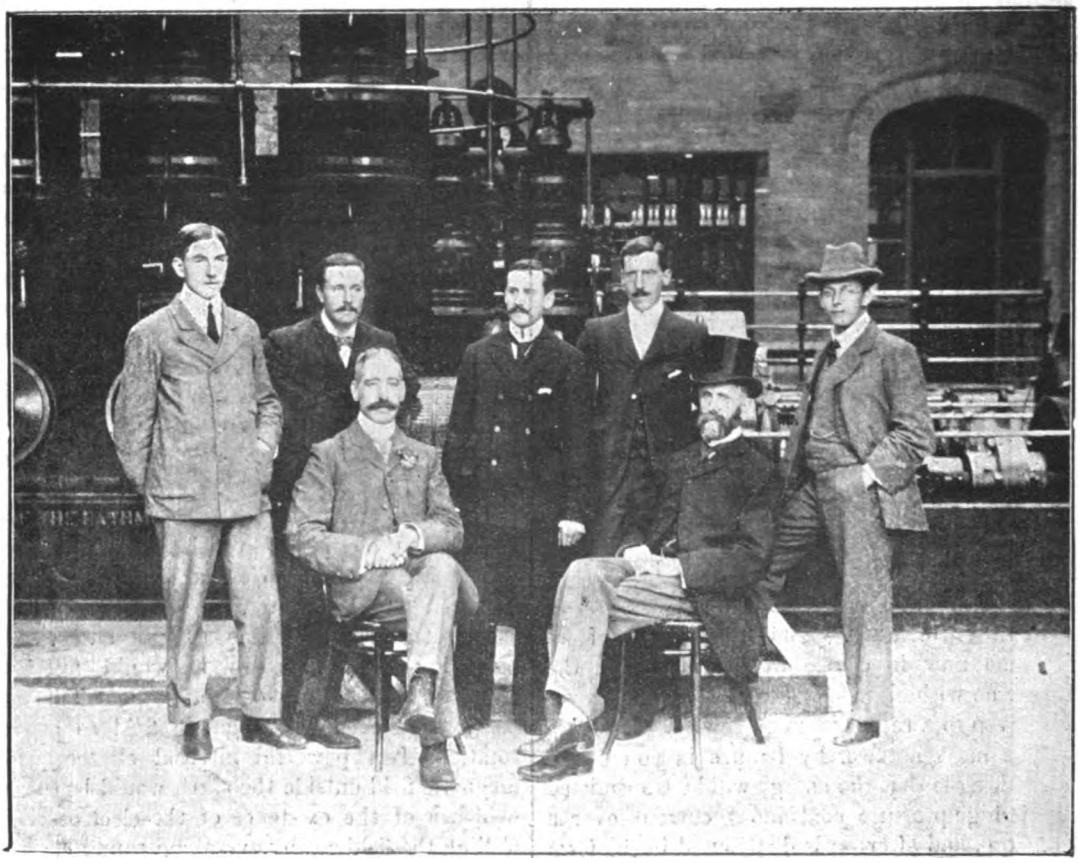
RATHMINES MUNICIPAL ELECTRICITY WORKS

The question of providing a supply of electricity for Rathmines first received practical attention in 1895, when, principally owing to the exertions of the late Mr. Samuel H. Bolton, J.P., a special committee was appointed to consider the advisability of establishing a municipal supply. It was the general feeling that the work should be undertaken by the local authority—then the Rathmines and Rathgar Improvement Commissioners—and as a first step towards the realisation of the project the Commissioners authorised the committee to make application to the Board of Trade for a provisional order under the Electric Lighting Acts. The result was the granting of the Rathmines and Rathgar township electric lighting order in 1896, the Royal assent to the confirmatory Act being accorded on July 20 of that year. In the meantime the Commissioners had consulted Mr. Robert Hammond, of Westminster, as to the best means of fulfilling their statutory obligations under their order. At the same time the committee devoted themselves to an energetic investigation of the practical issues of the project, and although rather a long interval took place between the granting of the order and the decision to proceed to lay down the works, the time was not ill-spent, since it enabled the committee to take advantage of the experience that was afforded by the successful operation of many electricity works that had been established by municipal authorities. In July, 1898, Mr. Hammond was authorised to prepare the necessary plans and specifications for the generating works and mains, and tenders for the various sections of the work were publicly invited in the following year. These were carefully examined by the committee, and on their recommendation the Council eventually gave out the contracts as follows:

R. Taylor and Sons, Marsden, Yorks, boiler-house plant.
Mather and Platt, Manchester, engine-house plant.
J. Spencer, Limited, Wednesbury, pipework.
Wheeler Condensing and Engineering Company, U.S.A., condensing plant.
Klein Engineering Company, Manchester, water-cooling plant.
Higginbottom and Mannock, Manchester, travelling crane.
James White, Glasgow, switchboard and testing instruments.
Tudor Accumulator Company, London, accumulators.
British Insulated Wire Company, Prescot, supply mains (insulated cables and trench work).
S. Z. de Ferranti, Limited, Hollinwood, house meters.
Verity's, Limited, Birmingham, arc lamps for public lighting.
General Electric Company, London, incandescent lamps for ditto.
J. Donovan, Dublin, buildings.

System of Supply.—The direct-current three-wire system is employed, energy being supplied to consumers at a standard pressure of 220 volts for lighting and for small motors, and 440 volts for motors requiring more than 5 kw.

Site of Station.—The generating works are situated in a convenient central position on the Council's land at the rear of the town hall, where adequate space for extension is available. The buildings form a substantial structure of brick and stone, and comprise engine and boiler houses, battery and test rooms, engineers' offices, stores, and workshops. The engine-house is 37ft. wide, the length from the wall at the back of the switchboard to the temporary end being 48ft. Parallel with it is the boiler-house, and on the opposite side are the workshops and the chief assistant's offices. The battery-room, test-room, and general offices form the front part of the group.



RATHMINES ELECTRICITY WORKS.

MR. L. L. ROBINSON.

MR. R. DEENE BOLTON, Chairman of the Electric Lighting Committee.
MR. F. P. FAWCETT, Clerk of the Council.

Boiler-House Equipment.—The steam generating plant comprises three Lancashire boilers, made by Messrs. Robert Taylor and Sons, of Marsden, each 30ft. long and 8ft. in diameter. They are constructed of six rings of mild steel, and have an evaporating capacity of 7,000lb. of water per hour at a pressure of 160lb. per square inch with the feed water at 60deg. F. Regular firing is secured by mechanical stokers of Messrs. Vicars's manufacture. The flue dampers are handled from the boiler front by means of counter weights sliding in guides calibrated to show the extent of the opening. A full complement of safety fittings, valves, and gauges were supplied by Messrs. Hopkinson. The lagging of the boilers with fossil meal to a depth of 3in. was undertaken by Messrs. Haacke and Co. A double-ram steam-driven pump by Green's, a Holden and Brookes

Digitized by Google

injector, and an electric combination consisting of a Lundell motor with a three-throw single-acting pump by Blake and Knowles, are provided to deal with the feed water. The steam and feed pipes are of lap-welded steel, the latter galvanised, and the lagging is of sectional magnesia covering. The contract for the pipework, including the erection of the cast-iron feed tank and the feed-water heater, has been carried out by John Spencer, Limited, of Wednesbury. For the purpose of heating the feed water on its way to the boilers, one of Green's economisers, containing 96 tubes, has been erected in a by-pass from the main flue between the boilers and the chimney stack, and is capable of easy enlargement when required. The scrapers of the economiser and the mechanical stokers are operated through belting by an iron-clad 6-b.h.p. motor from Messrs. Crompton and Co.'s works at Chelmsford. Fig. 1 gives a good view of the boiler-house and arrangement of feed pump, pipes, etc.

Engine Room Plant.—In the engine-room (Fig. 2) there are two sets of generating plant, one of 300 kw capacity and the smaller of 150 kw., the two being capable of supplying electrical energy for about 22,500 lamps fixed on consumers' premises. With the aid of the accumulators the demands of 30,000 lamps could be dealt with. Each set consists of a pair of four-pole direct-current Mather and Platt dynamos, driven by a Willans central-valve engine. The larger engine has three cranks and nine cylinders, and runs at 320 revolutions per minute. The smaller engine has two cranks and four cylinders, and deals with its maximum load at a speed of 360 revolutions per minute, the working steam pressure being 150lb. to the square inch. Steam separators are fitted to each engine, and lubrication is effected automatically. The guaranteed steam consumption at full load when running condensing is 24½lb. per kilowatt-hour for the 300-kw. plant and 29lb. for the 150-kw. set. A Mather and Platt motor-generator is provided for the charging of the regulating cells of the battery of accumulators. A jet condenser with a steam-driven direct-acting pump has been fitted in the cellar by the Wheeler Condensing and Engineering Company. It maintains a vacuum of 26in., and raises the water to the top of a Klein cooling tower, where it is reduced in temperature by about 30deg. F. This tower cooler uses natural draught, and is able to deal with 40,000 gallons of water per hour. The engine-room is traversed by a 10-ton crane supplied by Messrs. Higginbottom and Mannock, of Manchester.

Switch Gear.—The switchboard (see Fig. 2), surmounted by an electrically-wound clock, is situated on a platform at the end of the engine-room, and stands upon a plinth of glazed bricks 18in. high. Its length is about 17ft. The board is divided vertically into three panels, the arrangement being as follows:

Positive Panel.	*Centre Panel.*	*Negative Panel.*
Feeder ammeters.	Voltmeters.	Feeder ammeters.
Feeder switches.	Battery regulators.	Feeder switches.
'Bus bars.	Booster switch and ammeter.	'Bus bars.
Dynamo ammeters.	—	Dynamo ammeters.
Dynamo switches and regulators.	Neutral bar.	Dynamo switches and regulators.

The necessary labels are provided in three distinct colours, indicating the purpose and polarity of each piece of apparatus. Provision has been made on the outside panels for four dynamos and for nine three-wire feeders, also for the main circuit of the battery. The centre panel carries the electrostatic voltmeters for the "pilots" and battery, together with the ammeters for the "neutral" and the earth mains, together with a protective device to short-circuit the earth current recorder. In each dynamo circuit is a minimum cut-out, an ammeter, a two-way switch and fuse, and a shunt regulating switch. One polarised voltmeter serves each pair of dynamos. Each feeder has two ammeters, with duplex switches and fuses fixed on the upper half of the outer panels. A chamber below the switchboard contains the neutral bar and the registering watt-hour meters on Aron's three-wire system. The battery is arranged to be charged by the booster in conjunction with the generators. A multiple contact switch for regulating the supply when taken from the accumulators is situated in the accumulator-room, and is operated through rods and chain gear from hand-wheels fitted at the bottom of the centre panel of the switchboard. The booster gear consists of an ammeter and double-pole two-way switch and fuse, with a starting switch for the motor side. A Crawley automatic switch protects the dynamo of the booster, and a double shunt regulator permits the insertion of a variable resistance into the field-magnet circuits. Messrs. J. White, of Glasgow, the sole makers of Lord Kelvin's instruments, erected and connected up the board and made all the apparatus thereon excepting only the watt-hour meters.

The Accumulators.—The battery consists of 274 Tudor cells, each cell consisting of six positive and seven negative plates in a lead box. They are arranged in two tiers upon

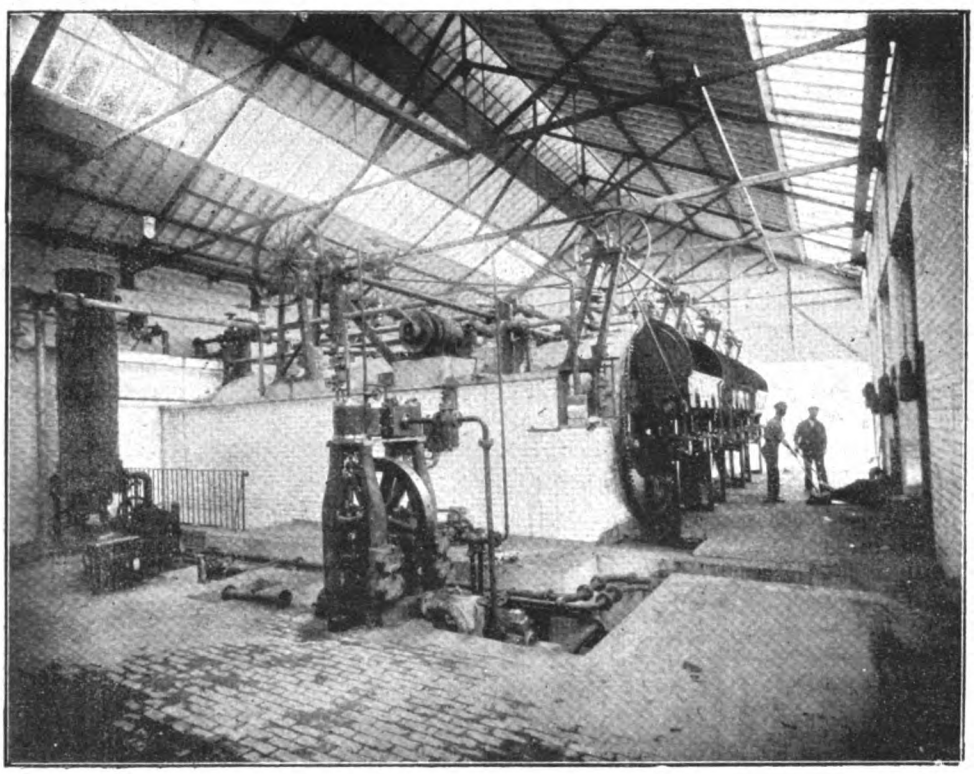

FIG. 1.—View of Boiler-House, Rathmines Electricity Works.

Digitized by Google

stout oak frames, which are protected from acid spray by a coating of special paint. Forty-nine cells on each side of the neutral wire serve as regulators, and are connected in steps to the steps on the regulating switch by bare copper rods. The battery is capable of discharging 80 amperes for 10 hours with a terminal E.M.F. of 500 volts. The normal and maximum rates are 120 and 150 amperes "on charge," and 80 to 216 on "discharge" respectively.

Distribution.—The whole of the work connected with the manufacture and laying of the cables has been carried out by the British Insulated Wire Company. The solid system has been adopted, all the feeder and distributor cables being triple-concentric paper-insulated and lead-sheathed. They are laid in cast-iron troughing filled in solid with pitch tempered with resin oil. For the distributing network ·10 and ·05 square inch cables have been laid, the outer conductor forming the "neutral" of the three-wire system. There are at present seven feeders, comprising ·4 and ·3 square inch cables. For the public arc lamps $^{7}/_{16}$ single cables are used, while concentric cables are employed for the incandescent street lamps and for house connections. Altogether 45 miles of cables have been laid. This does not include the pilot wires, which are laid in the same London and Dublin. They are connected through a switch and fuse in the base to the distributing network.

Scale of Charges.—Under their electric lighting order the Council are authorised to charge as much as 8d. per unit for electricity, but with the object of placing the supply at the disposal of all classes of consumers the Council have adopted the following moderate rates: 6d. per Board of Trade unit for private lighting and 3d. for power and heat. A discount of 5 per cent. is allowed off the above-named figure which brings down the prices approximately to 5¾d. per unit for lighting and 2¾d. for power. It is generally accepted that one unit of electricity is equivalent, light for light, to a little more than one-eighth of 1,000ft. of gas, so that electricity at the net price of 5¾d. per unit charged by the Rathmines Council for lighting can be obtained at practically the same cost as gas when the price of the latter is 3s. 8d. per 1,000 cubic feet. For motive power the price of 2¾d. per unit is equivalent to gas at about 1s. 10d. per 1,000 cubic feet. For the benefit of those consumers who do not care to expend the necessary capital in installing the wires and fittings in their premises, the Rathmines Electric Lighting Committee have adopted the free wiring scheme of the National Electric Company, of London. Upon the

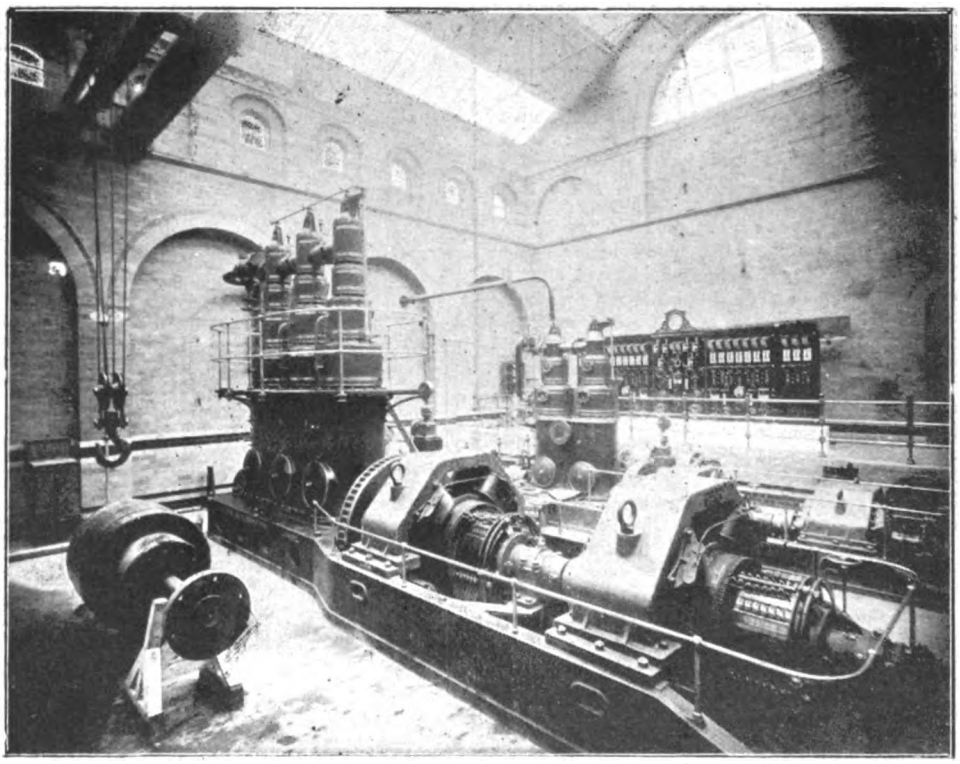

FIG. 2.—View of Engine-Room, Rathmines Electricity Works.

troughs as the feeders. The insertion of cast-iron junction boxes at numerous points facilitates the isolation of any section of the distributing network, either for repair or connections.

Public Lighting.—Arc lamps to the number of 108 have been fixed in the principal thoroughfares, spaced about 65 yards apart, and carried at a height of 18ft. from the roadway by cast-iron pillars with an ornamental curved bracket of wrought-iron construction. The lamps were made by Messrs. Verity, and the posts by James Allen, sen., and Sons. The arc lamps are run in 12 series of nine lamps each, connected across the outers of the distributors. The extinguishing of one or more lamps will not affect the remainder, as an automatic switch is provided to substitute a wire resistance for the lamp. The terminal lamps on each series are fitted with single-pole switches and fuses. All the lamps are provided with substitutional switches. Lowering gear enable trimming operations to be carried out from the roadway. Lighter and shorter posts, 230 in number, each bearing a two-arm bracket carrying a pair of incandescent lamps, deal with the lighting of the quieter streets. These were cast by Macfarlane and Co., and were fitted up and erected by the General Electric Company, of

application of an intending consumer, the wiring company provides and fixes on the premises the necessary wires and fittings, and completes the installation ready for connection to the District Council's supply mains. No charge is made for this work, but the consumer has to pay to the Council by way of rental for the wires and fittings the sum of 1d. per unit for every unit of electricity energy used, this sum, of course, being additional to the amount of the charges made by the Council for the electrical energy supplied.

Area of Supply.—The area of supply constitutes the whole of the district of Rathmines and Rathgar, the following being the names of the streets in which the Council's mains have been laid, and throughout which a supply of electricity is available: Belgrave-road, Belgrave-square North, Belgrave-square East, Brighton-road, Bushey Park-road, Castlewood-avenue, Charleston-road, Church-avenue, Cowper-road, Dartmouth-road, Frankford-avenue, Grosvenor-road, Harolds Cross-road, Kenilworth-road, Kenilworth-square North, Leeson Park-road, Leeson-street (Upper), Leinster-road, Upper Mount Pleasant-avenue, Lower Mount Pleasant-avenue, Mount Pleasant-square South, Orchard-road, Orwell-road, Palmerston-road, Ranelagh-road, Rathgar-road, Rathmines-road, Upper Rathmines-road,

Digitized by Google

Temple-road, Temple-gardens, Terenure-road, Winnefield-road, Zion-road. An extension of the mains to other parts of the district has already been decided upon, and the contract will shortly be given out for the probable requirements over the next three years. The Council will therefore be able to lay down mains in any other street where the demand is likely to yield a reasonable return on the capital expenditure on that section of the mains.

At present there are about 1,160 lamps of 8 c.p. connected, while applications for a further 3,050 lamps are in hand. In addition to these, the public lighting represents about 2,540 8-c.p. lamps, the total demand thus being equivalent to 6,750 lamps. A temporary supply has been given for the past month free of charge.

The capital cost of the generating works, mains, and public lamps amounts to about £71,000.

The whole of the works have been carried out under the supervision of Mr. Robert Hammond, the consulting engineer. Mr. G. F. Pilditch, who has acted as clerk of the works for Mr. Hammond, is now the resident electrical engineer, Mr. S. T. Land being his chief assistant.

Formal Inauguration.—The opening of the above-described works took place on the 31st ult. in the presence of a large and fashionable gathering. The function was performed by the Lord-Lieutenant of Ireland, who was received, together with Countess Cadogan and the Viceregal party, at the town hall by Mr. E. Hodgson, chairman of the Rathmines Urban Council; Mr. R. Danne Bolton, chairman of the Electric Lighting Committee; the members of the committee; and Mr. F. P. Fawcett, clerk of the Council Subsequent to the formal inauguration of the supply and the involved speechmaking, the Viceregal party was conducted round the electricity works by the chairman of the Council and the members of the Electric Lighting Committee, including Messrs. R. D. Bolton (chairman), R. Booth, J.P., F. A. Butler, C.E., C. W. Hely, J.P., T. Hewson, E. Hodgson, L. C. Murphy, J. P. Pile, and Thomas Edmundson. The consulting engineer, Mr. Robert Hammond, explained the working of the generating plant and other electrical apparatus.

SOME NEW MOTOR-STARTING SWITCHES.

We were invited recently by the Electrical Transmission Company, Limited, of Albert Works, Hammersmith, to a private inspection of two new motor-starting switches which the firm are about to place on the market. A brief description of these switches may interest our readers. What may be termed the "B" type switch possesses several special features, the essentially novel of which is perhaps that the handle is not directly attached to the switch arm, but is only held to it by electromagnetic means when the conditions are suitable. The switch arm and handle lever are of iron, and have pole-pieces attached to them extending across the face of a coil mounted to surround the iron spindle of the switch, and together they constitute an electro-magnetic clutch. The switch also has a temporary contact (shown just above the clutch coil in the illustration, Fig. 1), a "non-sparking" arrangement (shown at the bottom left in the illustration), and a maximum cut-out and hand switching-off handle (shown at the bottom right in the illustration).

Fig. 1 shows the switch in the "off" position. The action of switching on is as follows: The handle is brought towards the switch arm, so as to bring the pole-pieces together, and in doing so makes the circuit at the temporary

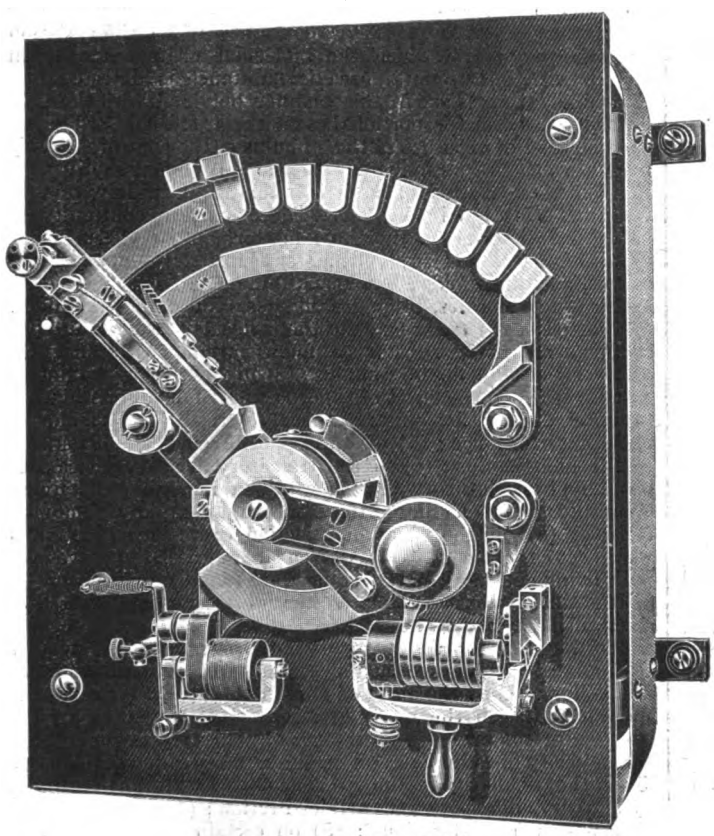

FIG. 1.—"B" Type Switch.

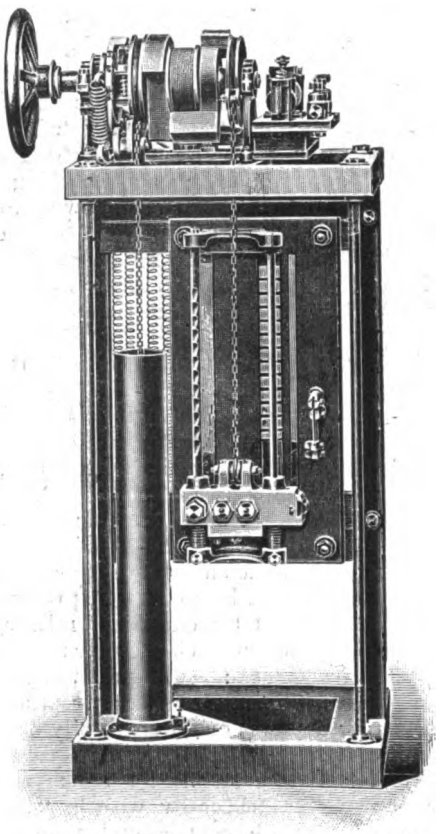

FIG. 2.—"A" Type Switch (on special frame).

contact to energise the clutch coil and also excite the motor magnets, as the clutch coil is in series with the motor field-magnet coils. It is then necessary to pause for a short period, depending on the size of the motor, until the current in the field magnets has risen to about its proper amount, as otherwise the clutch will not be sufficiently powerful for the switch handle to draw the switch arm against the spring which has brought it to the "off" position. The switch arm may then be drawn slowly from contact to contact until the full "on" position is reached, when the switch handle is held by a spring detent. The gradual rise of the current in the field magnets of a motor, especially those of large size, can be easily noted by placing an ammeter in the circuit, and where it is not taken into account serious excessive flushing of current with damage to the switch contacts and sparking at the motor brushes results, through the only partial excitation of the magnets. Should the operator switch on too fast the maximum cut-out acts, short-circuiting the coil, so releasing the switch arm from the handle, when it springs back to the "off" position, inserting the resistance as it does so. The object of the "non-sparking" arrangement is to temporarily close the circuit whilst the switch arm is travelling to the first contact of the switch, when it is cut out of circuit.

Digitized by Google

Open-type switches are provided in all cases with wire guards so that the action of the apparatus cannot be interfered with, and the maximum cut-out handles are arranged so that they cannot be held down. The other special features claimed for the "B" type switch may be summed up as follows: it cannot be switched on until the motor field magnets are well excited, or without a suitable difference of potential; it automatically switches off if the operator attempts to switch on too quickly; it automatically switches off if the current exceeds a given amount; it automatically switches off if the current supply fails; it always inserts the resistance before breaking the circuit; it breaks the circuit on carbon-sparking contacts; and all contact parts are interchangeable and easily renewable.

In general principle the "A" type switch is the same as the switch just described, but the arrangement of the parts is different, as the contacts are arranged vertically in alignment, and the clutch and other apparatus is fixed at the top of the pedestal. The great advantage of this switch over the "B" type is that it takes the starting-up entirely out of the operator's control, and switches on at the speed for which it is adjusted. The operator is unable to interfere with the process of switching on, although at any time he can instantly switch off. It also avoids a fault which has prevented the satisfactory continuous working of other slow-moving switches, in that the switch arm stops when fully on each contact and proceeds with a "quick-make" to the next, when progressively cutting out the resistance. This prevents the fusing and sparking which takes place with a slow-moving switch arm, owing to the great current density when passing from one contact to the next, as practically the whole current passes through the contact in advance, and with a slow moving switch the actual contact area for a considerable time may amount to little over a line or a point.

The action of the switch (Fig. 2) is as follows: When starting up the operator winds up a heavy weight in a dash-pot, by means of a spring bolt. When fully wound up the hand-wheel shears out of engagement with the weight by compressing the spring bolt, and is locked to prevent further forward movement. The weight then descends in the dash-pot, drawing the switch arm over the contacts, and the "step-by-step" motion is secured by a spring detent, which acts at each contact. The action of moving the hand-wheel backwards to switch off causes the short-circuiting of the clutch and release of the switch-arm. Of the special features claimed for this switch the following may be mentioned: it is practically impossible for the most unskilled operator to damage either the motor or the switch; it switches on automatically at a slow speed, which is out of the operator's control; it switches on automatically after the motor field magnets are well excited; it switches on automatically with a "step-by-step" action, stopping on each contact and then proceeding with a "quick make" to the next; it switches off automatically if motor is overloaded or the current exceeds a given amount; it switches off automatically if the current supply fails; it always inserts the resistance before breaking the circuit; it breaks the circuit on carbon sparking contacts; it cannot be operated if there is no current supply, or without a suitable difference of potential; the rotation of the hand-wheel "clockwise" switches on, whilst a small movement in the reverse direction switches off; there is nothing outside the case but the operating handwheel (the whole of the mechanism is enclosed in a strong weather-tight case, the side doors of which are bolted from the inside of the top cover; the padlock on the top cover, therefore, locks up the entire case); and all contact parts are easily renewable.

With both of the above-described switches the name of Mr. Walter F. Jones, manager for the Electrical Transmission Company, Limited, must be associated as inventor. We understand that a large sum of money and a great deal of labour have been expended in perfecting the gear, but if extended experience with the switches proves the objects aimed at to have been satisfactorily attained, this expense and labour will have been amply rewarded. It only remains to add that repeated operations of the switches under normal conditions in our presence were entirely satisfactory.

ON THE SIMILARITY OF EFFECT OF ELECTRICAL STIMULUS ON INORGANIC AND LIVING SUBSTANCES.*

BY JAGADIS CHUNDER BOSE, M.A., D SC, PROFESSOR OF PHYSICAL SCIENCE, PRESIDENCY COLLEGE, CALCUTTA.

If we take a piece of living tissue, say a piece of muscle, and subject it to an electric stimulus, there will be produced a contraction; the stimulus causes a molecular rearrangement by which the form of muscle is changed. On the cessation of stimulus the muscle, recovering from the molecular strain, gradually attains its original shape. The effect of stimulus on nerves is, however, not apparent; there is no change of form. The molecular disturbance due to stimulus can, nevertheless, be detected in an indirect manner from certain electromotive variations that are produced. If, now, a mass of metallic filings be taken and subjected to electric shocks there is no visible change. The substance appears to be irresponsive or dead to stimulus. Are inorganic substances, then, really irresponsive? Could this apparent want of response not be due, after all, to our inability to detect the profound molecular changes that may have nevertheless taken place in the substance under the action of stimulus? In nerves it is seen that the molecular changes can only be detected indirectly by an electric method. The author describes an electric method based on the variation of conductivity, by which the molecular change due to an electric stimulus in an inorganic substance is detected and measured. Curves are in this manner obtained with the conductivity variation (proportional to molecular effect) as ordinates, and the time of exposure to the stimulus or the time of recovery from the effect of stimulus as abscissæ. It is next shown that the effect on matter of electric stimulus of widely varying frequencies is a continuous one. There is also a continuity of effect on all forms of inorganic matter, similar effects being produced not only (1) in all elementary substances—metals, non-metals, and metalloids; but also (2) in metallic compounds—such as the chlorides, bromides, iodides, oxides, and sulphides.

Comparisons are next made of the molecular response in both inorganic and living substances under varying conditions: (1) on the effect of moderate stimulus; (2) on the effect of maximum stimulus; (3) on the effect of superposition of medium stimuli—(*a*) effect due to slow intermittence, (*b*) tetanic effect due to rapid intermittence; (4) on the opposite effect due to strong and feeble stimulus; (5) on the transitory negative effect; (6) on the physical theory of "fatigue" in inorganic and living substances; (7) on the various means of rapidly removing fatigue; (8) on the effect of injection of various substances which act as "poisons." In all the above cases the curves for both living and inorganic substances are found to be similar.

The author next explains a theory of vision, and describes an artificial retina; the various effects of radiation on this artificial retina explain many obscure phenomena of vision. Parallel experiments are then described with the artificial and real retina: (1) on the effect of short exposure to the action of radiation; (2) on the effect of intermittent radiation, on the question of the presence or absence of "flicker" depending on the intensity of radiation, and on the rapidity of intermittence; (3) on the peculiarity of the visual sensation curve, as explained by the curve of effect on the artificial retina; (4) on the different elements of retinal fatigue; (5) on certain curious reversal effects; (6) on after-oscillation and visual recurrence; (7) on the novel phenomenon of binocular alternation of vision, and on the analysis of superposed images by alternate after-vision; (8) on the persistence of retinal oscillation, and its continuity with the phenomenon of memory.

In all the phenomena described above there is seen an identity of effect of external stimulus on both living and non-living forms of matter. It is difficult to draw a line and say "here the physical process ends and the physiological process begins," or "these are the lines of demarcation that separate the physical, the physiological, and the beginning of psychical processes." No such arbitrary lines can be drawn, there being no breach of continuity.

The Hospital Scandal.—The reports received by Lord Roberts as to the treatment of the British prisoners in South Africa, and more particularly the sick and wounded, reflect very unfavourably on the Red Cross staff with the Boers. There are, however, a few names which stand out very clearly as men who did their duty well, in deep contrast with others, who were unwilling to risk trouble with the Boer Government by doing so. The report of Colonel Hunt to Lord Roberts with reference to the Pretoria hospitals gives the names of two or three of these men, amongst whom we are pleased to find an electrical engineer, Mr. Wolley Dod. This gentleman was one of a committee of three, formed in the town, who ably assisted Dr. Von Gernet. To this doctor the greatest praise is given, as also to the committee who helped him.

* Abstract of paper read before the British Association at Bradford.

THE EVOLUTION OF SWITCH GEARS FOR HIGH-PRESSURE ALTERNATING CURRENTS.

BY W. E. WARRILOW.

(Continued from page 310.)

THE ELECTRIC CONSTRUCTION COMPANY.

The manufactures of this firm in connection with switchboards for high-pressure continuous current are well known, but they have, however, erected boards for alternating-current stations also. They resemble the preceding boards in respect to connections and passage at the back. Fig. 31 is a photograph of a board supplied to the Morley Corporation for their alternating-current station. It consists of alternator and circuit panels arranged for a single-pole system, the outer being earthed. The alternator panel is fitted with switches, fuses, and instruments for three alternators, each machine being provided with an ammeter, two single-pole switches, and fuse. The two switches, which are of the plug type, are provided to enable the machine to be connected to one of two 'bus bars. The fuse is drawn through a glass tube fixed in a porcelain case, and fitted with suitable contacts. The machine switches are provided with guides, so that the switch may be fixed in readiness for driving in after synchronising. The circuit panel is exactly similar to the alternator panel, with the exception that the switches are not provided with guides.

The dynamo and circuit panels are placed on either side of a synchronising panel, fitted with Cardew voltmeter, synchronising lamps, three low-tension voltmeters (one for each bar and one for incoming machine), eight synchronising plugs, and an interconnecting switch for coupling the bars together. Five small transformers are provided for synchronising and for the voltmeters. Fig. 32 is a drawing of this high-tension board, which will make clear what is not seen in the photograph. A regulating table is placed in front of the main board, from which the exciter currents are controlled. Fig. 33 shows this table with its regulating and field-breaking switches and ammeters. In the photograph of the high-tension board the table may be seen, and the cables leading from the stops on

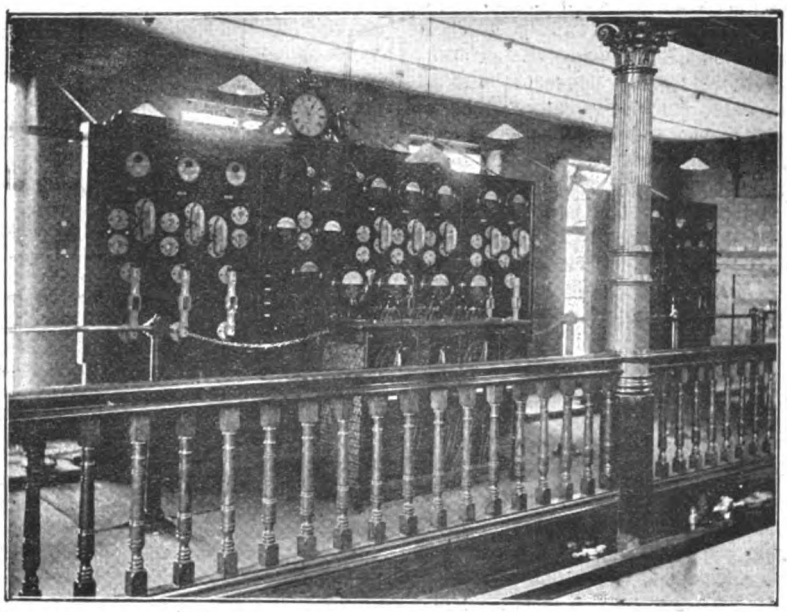

FIG. 31.—Morley Switchboard.

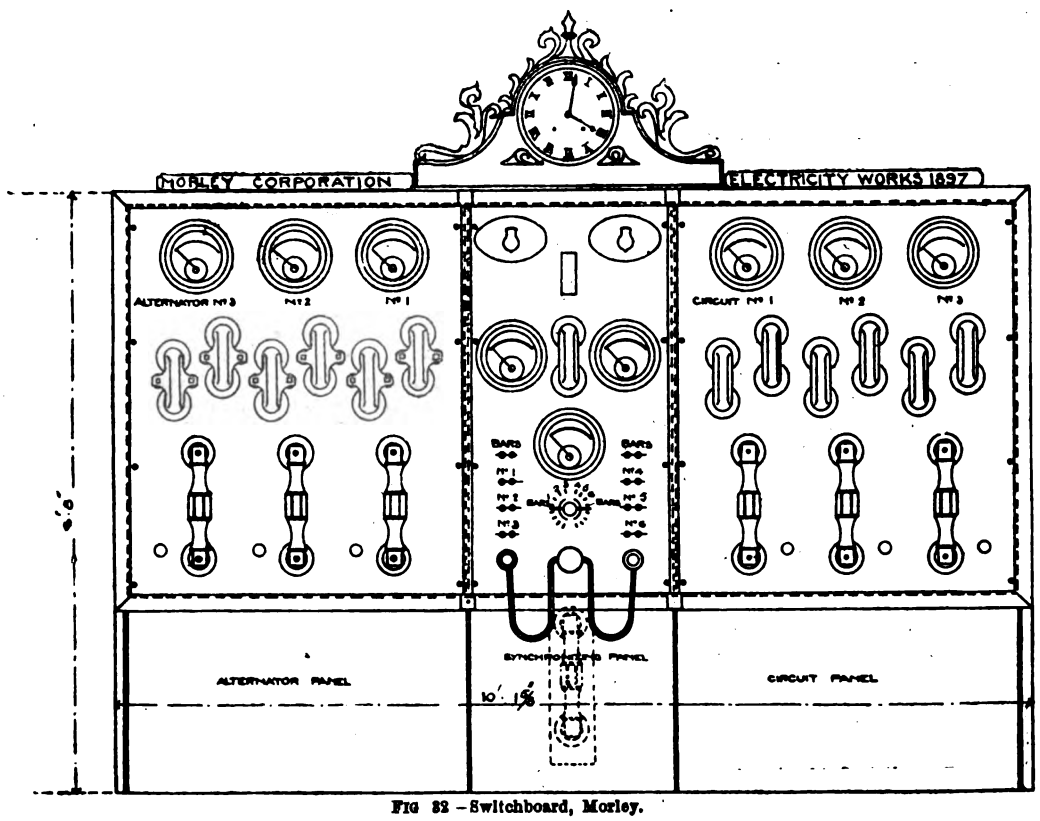

FIG 32.—Switchboard, Morley.

Digitized by Google

the regulating switches to the resistance frames are also very evident.

Fig. 34 is a photograph of a board of older construction, it having been made some eight years ago for Johannesburg. At first sight it resembles a continuous-current board, and might be mistaken for such. In the distance is the alternator board, fitted with field breaking and regulating switches at the bottom and high-tension fittings above. Cardew engine-room voltmeters are fixed above this board In the middle distance is the synchronising board, fitted with double-pole switches for paralleling and synchronising plugs and lamps. In the foreground are the circuit panels, four in number, fitted up with main switch, ammeter, plugging arrangement for coupling the circuit to any

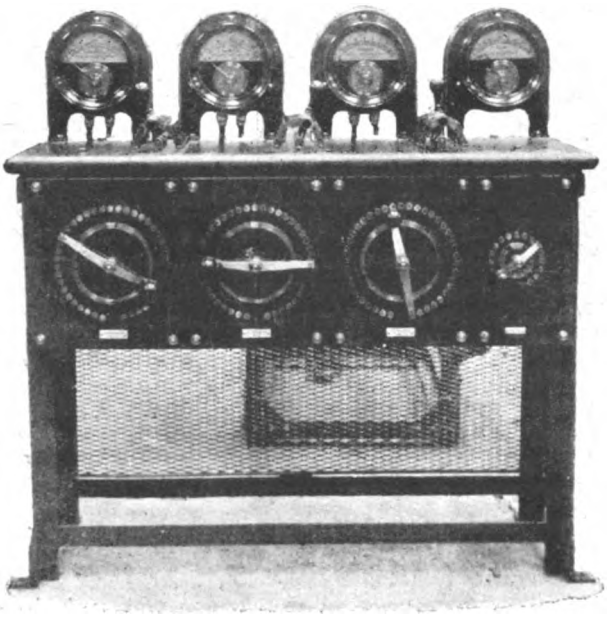

FIG. 33.—Regulating Table, Morley.

machine, and a throw-over switch, by means of which any machine may be taken off the circuit and another one inserted. It will be noticed that ample room for extension is provided in both dynamo and circuit panels. It must be noted that the above boards were made to engineers' specifications, and since first erection have been considerably extended.

COWAN STILL.

The switchboard to be now described differs from those previously illustrated in that it has no passage at the back, and it cannot be handled at the back except in a "dead"

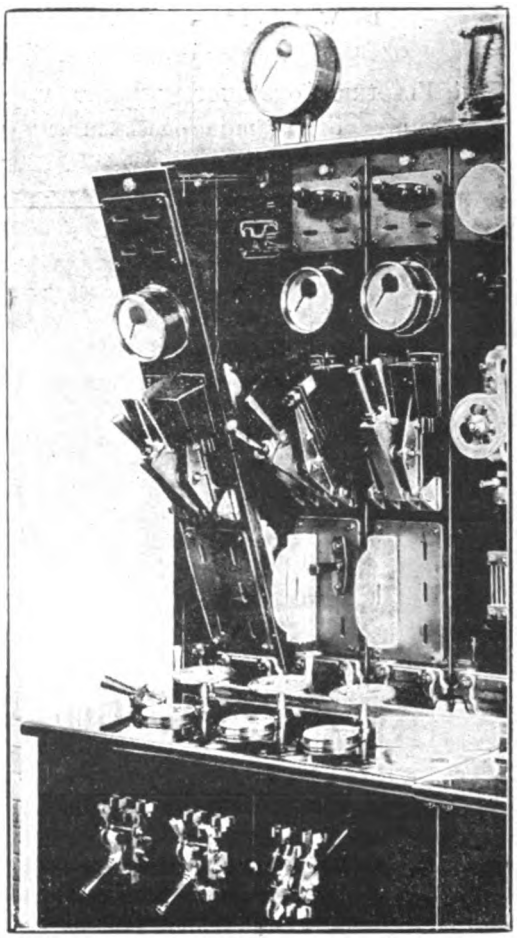

FIG. 35.—Cowan Panels.

state. This desirable result is obtained by making the board up of narrow slate panels which can be hinged forward on their lower edges, so that the back of the slate becomes accessible. The photograph (Fig. 35) shows a portion of a board so constructed, where it will be seen that each panel is fitted with two 'bus-bar plugs, ammeter, switch, and duplicate fuse contacts. Below the high-tension board is the regulating table with rheostat, hand-wheel, ammeter, and field-breaking switch, arranged verti-

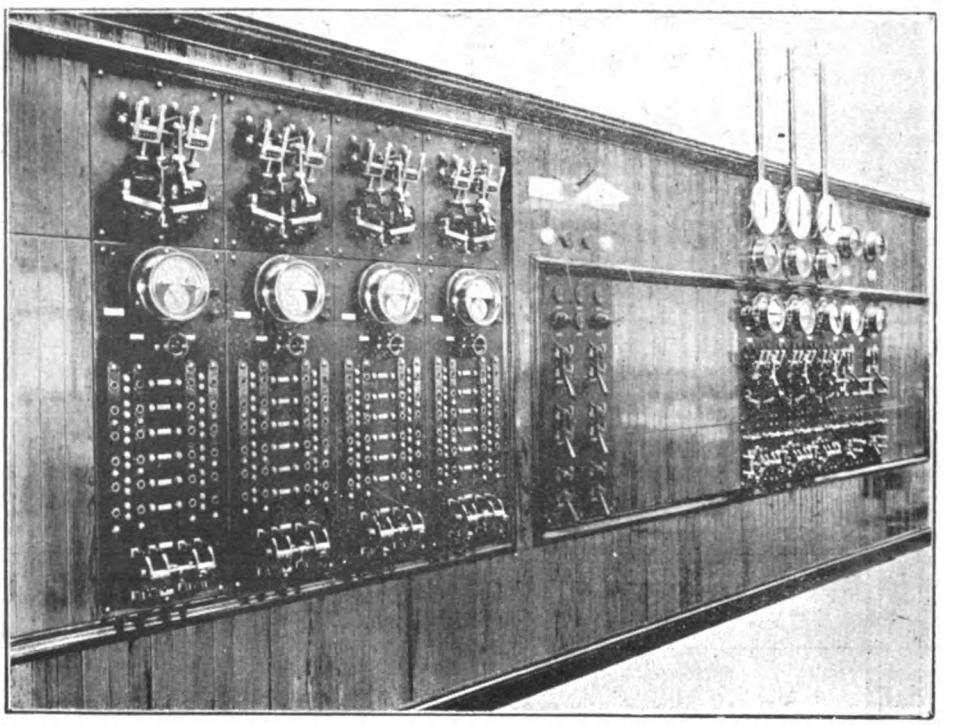

FIG 34.—Johannesburg Switchboard.

Digitized by Google

cally under the dynamo panel they are intended to control. By this means high and low tension portions of the board are kept in perfect symmetry. By withdrawing the 'bus-bar plug and high-tension fuse the panel may be hinged forward as shown in the photograph, and any alterations required can be carried out with safety, as the removal of these fittings from the circuit entirely isolates the panel.

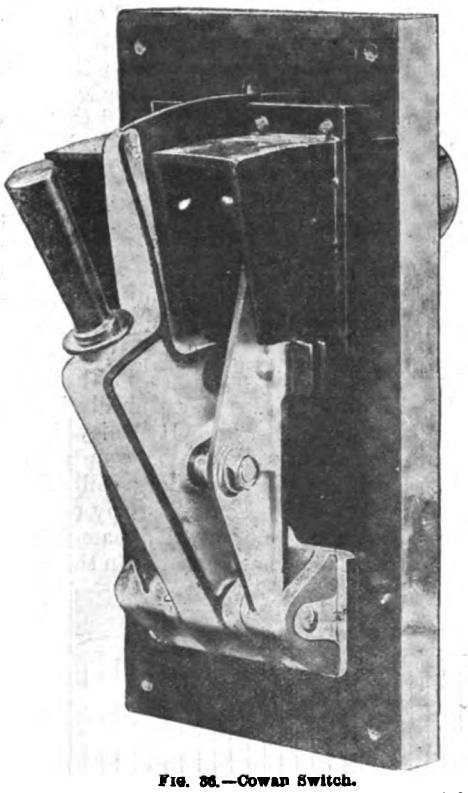

FIG. 36.—Cowan Switch.

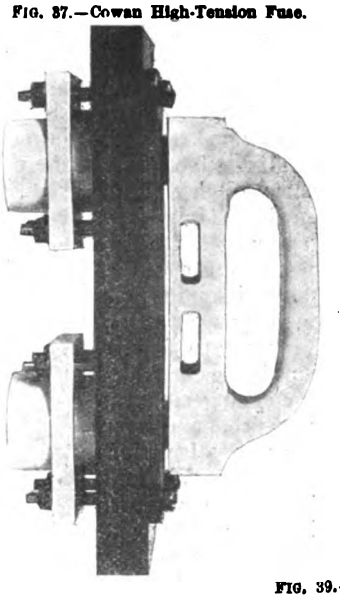

FIG. 38.—Ordinary Switch, Opening Field Circuit.

FIG. 39.—Patent Switch, Opening same Circuit as above.

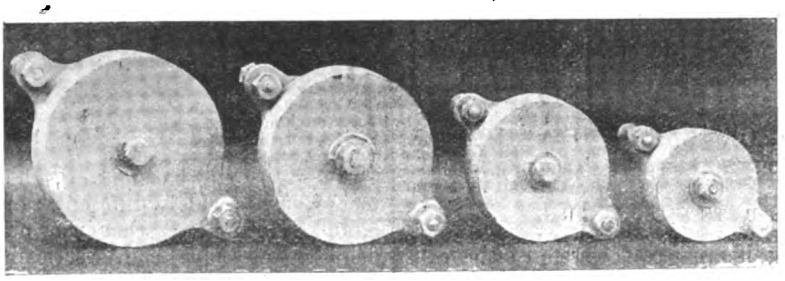

FIG. 40.—Cowan Fireproof Iron-clad Resistance Units.

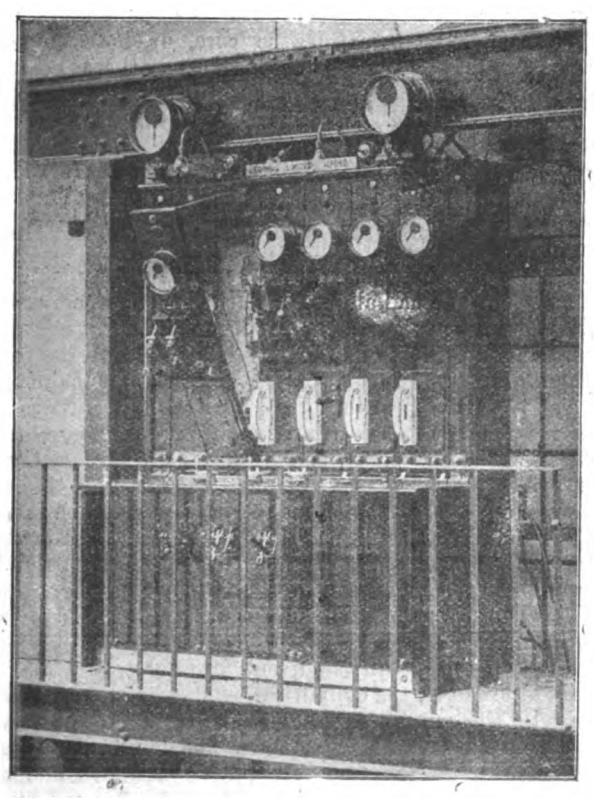

FIG. 41.—Small High-Tension Board at Watford.

Fig. 36 is a photograph of the high-tension switch, which is of the double-break type. An insulating shutter is fixed between the two blades and attached to the handle.

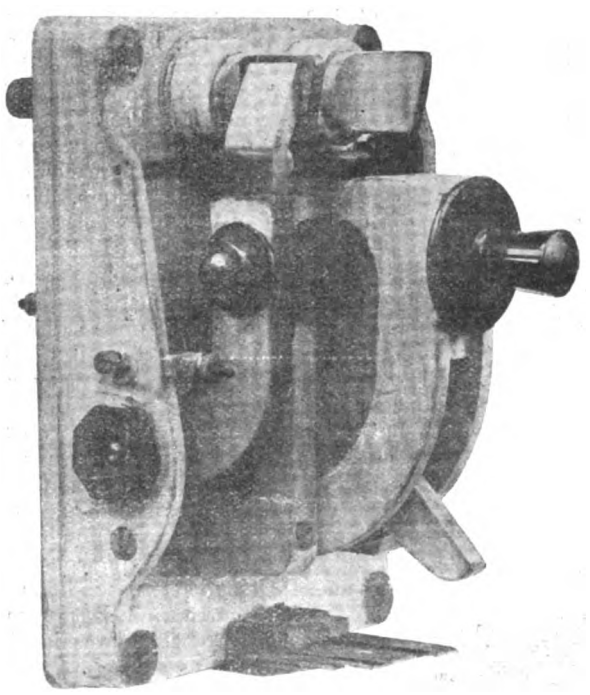

FIG. 42.—Andrew's Discriminating Cut-out. Low Tension for Sub-Stations.

A switch of this pattern will safely open circuits of 500 amperes capacity, and all high-tension parts are most care-

Digitized by Google

fully shielded. The high-pressure fuse is illustrated by Fig. 37. It is of the switch-fuse type, and only differs from other examples in the arrangement of the fuse wire. This passes from one terminal in the handle to the other through a chamber formed of asbestos pieces laid side by side, retained in position by mica strips. Duplicate fuse contacts are provided in the panel to allow a faulty fuse to be replaced without interrupting the circuit. In the figure a small plug will be seen inserted to the right of one of the fuses. This is the synchronising plug, and it may be inserted to couple the synchroniser to the incoming machine. The alternators may be connected to one of two 'bus bars by means of a plug inserted at the top of the board above the ammeter. The field switch, mounted on the front slates of the regulating desk, is arranged to short-circuit the field on itself through a non-inductive resistance. Fig. 38 is a photo of an ordinary switch opening the field when the arc produced can be plainly seen, while Fig. 39 is a photo of Cowan's patent switch opening the same circuit. The two small white points at the contact jaws represent the arc, which is, of course, inappreciable. The resistance units are constructed on a new principle, there being no connecting wires leading away to frames, etc. Each unit is encased in iron, the stops being embedded in a fire-resisting composition. The whole arrangement can be raised to a very high temperature without danger. Fig. 40 is a photograph illustrating four units of various sizes. Fig. 41 is a small Cowan board erected at Watford. This firm are the makers of Andrews's patent non-return cut-outs for use with alternators running in parallel, and Fig. 42 illustrates a discriminating form for use on low-tension circuits in sub-stations. When dealing with heavy currents Messrs. Cowan's make use of a switch of the water-break type placed above, and operated from, the switchboard platform by means of levers.

THE CONSTRUCTION OF LARGE DYNAMOS AS EXEMPLIFIED AT THE PARIS EXHIBITION.*

BY SILVANUS P. THOMPSON, F.R.S.

The author, in opening his paper, referred to the continual changes which are taking place in the design of electrical apparatus, and of the way in which practices which seemed to be quite standardised are gradually discarded in different countries. He was, therefore, very keen when visiting the Paris Exhibition to see what progress had been made by the various nations in dynamo design. The Exhibition afforded exceptional advantages in this respect, on account of the large alternators and direct-current dynamos which were exhibited by electrical engineers from every country manufacturing such machines. As an instance of the way in which types appear and afterwards die out in different countries, Prof. Thompson referred to the two-pole type of direct-current dynamo so largely used in England. This class of machine was not exhibited, except for very small motors, by any Continental firm. Another English type which was not represented by foreign exhibitors at the Paris Exhibition was the alternator with the armature built up of thin coils of bare copper, such as is manufactured by Mr. Ferranti. To begin with the alternators exhibited at the Paris Exhibition, the author characterised them as getting more "flywheel" in style—that was, they were increasing in diameter and decreasing in length. The alternators might be divided into four types. The first of these had external magnets which were fixed, and a revolving armature inside the same. The second type contained those machines which had a stationary armature surrounding an internal system of magnet poles built up on a flywheel. The third type had no revolving conductors in either armature or field. It included what is known as the inductor alternator. The fourth and last type of alternator had a stationary armature which was inside a revolving magnet, and in order that this might be arranged the field-magnet system had to overhang at one side of the flywheel. With respect to the number of machines of each type which were exhibited, there were rather few of the first type and a great many of the second type. Of the third or inductor type there were hardly any exhibited, which was somewhat surprising in view of the great attention which had been paid to inductor alternators in the past. There were three machines of the fourth type on view, in which he was much interested. He believed that this class of machines was first used by Mr. C. E. L. Brown, who employed the type when making the Cairo alternators. The advantage of the machine was a mechanical one. With the poles fixed on the inside of the extended rim of the flywheel, the centrifugal force of the revolving mass of each pole tended to keep it in place against the rim. It also counteracted the magnetic pull which was inwards. In the more usual type of alternator field with the poles projecting outwards from the flywheel, both the centrifugal force and the magnetic pull were in the same direction, and had to be provided for mechanically in the means of attaching the poles to the rim. He believed that Mr. Ferranti was the first to introduce bare copper strip wound in an edgewise spiral for the exciting coil of the field magnets. This method was now very largely used by practically all the large manufacturers of dynamos, and large sections of copper tape were now wound up in this way.

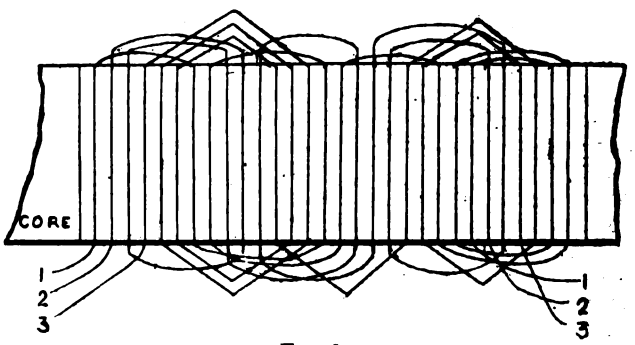

FIG. 1.

As was somewhat natural, the voltages of the various machines was widely different, ranging from 2,000 volts to 5,000. He noticed that the practice of laminating the field-magnet cores had practically disappeared as far as continental makers were concerned. They used instead a cast-steel core with a laminated pole tip. Amongst the large armatures there was not one of the surface-wound type, but in every case the conductors were either wound in holes in the core, or between teeth formed in the same. For insulating these holes or teeth, mica or micanite was almost universally employed. It was interesting to compare in this respect the machine of the present day manufactured by continental makers with those exhibited at the Frankfort Exhibition in 1891. The machines at that date almost all employed what might be described as the paper type of insulation, and screwed connections between the armature conductors and the commutators. English manufacturers even at that date had all adopted the sweated connection. This year showed that the screwed connection at the commutator had practically disappeared, as had also the paper type of insulation, except where it was used for making up space. He had looked into the question of the number of slots per pole, or, to put it more accurately, the number of slots per pole per phase, employed by the various Continental makers. In the case of one large machine, this was as low as one slot per pole, but the greater number had at least two slots per pole per phase. In the largest alternator which was exhibited by the Allegemeine Elektricitäts Gesellschaft, of Berlin, five slots per pole per phase were used. There was one machine which, curiously, had 2½ slots per pole.

In the winding of direct-current armatures, and also in certain alternators, the cylindrical winding was very largely used. In this winding there were at least two conductors in each slot, one above the other. The lower conductors were bent round the armature in one direction and the upper conductors in another, but they were always kept at the same distance from the axis, so as to form ultimately a cylinder. On a machine exhibited by Ganz and Co., he had discovered a most unsymmetrical system of winding. It

* Abstract of paper read before the British Association at Bradford.

Digitized by Google

was a three-phase machine, and the three circuits were arranged as shown Fig. 1. It will be seen that circuit No. 1, for instance, passes from the first slot to the sixth; it then skips seven slots, and, turning round, embraces six slots instead of five; with the next turn it embraces five, and the last turn six again. If the third circuit is looked at it will be seen that the first complete turn embraces no less than nine slots. The reason for this great irregularity is that it enables certain sections of the armature core, equal to four poles, to be wound in the shops, while only single connections have to be made to each circuit when erecting the various sections in the station. It will be seen from the diagram that the section diagrammatically represented is complete in itself.

The Helios company showed machines which would give either single-phase or three-phase currents at will, but Prof. Thompson had not time to describe in detail the winding employed. With the increase in diameter of the alternators, due to increased output, the mechanical stability of the large rings was of importance. It was interesting to note the different ways in which different makers obtained the necessary strength. In one case he noticed that the cast-iron frame was made about one yard wide, whereas the length of the core was only 10in. In an alternator exhibited by the Schuckert Company the required stiffness was obtained by a number of stay-rods in tension, which were secured to a ring concentric to the shaft and of comparatively small diameter.

The question which in France seemed to be largely engaging the attention of dynamo designers, was the compounding of alternators. There were two methods of doing this exhibited, the first of these was the Hutin-Leblanc system, which has already been described in our columns.* Prof. Thomson proceeded to describe another system, which depended on the principle that an induction motor with its rotor driven slightly above synchronous speed becomes a generator. These compound exciters for generators were designed to compensate not only for changes in load, but also for changes in the power factor of that load.

The Russian branch of Messrs. Siemens and Halske exibited a direct-current dynamo, in which the tendency to spark was kept down by the following means: the inner surfaces of the poles did not form a cylindrical surface concentric with that of the armature. Instead of this the width of air-gap was increased, being smallest at the edge of the pole which the armature conductors approached, and largest at the edge from which the conductors receded. In the case in point the increase was from 7mm. to 9mm. Another new type of direct-current dynamo was exhibited by Messrs. Ganz and Co., in which unusually large teeth were formed in the armature. They were in fact only six teeth to a pole. The poles had extended pole-pieces of peculiar shape, and were built up of laminated steel. The whole of the plates, however, did not have the polar extensions on them, so that the horns had a small cross-section of iron.

It was, of course, impossible to obtain accurate test figures for all the machines without carrying out a series of experiments, which would take a long time. He had tested some of the machines by the Steinmetz formula, in which d equals the diameter of the revolving part and l equals the length of core. Steinmetz found then that the expression $\frac{d\,l}{K\,W}$ gave a numeric varying from six in bad designs down to, say, three in good designs. With an increase in size, however, the numeric was decreased, so that for a 1,000 h.p. he had found the figure as low as $1\frac{1}{2}$.

Discussion.

Mr. Alex. Siemens, in opening the discussion, explained that the reason why their dynamo at the Paris Exhibition was not at work more frequently was that the circulating pump could not always provide the necessary water for condensing. The pump had been placed too high by a draughtsman who wished to give the pump due prominence. Other engines used the same circulating water, which hence got somewhat aerated. The result was that the pump in question would not always lift the water from the main.

Mr. J. Sheolbred remarked that the relative advantages between the two-pole and multipolar type of dynamo was largely a question of £ s. d. He would express his opinion, however, that up to the present he had not been able to find a multipolar dynamo to give as good results as the two-pole type did for sizes up to 200 kw.

Prof. S. P. Thompson suitably replied.

* *Electrical Engineer*, vol. xxvi., p. 56.

RECENT TRAMWAY CONSTRUCTION, WITH SPECIAL REFERENCE TO THE DEMERBE SYSTEM.*

BY WILLIAM DAWSON.

It is about 35 years since the introduction of tramways into the large towns of Europe, and an account of the changes and developments which have been made in this means of transport would be very interesting from an historical point of view, but of little technical or industrial interest. The principles of construction, the different systems formerly in use, and the mode of traction have all been revolutionised in the comparatively short time which has passed since the introduction of tramways into this country, so that there is little to learn from the past. It would take up too much time to enumerate and investigate all the systems of tramway construction which were successively tried when tramways were generally worked by horse traction, and which have now given place to other methods more suitable for mechanical or electric traction. The first tramrails were laid on either longitudinal or transverse wooden sleepers, but it was found that the wood soon rotted. The sleepers were therefore discarded, and experiments made with tramways constructed entirely of metal. The Vignoles rail was adapted for this purpose, and, finally, rails of the Brocca (or girder) and the Demerbe (or trough) type were manufactured.

The Brocca rail was afterwards adopted in Germany and England under the name of the Phœnix or Girder rail. This form of rail was a modification of the Vignoles rail, as the foot or bottom flange was merely widened and laid direct on the soil or on a bed of concrete. It is now generally adopted throughout England, but in my opinion has not proved a success. When animal traction only was used, very little attention was given to the fishing of the joints of the rails, but on the introduction of steam and electric traction it was soon found that the joints were unable to stand the increased strain. The fishplates were increased in length and thickness until in some cases they were 3ft. long and 1in. thick; eight 1in. fishbolts were used, sole-plates were placed under the ends of the rails, narrow steel strips were placed on the top of the bottom flanges of the rails at the joints, and the whole securely bolted together with six $\frac{3}{4}$in. bolts. The joints still worked loose, and it is now recognised that all it is possible to do in this direction is insufficient to make a perfect joint. In Germany, the ends of the rails were cut obliquely, afterwards they were halved on to each other, or the ends were notched, and a fishplate placed in the recess. All possible methods have been tried to prevent the joints working loose, and numerous patents have been obtained for different ways of strengthening the fishing—all costly, and not completely satisfactory in spite of the extra outlay. The girder rail joint is undoubtedly defective, and the trouble which arises is to be attributed partly to the fact that the top and bottom of the fishplates corrode, as also does the under side of the head of the rail. The fishplates then occupy a less space, and are less in depth than they were when new. The head and bottom flange of the rail is not firmly gripped by the fishplates, and as their proper work is to maintain the level of the ends of the rails under the action of unequally distributed forces, the joint soon becomes loose. It is not, therefore, surprising that the consideration of the best means of fishing the joints of tramways has brought to the surface numerous, complicated, and often very remarkable methods of dealing with this branch of tramway construction.

The Demerbe system of tramway differs entirely from all other types, and possesses in many ways some of the chief attributes of a perfect tramway. It consists of a hollow trough rail (A, Fig. 1), and the fishplate (B, Fig. 1) is placed inside under the ends of the rails, and exactly fits

* Paper read before the British Association at Bradford.

Digitized by Google

its contour, the point of application being immediately under the head of the rail. When this system was first introduced the fishplate was pressed into the rail by means of bolts, but it was soon found that this was not satisfactory, and cotters (E, Fig. 1) were used. As the holes in the fishplates and rails are cut at different depths, when the cotters are driven in the fishplate is forced close up to the underside of the rail. The ends of the cotters are then clinched against the side of the rail, and are thus fixed and prevented by any possibility from working loose. The rail (D, Fig. 3), a little smaller than the opening it has to fit, is inserted and driven up. This arrangement of the tie bar enables the rails to be fixed to gauge with almost mathematical exactitude.

In England, as a rule, a concrete foundation is laid the whole width of the carriageway to receive the paving, and when the Demerbe rail is filled with concrete in the manner above described it becomes attached to the concrete foundation, and is practically part and parcel of the carriageway. It is, therefore, capable not only of withstanding the strains

FIG. 1. SECTION OF THE RAIL WITH FISHPLATE

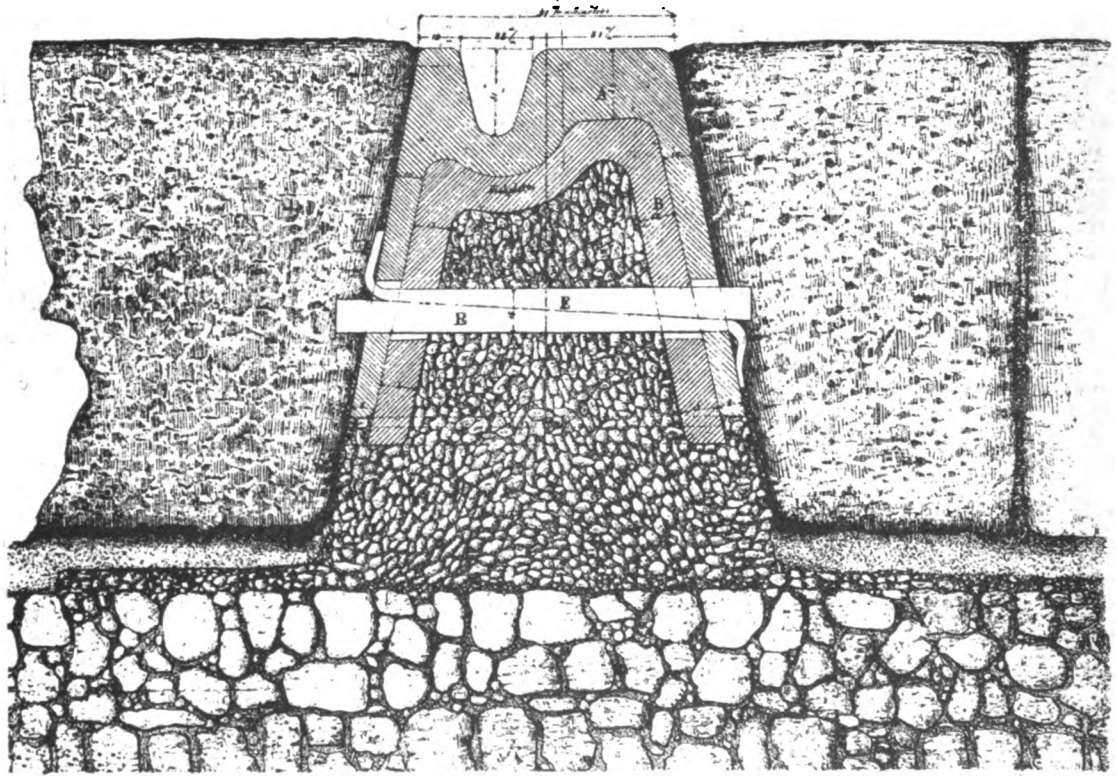

FIG 2 TRANSVERSE SECTION OF THE LINE PAVED

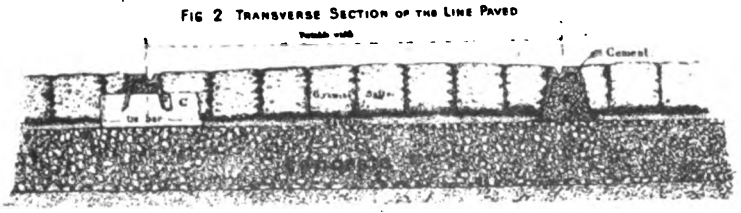

FIG 3. CONNECTION OF RAIL WITH TIE BAR

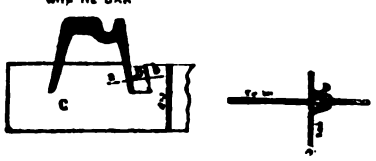

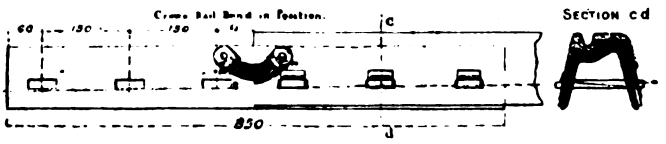

FIG. 5 SECTION c d

FIG. 4 ELEVATION OF FISHPLATE AND JOINT

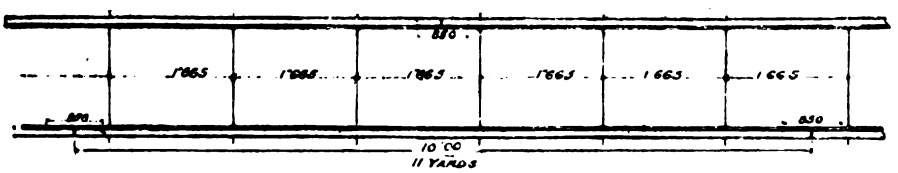

FIG. 6 PLAN OF THE LINE

when laid in position in the carriageway is completely filled, by means of specially designed tools, with concrete, composed of four parts of ½in. unscreened granite shingle to one part of Portland cement. The tie bars (G, Figs. 2 and 3) used in the Demerbe system are flat, and the use of screw ends, nuts, and bolts is avoided. The rail is inserted into two oblique grooves, one of which is cut so as to exactly fit the outer side of the rail, whilst the other is wider, so as to facilitate the introduction of the inner side of the rail. In the space which is left a wedge of soft steel caused by the cars, but also all the strains and vibrations caused by the ordinary vehicular traffic, without any loosening of the joints or displacement of the paving. The girder rail is laid direct on the concrete foundation, and the oblique strains brought to bear on the head of the rail by the tramcars and other traffic causes the extremities of the foot or bottom flange of the rail to have a tendency to crush the concrete, and so allows the rail to oscillate on its base. As soon as the rail is subjected to the least movement or vibration, a narrow fissure is produced along-

Digitized by Google

side, which increases in width as the foot becomes more moveable. Water penetrates between the paving and the rail, and in frosty weather the paving is uplifted. The joint of the rails is also partly responsible for these defects, as the water finds an early passage between the rails and fishplates.

It is necessary to take into account another factor which contributes to the grinding away or pulverisation of the concrete. The ends of the rails rest on a sole plate, which is intended to maintain the ends of the rails at one level. When the cars pass over the track the shock is harder at the joint than on the rest of the rail, where the movement caused by the car is more elastic, because the sole-plate and the concrete do not support the rail with the same rigidity, and the rails become dented at the joints even when they are in perfect allignment. It follows then that the same rigidity should exist at the middle of the rail as at the joint. In the Demerbe system this is so, as the concrete becomes perfectly attached to the rail, and the ridge of armoured concrete becomes part and parcel of the foundation itself. The same resistance is offered to the weight of vehicles for the whole length of the rail, no part being found to be weaker or more elastic than another.

In 1894 a short experimental length of the Demerbe rail was laid in Leeds-road, Bradford, end to end with a similar length of girder rail. Both portions have been subjected to a five minutes' service of steam locomotive cars since that time. About three weeks ago a Demerbe rail was removed, in the presence of the Tramway Committee, to ascertain its condition. The rail, joint, and gauge were found to be in every way perfect, and it was only after repeated blows with heavy hammers that the rail could be detached from the concrete foundation, and when raised it dragged up with it part of the foundation. No money whatever has been spent in repairing this portion of Demerbe tramway, but the adjoining portion of girder rail has been several times repaired during the six years it has been laid down. The setts used alongside the Demerbe rail are splayed to fit the sides of the rail, and laid directly against it, the rail thus serving as a support for the paving; and there is no tendency either for the setts to rise or fall as is the case with the girder rail. There are in Bradford 40½ miles of tramways, of which 36½ miles are laid on the girder system, with rails weighing 105lb. per yard, and fishplates weighing 80lb. per pair. There are four miles of Demerbe tramway, constructed of rails weighing 70½lb. per yard, and fishplates weighing 51½lb. each, and the Corporation have further in course of construction an additional 10½ miles of tramway, which they are putting down on the Demerbe system.

The detailed cost per yard of single track on the two systems, based on the price of materials delivered at Bradford, is as follows:

Demerbe System.	s.	d.
Rails	10	7·9
Fishplates	0	9·4
Tiebars	1	6 8
Wedges	0	1·4
Cotters	0	7·1
Track labour, including curve	2	6 0
Rails, etc., carting	0	1·1
Packing rails (labour)	0	11·0
Half-inch unscreened granite shingle	1	0·0
Cement	0	11·5
Team labour	0	3 2
	19	5·4

Girder System.	£	s.	d.
Rails	0	15	11·2
Fishplates	0	1	8 8
Marshall's patent joints	0	0	9 9
Bolts and nuts	0	0	5 4
Soleplates	0	1	0 3
Tiebars	0	0	2·8
Unscreened granite shingle	0	0	4·0
Cement	0	0	5·1
Labour (packing rails)	0	0	3·6
Road scrapings (for plastering rails)	0	0	0 6
Track labour	0	1	3·0
Team labour	0	0	1·6
Soleplates punching	0	0	1·9
Blacksmiths' work	0	0	1·3
Repairs to punches	0	0	1·9
	£1	3	1·4

Although it will be seen from the foregoing tables that the first cost of the Demerbe track is cheaper than the girder track, this point if not the most important. There is the cost of maintenance to consider, and judging from the condition of the Demerbe track in Leeds-road after six years' wear and tear, it does not appear that any repairs will ever be necessary during the life of the rail once it is properly laid. This life I should estimate to be about 20 years, whilst the girder rail has to be renewed in 16 years.

The opponents of the Demerbe system when they compare these rails with the girder type, state that the latter rail when laid on two supports will carry a heavier load than the Demerbe rail under the same conditions. This is quite true, but the Demerbe rail does not act, nor is it intended to act, as a girder. It is supported throughout its entire length by a ridge of concrete, and the rail merely acts as a metallic covering.

The advantages of the Demerbe system of tramway over other systems may be summarised as follows: (1) The system is simple, being composed of very few parts. It is also cheaper, and can be laid more quickly than the girder system. (2) The rail and concrete resist the heaviest loads without displacement, depression, or other alteration of the track. (3) The cost of maintenance of rails and paving is reduced to a minimum. (4) The tie-bars are constructed without rivets or nuts. No punching or drilling of the rails is therefore necessary, as the tie bars can be fixed to any part of the rail by means of the slots. (5) Curves of quick radii are made at the works, and are laid as quickly as straight track. (6) The concrete support effectually prevents water finding its way under the rail.

Having regard to the very large sums spent annually on tramways maintenance, it is of the highest importance that lines should be constructed on a system which promises the longest working life, with a minimum of cost for repairs. The writer after a considerable experience in tramway construction and maintenance, has no hesitation whatever in affirming that the Demerbe system possesses points which place it far before the girder and other systems, and he can confidently commend it to the consideration of those having in any way to do with the development and extension of facilities for public transport by means of tramways. And as Bradford is the only city in the United Kingdom which has tested the Demerbe system, it is perhaps not unfitting that this paper should form a contribution to the British Association when it holds its meeting in that city.

Discussion.

The first gentleman who spoke on Mr. Dawson's paper raised the question of how the system described by him affected the roadway. Was the upkeep of the road just round the tramway more difficult to keep in order than was the girder type of railway?

Mr. Alexander Siemens pointed out that with the Demerbe system a 71lb. rail was used, as against 105lb. rail on the girder system. He noticed that in spite of this the cost was not so widely different.

Mr. Dawson, in reply, said that the roadway could be kept in order much more easily with the rails laid on the Demerbe system. This was because the granite sets did not tend to work loose in the same way as they did when laid on the under flanges of a girder rail. The vibration of the girder rail then tended to loosen the granite sets very considerably.

FORTHCOMING EVENTS.

Sept. 18 21.

Iron and Steel Institute.—Paris meeting, Sept. 18, 19, 20, and 21

Sept. 17.—Secretaries' office opens at the Société d'Encouragement pour l'Industrie Nationale, 44, Rue de Rennes, at 3 p.m. 6 p.m., meeting of council at Mr. Henry Chapman's office, 10, Rue Laffitte.

Sept. 18.—9.30 a.m., reception of the president in the hall of the Société d'Encouragement; reading and discussion of papers. 2 p.m., visit to the Exhibition. 9 p.m., Soirée Musicale et Littéraire by the Comité des Forges de France.

Sept. 19.—9 30 a.m., general meeting in the hall of the Société d'Encouragement; reading and discussion of papers. 2 p.m., visit to the Exhibition. 7.30 p.m., the Institute entertains the Reception Committee at a banquet at the Hôtel Continental, Rue Castiglione.

Sept. 20.—10 a.m., visit to the exhibition at Vincennes (locomotives, railway plant, and machine tools). 8 p.m., Group A will start for the St. Chamond Works. 10 p.m., Group B will start for the Hayange Works.

MUNICIPAL TRADING AT THE BRITISH ASSOCIATION.

The energy of mankind is largely directed by what concerns the individual Ego; hence the necessity at times for looking behind the scenes in order to obtain an insight into the true origin of action. The world has need of the two classes—the one with whom Ego reigns supreme forming the great bulk of extremists, the other a class having obtained more or less powers of reasoning forming the moderates. The gradations, however, between the extremists on the one side to the extremists on the other side are almost co-extensive with the number of individuals. Thus it comes naturally that most men look upon a particular question from the point of view how it affects the individual, and each conclusion is in this way unconsciously biassed. Points which do not seem to concern anybody in particular are not readily examined, and, indeed, in many cases are not examined at all. What real information as to the incidence of rating is given in Mr. Priestman's statement, similar to what has been often given before, that "the debt incurred by local authorities had increased from £60,000,000 in 1868 to £262,000,000 in 1898; and of this £87,500,000 was estimated to be on account of municipal trading." These figures and many others are given (corrected to date) in the annual reports of the Local Government Board. Frequently the amount per head of population is stated for the purpose of showing how small is the amount per head. It seems never to have struck these amateur statisticians that the amount per head of population is misleading, and what is far more to the point the amount per responsible head—that is, per person responsible for interest or repayment—is never stated. The total population includes men, women, and children. Even taking the population as consisting only of men and women, the divisor would be two, assuming that every man was responsible for his proportion of the debt. But this we know is not the case, and probably a truer number for responsible population would be to divide by six or eight, getting rid of irresponsible women, children, paupers, etc. A still further and a very large reduction must be made for the population residing in districts which have no debt. Then, again, the incidence of rating must be applied to every individual district, and not divided equally over the responsible population of the whole country. Taking round figures for an example, and assuming Cardiff to have a total population of 128,000, and a local indebtedness of about £2,000,000, the number of responsible ratepayers dividing by eight will be 16,000, giving a local indebtedness of £125 per head, a vastly different figure to the not quite £2 per head of population given in popular lectures. Arundel has a population of about 2,700, a debt of about £8,500, or a debt per head of responsible population of less than £25. Not long since, hoping to get trustworthy figures to put before the joint committee, we sent a circular to every authority in the country asking for official figures relating to population and indebtedness, but while obtaining many hundreds of replies, a large number of those authorities whose indebtedness is

Digitized by Google

greatest refused the information, not a few suggesting that if the committee wanted the figures they could compulsorily obtain them. The sting of accurate figures no doubt is in the fact that success in trading is not always assured, and those who indulge in trading should have some approximate knowledge of their real liabilities. We would suggest that all those who can obtain access to authoritative figures should find out the indebtedness per pound ratable value, so that every ratepayer would have some idea as to how far his credit is in pledge.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTROMAGNETIC INDUCTION.

SIR,—I have no desire that my critics should "temper justice with mercy," but I certainly think your correspondent, Mr. F. Johnston, might have tempered his want of mercy with a little justice. He says: "Mr. Dunton . . . describes the case of a rectangular coil of wire having its plane parallel to a uniform magnetic field; and then, after asserting, what is most obviously true, that there will be no current generated in the coil under these conditions, evidently thinks that he has proved his case." He then goes on to show that the statement to which I object does not imply that there will be a current under such conditions, and that I have therefore "found a veritable mare's nest." Now this apparently crushing reply is founded upon a gross misrepresentation; for my argument was not that there will be no *current*, but that "there will be no *E.M.F.*" Strange to say, in another part of his letter he quotes these very words of mine, which makes it somewhat difficult to believe that his misrepresentation is the result of a mere oversight.

Mr. Johnston further says: "Remembering that the so-called 'lines of force' are simply graphical means of representing the direction or 'grain' of the medium or state known as the magnetic field, it is evident that the E.M.F. impressed on a conductor, whether it be in the shape of a rectangle or not, is dependent on the density of that field and the rate at which the conductor cuts it at right angles to its direction." This is the most shocking case of *non sequitur* that I have ever met with; even if the second proposition is true, it certainly does not follow as a logical consequence of the first. Further, the first is not true, for the lines represent the strength of the field, not simply its direction.

My contradiction of the statement which Mr. Johnston upholds is based on the authority of Faraday, who holds that the cause of an induced current, or of a tendency to such a current, is the linking or unlinking of magnetic lines into or out of the electric circuit. I quite admit the possibility of Faraday being wrong and Mr. Johnston being right, but the theory put forward by Faraday strikes me as being by far the more probable one. However, the question could be decided by an experiment.—Yours, etc.,

Stockwell, S.W., Sept. 8, 1900. W. F. DUNTON.

LOCK AND BLOCK SIGNALLING.

The report of the Board of Trade inspector, Lieutenant-Colonel Yorke, on the enquiry into the causes of the accident on the North British Railway near Charing Cross Station, Glasgow, in March last, by which seven persons lost their lives and over 30 others were injured, has just been issued. Colonel Yorke places the responsibility for the disaster upon the signalman on duty at the time at Charing Cross box, and assigns as the immediate cause the use of apparatus under conditions which were demonstrated by the accident as improper.

The line is worked under the "lock and block" system of signalling, and the conditions leading to the accident were as under: Train A immediately on passing Charing Cross box found some difficulty with the brake, and stopped in consequence before reaching the advance clearing treadle for the box named. The signalman at the rear box had train B waiting there, and intimated the fact to Charing Cross. The latter found he could not clear the rear section as his instrument was locked. He seems to have immediately assumed that the passage of train A had failed to operate the treadle; and, taking the releasing key provided for use under exceptional circumstances, unlocked the instrument for the rear section, cleared the line and accepted train B, with the consequences already detailed.

On the advantages of "lock and block" working over the ordinary form of signalling there is no occasion to dwell now. Yet, here, where such a system is in regular use, and where the apparatus appears to have worked exactly as it was devised to do, the conditions obtaining are such as permit a signalman to commit an error of the first magnitude, and of precisely the same class as if the apparatus provided no special check upon error.

That releasing keys introduce a weak point in an-otherwise admirable system of checks against error is not new, and they have before now been pointed to as violations of the fundamental principles underlying the "lock and block." Their use is, no doubt, hedged about with regulations, and requirements in the way of explanations, but it must not be forgotten that, given the opportunity of use at will without positive check, no regulations, however stringent they may be, or appear to be, will repair the mischief that may arise from use under misapprehension. As criminal intention is absurd as an assumption for certain actions, the train of circumstances must initially be ascribed as due to a misapprehension.

It is a fundamental principle of railway signalling that failure of apparatus should not cause danger of accident, but should result in delay to traffic only. In ordinary signalling failure of apparatus leads to working being carried on at "Caution," and "lock and block" systems should not be exempted from the same rule. Suppose the treadle had failed, as was assumed in the case under notice, the use of the releasing key would not have repaired it. The traffic would have been facilitated undoubtedly, but the preventive check, which is the sole reason for the use of the particular class of apparatus, would be absent, and if apparatus temporarily fails in the function which constitutes its superiority over other apparatus under normal conditions, surely such failure is justification for altered conditions of working to meet the less efficient checks available. Moreover, if there are means for obviating the natural results of such a defect, there is a tendency to regard the repairs as of no particular urgency, and the dangerous conditions are prolonged.

The fact is, of course, the provision of a releasing key is a confession of the inability of the apparatus to meet all the conditions of railway working. They are, of course, useful in other ways than for bridging over defects, as, for instance, when cancellation is necessary. But traffic should hold second place to safety, and if such dangers as are here considered exist, it would seem desirable that the use of such auxiliary apparatus should be discontinued. In all probability it would be found that under rigid supervision and closer enquiry the necessity for their use is more apparent than real. Where it is easy to rectify a mistake, it is often considered unnecessary to aim at great accuracy.

It may also be noted that the usual suggestion for making special releasing of the instrument safe—concurrent action on the part of the two signalmen concerned—would have failed in the Glasgow case, since the man at whose instance the operation would have been undertaken failed to realise the cause for the instrument remaining locked, and the other man, who would be a party to the operation, would have no means of checking the statements made to him.

Other questions than those referred to might be discussed with advantage—the extremely prompt resort to the releasing key on the assumption that the treadle had failed is significant—but not now. The accident, deplorable as it is, cannot fail to draw attention to the subject. Regarded as a test of the principle of lock and block signalling, the apparatus may with truth be said to have done better than

Digitized by Google

its manipulator and director, and should stimulate confidence in its ability to prevent such accidents if the fatally easy means of nullifying its checks in the direction of safety are not provided.

ON THE APPARENT EMISSION OF CATHODE RAYS FROM AN ELECTRODE AT ZERO POTENTIAL *

BY CHARLES E. S. PHILLIPS

It has been noticed by many people who work with X-ray or other vacuum bulbs that numerous bright green patches occasionally appear upon the inner surface of the glass walls of a bulb while a discharge is passing, especially during the process of exhaustion. These green flecks vary considerably from time to time both in shape as well as in position, and efforts have been made to connect their existence either with want of uniformity in the composition of the glass or with irregularities in the surface of the negative electrode. I have already, in another place, given some account of an experiment made with the object of clearing up this uncertainty, and now beg to supplement that work with the following observations as to the cause of the phenomenon. The experiment just referred to consisted in using a pivoted disc of aluminium as the negative electrode in a bulb containing rarefied air, so that when green patches appeared a rotational movement of the disc (actuated by means of an external magnet) would show whether the patches of green moved in a corresponding manner or not. It was seen that they did so move.

A distinct feature of the experiment, however, consisted in ascertaining whether these flecks which persisted after the discharge had ceased were still sensitive to movements of the cathode. This also was found to be the case. The proof, therefore, that the green patches were associated with an emission from the cathode appeared complete. But it was further noticed that subsequent to the passage of a discharge, and even when either or both of the electrodes were connected to earth, still the green flecks were easily visible upon the glass walls of the bulb, and continued to move as before when the cathode was rotated. This was apparently a case in which cathode rays were emitted from an electrode at zero potential.

I do not know that any explanation of this effect has so far been offered, and I therefore venture to bring forward the following suggestions, supported by further experiments. When a piece of metal is placed in a rarefied atmosphere and made the negative pole for an electrical discharge passing across the attenuated gas, innumerable small bright specks of light appear over the surface of the metal. It was found convenient in my particular case to use an iron electrode for observations of this effect, because it had the advantage of being readily magnetisable from without. The addition of a similar iron electrode to act as the anode determined the shape of the magnetic field. With such an apparatus it could be seen that the bright spots appeared principally upon the cathode while the discharge passed, and that the creation of a magnetic field between the electrodes made visible the individual luminous streams of gas emanating from those tiny points of light. The paths of these luminous streams becoming bent by the action of the magnetic field followed the direction of the lines of magnetic force, and exhibited a tendency to become spiral in accordance with well-known laws. In this way a fine layer of sodium upon the anode was caused to fluoresce through the action of the negatively electrified particles beating down upon it. One was able, in fact, by this means to cast shadows of objects placed in the paths of the bent streams, and at a pressure considerably higher than that necessary for the production of the well-known cathode shadow effects. In the above case, however, the method served to clearly establish the fact that the bright points of light upon the surface of the cathode indicated the places from which the jets of gas originated. The number of these jets became less as the exhaustion was continued, and individual streams were very clearly seen owing to the action of the magnetic field. When the discharge began to cause fluorescence in the glass of the bulb some green patches made their appearance, and, in some cases, when the cathode was magnetised a bright spot, which was previously judged to indicate the origin of a green patch upon the glass, would shift to a new position upon the electrode. In all such cases the corresponding patch also moved in a similar manner upon the glass. At sufficiently high exhaustions the bright spots upon the electrode disappeared entirely, although green flecks were still visible upon the glass. But a movement as before of the electrode, as well as its magnetisation, gave results consistent with previous observations. Under these conditions, when the discharge through the bulb was stopped, green flecks were still visible for about ten seconds. A positively charged body was brought up to the outside of the bulb and the patches brightened considerably. A negative charge similarly placed extinguished the flecks completely. This was also the case when the electrodes were connected to earth.

Finally, vacuum bulbs, such as X-Ray lamps, etc., exhibiting green flecks while in operation, were generally found to deteriorate if laid aside for a month or two, owing to an increase in the pressure of the contained gas. We see, therefore, that, in the first place, the bright points of light upon the surface of the cathode are due to the emission of fine jets of gas; also that such jets, if negatively charged, may be made to cast shadows of objects suitably placed in their paths. It is, at the same time, clear that the green flecks referred to above are due, during the passage of a discharge, to these same jets of gas impinging upon the inner side of the glass walls, and that, under the conditions existing immediately subsequent to the passage of the discharge, it is evident that streams of gas continue to be emitted from the pores of the electrodes. In spite of the fact that with the electrodes connected to earth these streams consist of unelectrified particles, they assume that property of ionisation during their passage across the space within the bulb which appears to be essential to the production of local fluorescence in the glass upon which they impinge. This latter effect, while explaining the process by which a cathode emission may appear to originate at an electrode with no electrical charge upon it, is one to which I wish to draw special attention, for there is reason to believe that the upper limit of speed for the individual particles constituting the jets cannot exceed the rate at which sound is propagated. It is, therefore, interesting to find that, under such circumstances, fluorescence was produced in the glass upon which the streams impinged.

As many of the observations referred to here were made during the course of an investigation into the diselectrifying action of magnetism now being carried out by myself at the Davy-Faraday laboratory of the Royal Institution, I desire to express my indebtedness to the managers of that institution for the facilities which they have kindly placed at my disposal.

* Paper read before the British Association at Bradford.

Discussion.

Prof. Fitzgerald commented on the results obtained by the author, and wondered if the radiation from the electrode connected to earth would still continue if it were taken out of the vacuum.

Prof. Lodge thought that the glass must have something to do with the effect observed, in spite of the fact that the luminous spots revolved when the electrode was rotated. It was an exceedingly difficult subject to investigate. With respect to the alteration of the vacuum in X-ray tubes with time, he wondered if the author had noticed any tubes being spoilt by the vacuum increasing.

Mr. C. E. S. Phillips, in reply, said he did not fancy there would be any action if the cathode were taken out of the tube. He had noticed that in certain cases the vacuum had gone up with time, although the tubes in question were not being used at all. There seemed to be an absorption into the glass of the gases, or else it would look as though the same were carried out through the glass by the discharges.

WIRELESS TELEPHONY.*

BY SIR WILLIAM HENRY PREECE, K.C.B.

The first experiments in this direction were made in the month of February, 1894, across Loch Ness, in the Highlands. On that occasion trials were made to determine the laws governing the transmission of Morse signals by my electromagnetic method of wireless telegraphy, which has formed the subject of frequent reports to this section since 1884. Two parallel wires well earthed were taken, one on each side of the lake, and arrangements were made by means of which the wires could be systematically shortened, with a view of ascertaining the minimum length necessary to record satisfactory signals. It occurred to Mr. Gavey, who was experimenting, to compare telephonic with telegraphic signals—i.e., to ascertain whether articulate speech could be maintained under the same conditions as Morse signalling. The trials showed that it was then possible to exchange speech across the loch at an average distance of 1½ miles between the parallel wires, when the length of the wires themselves was reduced to four miles on each side of the water. What led to this train of thought was the fact that, although the volume of a telegraphic current was immensely greater than that of a telephonic current, whenever through want of balance in a loop disturbance was evident, then telephonic cross talk was also manifest. In other words, a weak telephonic current was apparently as powerful a disturber as a strong telegraphic one.

The sensation created in 1897 by Mr. Marconi's application of Hertzian waves distracted attention from the more practical, simpler, and older method. Mr. Evershed and Principal Oliver Lodge had in the meantime much advanced the system by introducing admirable call systems. In 1899 I conducted some careful experiments on the Menai Straits, which determined the fact that the maximum effects are produced when the parallel

* Paper read before the British Association at Bradford.

Digitized by Google

wires are terminated by earth-plates in the sea itself. It became quite evident that the ordinary inductive effects are much enhanced by conductive effects through the water, and that in consequence shorter wires are practical. No special apparatus seems necessary. The ordinary telephonic transmitters and receivers were used. It became desirable to establish communication between the islands, or rocks known as the Skerries, and the mainland of Anglesey, and it was determined to do this by means of wireless telephony. The lighthouse at the Skerries was wanted to be in communication with the coastguard station at Cemlyn, which is connected with the Post Office system. The bottom of the Channel is too rough, and the currents too violent for a cable. A wire 750 yards in length was, therefore, erected along the Skerries, and on the mainland one of 3½ miles from a point opposite the Skerries to Cemlyn. Each line terminates by an earthplate in the sea. The average distance between the parallel portions of the two wires is 2·8 miles. Telephonic communication is readily maintained and the service is a good one. Lodge's call system will be used.

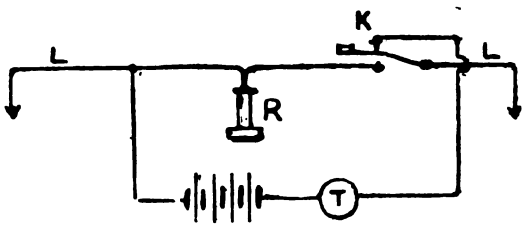

Diagram of Connections: LL = Line Wire earthed at either end. R = Telephone Receiver. T = Transmitter. K = A Key in receiver, which has to be depressed when message is being received.

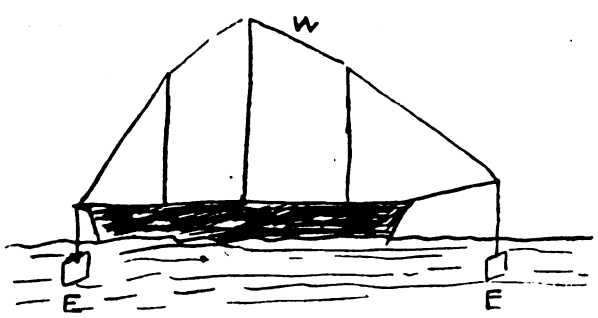
Further experiments with wireless telephony have recently been made between Rathlin Island, on the north coast of Ireland, and the mainland. The east and west portion of the island of Rathlin is about eight miles from the mainland, but a tongue of land projects southward to within a distance of four miles. Communication was required between the lighthouse near the north-eastern corner of the island and the mainland, and the question for solution was whether an overhead line running the whole length of the island from east to west was necessary to obtain good communication, or whether a shorter line across the neck of the southern peninsula would serve. The preliminary experiments that have been made proved conclusively that communication, both telegraphic and telephonic, has been readily maintained by means of temporary wires established across the neck of the peninsula along the shorter line. Wireless telephony across the sea is now a practical and commercial system.



W = Wires of sending and receiving circuit.
E E = Plates in the sea.

No experiments have yet been made with ships, but it would appear simple to speak by telephone between ship and ship, or between ship and shore, to considerable distances across space by means of a circuit formed of copper wire terminating at each end of the ship in the sea, passing over the topmast and using simple telephones.

Discussion.

In proposing a vote of thanks to the author, the **Chairman** called on Dr. Oliver Lodge to open the discussion on the important paper read by Sir W. H. Preece.

Dr. Oliver Lodge said that he had always urged the importance of having earthplates in the sea, as he had found that earth connections increased very much the range of such systems of telegraphy or telephony. It was surprising how small a base line between the earthplates was sufficient in such cases. Thus he signalled between his college and private house over a distance of two miles with an exceedingly small distance between the earthplates. When using the telephone as the sending and receiving instrument, he thought that good results were produced because the electrical energy was only distributed over two dimensions. The high frequency of the waves tended to keep the electricity on the surface, so that it did not diffuse downwards. When signalling between warships as suggested by Sir W. Preece, he was afraid that the arrangement of conductors over the mast and bowsprit of the ship ending in an earth plate fore and aft, would not be very successful. This would be perhaps all right with a wooden ship, but in an iron vessel the earth-plates would be almost short circuited by the mass of iron between them. It was exceedingly difficult, of course, to discriminate between the induction effects and the conduction currents, but he believed that a large proportion of the energy transmitted went by conduction.

Mr. Sydney F. Walker did not think that signalling from warships as suggested by Sir William Preece would be serviceable. He had some years ago investigated the lines of current flow in connection with signalling without wires. The results he had obtained were described in an article in the *Electrical Engineer* for Dec. 9, 1892.

Mr. Julius West said that in signalling from one ship to another, the relative angles would, he was afraid, make a great difference between the distances to which signalling was possible. He had experimented largely on a lake in Germany in order to determine whether signals were transmitted by induction or conduction. A line similar to the one described by Sir W. Preece was erected along the shore of the lake, ending in two earth-plates. The receiving line was connected between two yachts on the lake, one of these being anchored. The other yacht then moved round in a circle, and he found that when the two vessels were in a line perpendicular to the sending wire on shore, no signals were received. He concluded from this that the signals were sent by induction. *

Another speaker commented on the fact that a telephone connected between the gas and water service always gave a loud click when a flash of lightning took place in the neighbourhood.

Sir W. H. Preece, in reply, said that the effect noted by the last speaker was well known, although it was somewhat surprising, in view of the close proximity of the gaspipes and water-pipes. Telephones with an earth return always acted as recorders of thunderstorms. He remembered, for instance, that when the London to Paris telephone system was being inaugurated, the ladies and gentlemen who were at the London instrument were surprised to hear what seemed like a series of loud reports intermingled with the music and speech from Paris. These noises were due to a thunderstorm in France. Mr. Gavey had last year tried at Dover a most interesting experiment on the possibilities of signalling by means of the discharges from the clouds. When a violent thunderstorm was taking place he transmitted signals from the sending station of the Marconi telegraph to the Boulogne station without using the usual sources of electricity. The signals were received and were quite readable, although they were interspersed with interruptions caused by the violent discharges from the storm.

THE MANCHESTER AND LIVERPOOL EXPRESS RAILWAY.†

BY SIR W. H. PREECE, F.R.S.

A monorail line has been projected by Mr. Behr between Manchester and Liverpool to accommodate express passenger traffic alone between those two cities. It is to be worked by electric traction, and to attain very high speeds. The train is to consist of only one coach, weighing 45 tons and seating 64 passengers. Starting at every 10 minutes, and travelling at the mean rate of 110 miles an hour, it will do the distance of 34½ miles in 20 minutes. The fares will be slightly lower than those charged at present. There will be no intermediate stations, no points nor crossings. There will thus be no necessity for signals to protect the line during other operations. Signals would be needed only to secure a perfect block system of working the line. The monorail railway was projected by Lartigue in 1882. We have only one example of this system of railway in the United Kingdom—viz., between Listowel and Ballybunion, in County Kerry, Ireland. This line was designed and engineered by Mr. Behr. The Act was obtained in 1887 and the line was opened for traffic in February, 1888, and it has been running ever since. The line is 9¼ miles long. It has one intermediate station, Liselton. There are 42 level and farm crossings. It is worked by steam. The train consists of a locomotive and four coaches. It cost £33,000 to build, or £3,060 per mile. When I inspected the line in the early part of this year there had never been a Board of Trade enquiry into any accident. The maintenance of the structure had been effective. No rail had ever been turned. The mechanical structure had exhibited no defects, but several breakdowns had occurred in the locomotive and rolling-stock. There are three locomotives, 11 passenger coaches, and two brake vans. They had, however, continued to work the line uninterruptedly for 12 years, and there had been no renewals or new stock. Its main principle is the suspension of the coaches on a single elevated rail so that their centres of gravity are below the rail. Each coach sits the rail like a saddle. The rail is fixed on

* N.B.—It seems to us that Mr. West's experiment is not conclusive, as exactly the same would take place if the signals were transmitted by conduction only, and not by induction at all.—Ed., *E. E.*

trestles which are tied and braced together, the tie-bars being light rails against which guide wheels roll.

The Manchester and Liverpool express is intended to be more massively and rigidly built. Derailment on such a structure is impossible, and curves of comparatively small radius can be passed with safety at high speeds. Vibrations and noise will be reduced, and travelling will be conducted with greater comfort than at present. It is proposed to fix the generating station midway at Warrington, and to transmit the electric energy at high-pressure (10,000) volts to each terminal station. There would be sub-stations along the line at distances apart of four miles, where the 10,000 volts would be brought down to 1,000, at which pressure it would be picked up by the motors on the coach. The speed which a train can acquire on a railway depends on the power that can be continuously applied at the tread of the driving wheel. Electricity enables the engineer to apply instantaneously to light loads a power which steam cannot supply; hence speeds are possible with electricity which are unattainable with steam. A coach weighing 45 tons can easily and quickly attain 110 miles an hour; 1,600 h.p. will accelerate the coach so as to attain this speed in 110 seconds, and 500 h.p. will maintain this speed on the level. Electricity has two advantages over steam. It enables us to obtain an acceleration of 1½ft. per second, which is virtually the limit that can be obtained without causing discomfort to the passengers; and, secondly, it applies a continuous and constant torque instead of the variable one, due to the reciprocating action of the ordinary steam locomotive. Hence it not only enables us to maintain high speeds on long through lines like the proposed Manchester and Liverpool Express, but it enables us to attain high speeds with greater rapidity on short lines having frequent stoppages, like the Metropolitan Railways of London, and thus increase the capacity of the line for traffic. The chief causes of accident on ordinary railways—viz., collision, derailment, points, and the human error of the signalman will be removed from lines. Hence travelling will be much safer.

MANCHESTER AND LIVERPOOL RAILWAY: BRAKES AND SIGNALS.*

BY F. J. BEHR.

The question of brakes and signals are so intimately connected that the one cannot be treated separately from the other. The most perfect condition under which a railway could be worked, would be that in which both brakes and signals could be dispensed with, therefore it follows that the fewer the occasions for using either the better. Now as to brakes, there is a limitation of their application, which depends not so much on the mechanical appliances themselves as on the endurance of the human bodies in the trains. It was stated by an eminent railway official that with the Westinghouse brake, a train travelling at 60 miles an hour could be stopped, as an emergency brake, within 360 yards without inflicting too great a shock on the passengers. In the same way a train travelling at 110 miles an hour could be stopped within 500 yards, and probably in a shorter distance, as in the latter case electrical means are at hand, such as the reversal of the motors, so as to turn them into dynamos. More rapid stoppage could only be made with great discomfort to the passengers. Now in the ordinary way of working our railways at present there are many occasions in which it might be important to stop the train as rapidly as possible. For instance, if a train in front should be seen, or some shunting operations were not completed, or many others too many to enumerate, but no brake, however powerful, would be of the slightest use to-day to avoid a sudden obstacle, such as a stone placed on the rail, or a broken rail, for it is impossible for the driver to be aware of such obstacles until he is practically upon them. For these cases of great emergency, therefore, the stoppage at 300, or 200, or even 100 yards is quite useless.

What I wish to show now is that on the proposed high-speed electrical railways, though it is quite possible to brake the train within less than 500 yards, it never can be necessary to bring it to a standstill at even a much longer distance. On the proposed railway there are no level crossings, no switches, no shunting operations, and, in fact, nothing that will require the train to be brought to a standstill, except in the event that a preceding train should break down. Besides this one case, the brakes can only be used for stopping as you approach the stations. A broken rail offers no danger in this case whatever, for the train would run over it without any danger or difficulty. This can easily be shown by carefully considering the relative position of the wheels in the carriages to the rails over which they travel. I now, therefore, have only to explain the manner in which it is arranged that the driver of each train shall be informed of the possible stoppage of the train in front of him. No second train will leave the station at Manchester or Liverpool until the first has reached Warrington, a distance of just 17 miles. We subdivide the line for the purpose of signalling into eight sections of 4·3 miles each. As trains leave Manchester station a danger signal is put up automatically at that station, a second similar danger signal is put up in the same way at 4·3 miles off, the first remaining at danger. The train travels on until it reaches 8·6 miles, when it puts up a third danger signal, and simultaneously the signal is lowered at Manchester or Liverpool station, so that the second train can leave when the time comes. Now, we will assume that the first train has met with an accident after passing point 8·6 miles, the second train would travel at a higher speed right on, but when it passes point 4·3 miles the danger signal at that point not having been removed by the first train, as this never reached point 13 miles, the driver of the second train would be informed that the first train had met with an accident beyond 8·6 miles, and therefore that he had to slow down, but that for such lowering of his speed he had a clear run of over four miles. Therefore, there could be no difficulty in any case to stop even without using the brake at all, by simply cutting off the current. Whenever a train passes over a point where the danger signal is put up this is also produced, either electrically or mechanically, by a very simple and inexpensive contrivance in the cabin of the electrician, so that he should be perfectly able to see it without difficulty even if there was a thick fog.

Under these conditions of travelling it seems, therefore, superfluous to have any emergency brakes, and though we shall be able to stop the trains within 500 yards, no case can be imagined in which it would be useful or necessary to resort to such a stoppage. A six minutes' service of trains can be established without any alteration in the proposed arrangement, and if a three minutes' service was required, the blocks would have to be reduced to two mile sections, giving a clear run of two miles in case of a breakdown.

* Paper read before the British Association at Bradford.

Discussion.

The President announced that the discussion on the papers read by Sir W. H. Preece and Mr. F. J. Behr would be taken together, as they referred to the same subject.

Mr. Jas. Shoolbred asked if they could not be given more details as to the reason why the House of Commons Committee had refused to pass the Bill. He understood that though both the Dock Board and the Salford Corporation had successfully objected, there was also the question raised by the committee of the brakes and of the general safety of the system. Could the authors give any information on the air friction of trains at such high speeds. He understood that in America recently some experiments had been made on the air friction caused by the gaps between the carriages. Speaking from memory, he thought that the air friction was reduced by 40 per cent. by boarding up these spaces. He was surprised to find that the bogie carriage proposed to be used would weigh 20 tons, which would be practically double the weight of an ordinary passenger bogie.

Mr. Behr, interposing, explained that the weight of a carriage was not the thing to be considered, but rather the weight per passenger carried. On the proposed Liverpool and Manchester express this weight would be 12cwt. per passenger, whereas on one of our principal railways the weight came out at 1¼ tons per passenger.

Mr. Sydney F. Walker referred to the enormous advantage on such a system of the use of polyphase transmission, which had so many advantages over continuous current. He proceeded to refer to some experiments by Prof. Weber on the capability of the human body to withstand shock. The professor had found that 50 volts was sufficient to paralyse him when passed through from hand to hand, the hands being moistened. With dry hands 90 volts alternating had the same effect. When the current was passed through from head to feet, standing on gravel, a shock of 2,000 volts could be taken, but on wet clay the professor was paralysed at 1,300 volts.

Mr. Behr, in reply, said that he thought the present paper would answer any objections brought by the committee on the braking question, but the braking question was, after all, not for the committee to decide, but for the Board of Trade, who had full control of this matter, and also of the safety of the public from shock. They had used 750 volts without doing any damage in Brussels, and he thought the step to 1,000 volts was quite justifiable. One of the great dangers from high speeds resulted from the coupling of carriages, which they avoided by having single cars only. The single cars also gave great economy and enabled them to run a frequent service. The question of the number of people carried by the railways now connecting the two cities of Manchester and Liverpool had not been cleared up before the committee. The railway companies said that the traffic did not pay, and that they only carried 1,500 per day. He had counted up to 4,000 per day, but even then the number travelling depended on the facilities given, and he expected that their estimate of 7,500 passengers was none too high. The company could, however, pay a dividend of 15 per cent. when carrying 4,000 per day. In answer to another question Mr. Behr stated that the centre of gravity of the cars was 15in. below the top of the rail.

Sir. W. H. Preece, also in reply, thought that the figures referred to by Mr. Walker must have been wrongly given in the

Digitized by Google

foreign paper in which they appeared. A shock of 200 volts would not paralyse anyone, and he thought that 500 volts was absolutely safe.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

307. To what extent would the capacity of a compound or shunt machine be affected when working in extremes of temperature, such as are experienced on some ocean liners? Give the ratio.—F. W. G.

308. In providing condensing plant for a central station, what should be the governing factor in deciding the size of the plant? What is the mistake so often made?—A. G. M.

ANSWERS.

Question No. 301.—In installations on board ships working with only one insulated wire, and using the ship as the return, which pole of the dynamo should be connected to the ship?

Answer to No. 301 *(awarded 7s. 6d.)*.—In a two-wire circuit carrying direct current it is found that the negative wire tends to assume earth potential. This is due to the rapid deterioration of insulation brought about by what is known as electric osmosis. By reason of this action any moisture present tends to move from the positive and collect round about any exposed connections to the negative wire. As all insulation is more or less porous, this creeping action is not confined solely to the leakage surfaces. This condition of things is naturally more pronounced in connection with ship lighting than in ordinary installation work. As the negative wire approaches earth potential this destructive action becomes less marked, and can be prevented to a large extent by deliberately earthing the negative wire. In many cases, therefore, the negative wire has been dispensed with and the hull of the ship used as a return. This, of course, reduces the cost of wiring, so that more may be spent upon the insulation and installing of the remaining wire. Greater security from fire risk, and other advantages outside the scope of this question, accrue from the use of this single-wire system. If, however, the positive pole were connected to the ship instead of the negative, the detrimental action on the insulation of the negative would not only be maintained but intensified, until eventually the system would break down altogether. This end would be hastened by electrolytic action, which would be set up wherever leaks should happen to occur. The ironwork of the ship would become pitted at these points, and the wire itself be unfavourably acted upon. If lead-covered wire were used, the sheathing being electro-positive to the wire would quickly be corroded. It is therefore very evident that the negative pole ought to be connected to the ship rather than the positive.—P. S. T.

Answer to No. 301 (*awarded* 7*s.* 6d.).—In single-wire ship installations it is advisable to connect the negative pole of the dynamo to the ship. The reason for this is that it is impossible to make the connections between the wiring and the hull so perfect as to do away with electrolytic action. This electrolytic action takes place between the copper of the conductors and the iron of the ship; the presence of salt in the moisture which collects on the sides and bulkheads of the vessel (due to "sweating") causes the electrolysis to proceed very rapidly where an imperfect connection exists. When the negative pole of the dynamo is connected to the ship, the current from the various small connections for the lamps flows from those connections to the ship, and tends to clean the copper at the contact, as it is constantly being eaten away to a greater or less extent. Of course, the reverse effect takes place at the negative pole of the dynamo, where the current, leaving the ship, enters the main negative cable to the dynamo. As it is, however, much easier to make and maintain a good connection in the case of one large cable than it would be to make and maintain a good connection at all the various small lamp connections scattered throughout the ship, the advantage of having the negative cable connected to the shell is obvious. The reduction in the resistance due to the above method of connection is, of course, only a small amount for each joint, but when this small reduction is multiplied by, say, 200 or 300, the total reduction is an important factor.—R. M. W.

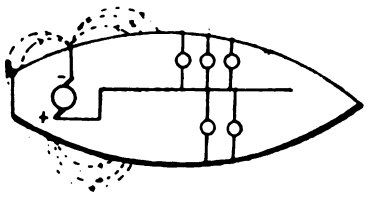
Answer to No. 301 (*awarded* 5*s.*).—The negative pole of the dynamo must be fastened to the ship in order to avoid damage to the ship by electrolytic action. A little experiment will make this perfectly clear—viz.: Take two small copper wires (No. 20 or No. 18 will do nicely), and attach one to the negative pole and one to the positive pole of a battery of not less than two cells in series, then dip the two free ends into a cup containing sulphuric acid solution (10 per cent. acid and 90 per cent. water will do nicely), and allow the current to pass for a little while. Now examine the ends of the wires dipped into the acid solution, and it will be obvious that the wire attached to the positive pole of the battery has been dissolved away more or less according to the strength of the current and the time allowed for the experiment. With a dynamo instead of a battery the current would probably be greater, and therefore the damage done to the wire would be greater and more rapid. A solution of salt and water would have the same effect on the wire—*i.e.*, the free end of the positive wire would be eaten away. In electrolysis the metal passes in the same direction as the current, and any acid in the electrolyte passes in the opposite direction, and so attacks the positive electrode. At sea the ship would seldom be dry for long, and therefore damaging electrolytic action would be certain to occur to the ship if the positive pole of the dynamo were attached to it, but with the ship attached to the negative pole all tendency to damage the ship is obviated, and the tendency to damage or corrosion by electrolytic action is transferred to the positive wire, which can easily be protected by insulation.—F. G. A.

Answer to No. 301 (*awarded* 5*s.*).—Assuming in the first case the + pole to be connected to the ship and the − pole to the insulated wire, then if leakage caused by dampness takes place between the bare metal parts of the insulated wire (such as switches, lampholders, etc.) the leakage will tend to increase. This effect is due to what is known as electric osmosis—*i.e.*, moisture will constantly creep from the ship (+) to the fault on the insulated wire (−) reducing its insulation resistance and thus increasing the leakage current. But, in the second case, if the − pole be connected to the ship and the + pole to the insulated wire, then a leakage current from the insulated wire which is now + will cause moisture on it to creep to the ship which is −, increasing the insulation resistance of the insulated wire. Thus, in order to keep good insulation between the insulated wire and the ship, the − pole should be connected to the ship.—A. H. M.

Answer to No. 301 (*awarded* 5*s.*).—If the metal work of the ship forms a complete and uninterrupted circuit, as is usually the case, from one pole of the dynamo to all lamps or other apparatus in use, there is no preference as to which pole should be connected to the ship. The case cannot be compared with the ordinary single-trolley tramway circuit, in which the earth return is usually made the negative. In the case of the ship, leakage from + to − will not pass into the sea at all, but will be entirely confined to the inside of the ship. There is, however, a likelihood of leakage occurring locally through the sea on the outside of the ship from points working at higher potentials to other points working at lower potentials. On this account it would be worth while changing the dynamo leads over every few weeks or months, so as to make the ship some-

Digitized by Google

times negative and sometimes positive. In this way damage to the ship's plating will be prevented. For, whilst the ship's side is the negative pole, the leakage current will flow in one direction, depositing metal off one point and on to another (as shown by the dotted lines in the figure), and



when the polarity is reversed the direction will be reversed, and the deposition will take place in the reverse direction, thus tending to repair the damage done with the first polarity.—Q.

Question No. 302.—How would you determine the proper size and lifting power of a travelling crane for an electric generating station?

Best Answer to No. 302 (*awarded* 10*s.*).—The size and lifting power of a crane for an electric generating station is governed by the weights it will be called upon to lift during the erection of the plant, and in case of any repairs cranes in central stations should be designed very liberally, for most growing stations find that when a unit of 100 kw. is used at the commencement it is most economical to adopt a 500-kw. unit as the load on the station increases. Now, if a bare margin is only allowed a new crane will have to be erected, and it would have paid to put up a larger crane at first. Where the load is assured, and the commencing unit is a standard, as in traction plants, the crane must be designed with a 50 per cent. allowance above the heaviest weight to be dealt with. The following table is taken from modern central station practice:

Size of units.	System.	Strength of crane.
80 h.p.	Direct	6 ton.
120 h.p.	Direct	8 ton.
500 h.p.	Direct	10 ton.
180 h.p.	Alternating	10 ton.
750 h.p.	Alternating	20 ton.
750 h.p.	Three-phase	25 ton.

This shows the strength of cranes which are advised by our prominent consulting engineers. The 180-h.p. set and the 750-h.p. set are engines with slow speed, all others high speed. In the two latter sizes the crane was operated by electricity, and where heavy castings have to be moved the electric cranes are an advantage, being easily controlled and quicker in their action than a crane operated from the engine-house floor by means of chains. The table beneath shows crane speeds under various loads:

Load	5	10	15	25 tons.
Hoist	151	10	8	6ft. per minute.
Traverse	90	50	45	45ft. ,,
Travel	100	100	100	100ft. ,,

The horse-power of a crane motor is arrived at by taking the actual power used in lifting a load, and allowing 25 per cent. for power lost in gearing; for cast wheels in the gearing a higher figure than 25 per cent. must be taken. A slow-speed motor on a crane, although higher cost, is better than higher-speed machines; in the former no wear and tear of gearing takes place, and they possess quicker reversing power. Speeds should be kept down in a three-motor crane to 300 per minute for hoist and 700 per minute for travelling. I advise a single-motor crane for this class of work controlled by a main switch. A resistance in series with the shunt will give variation in speed.—F. M. M.

Answer to No. 302 (*awarded* 5*s.*).—Cranes for central-station work are designed in many cases with three motors instead of one, so as to obtain the highest economy of power in working, and at the same time to avoid the complications of gearing which is necessary with the single motor type of crane. The proper size and strength is determined by the following items: (1) the maximum weight to be lifted, and at what speed; (2) speed of cross traverse for maximum load; (3) speed of longitudinal traverse; (4) maximum height to be lifted; (5) the span, or distance from centre to centre, of rails and total length of gravity.

Thus suppose the maximum weight to be lifted be five tons, and the speed of elevation to be 10ft. per minute, then the work done in one minute will equal $2,240 \times 5 \times 10 = 112,000$ foot-pounds $= 3{\cdot}39$ horse-power, which will have to be developed at the point of suspension. Thus the motor should have a brake horse-power of 3·4, plus any loss due to friction and gearing. Then having arrived at the brake horse-power necessary, and knowing the available E.M.F., we can calculate the current that the motor will take, which thus gives us the amount of copper, and the weight of the motor can be calculated, which will be a dead weight, for which allowance must be made in arriving at the strength of the crane frame.—J. C. B.

THE BRITISH ASSOCIATION.

Address to the Mathematical and Physical Section

BY JOSEPH LARMOR, M.A., D.SC., F.R.S., PRES.C.P.S., PRESIDENT OF THE SECTION.

(*Concluded from page 341.*)

If, then, we have so small a hold on the intimate nature of matter, it will appear all the more striking that physicists have been able precisely to divine the mode of operation of the intangible æther, and to some extent explore it in the fields of physical influence of the molecules. On consideration we recognise that this knowledge of fundamental physical interaction has been reached by a comparative process. The mechanism of the propagation of light could never have been studied in the free æther of space alone. It was possible, however, to determine the way in which the characteristics of optical propagation are modified, but not wholly transformed, when it takes place in a transparent material body instead of empty space. The change, in fact, arises on account of the æther being entangled with the network of material molecules; but inasmuch as the length of a single wave of radiation covers thousands of these molecules the wave-motion still remains uniform and does not lose its general type. A wider variation of the experimental conditions has been provided for our examination in the case of those substances in which the phenomenon of double refraction pointed to a change of the æthereal properties which varied in different directions; and minute study of this modification has proved sufficient to guide to a consistent appreciation of the nature of this change, and therefore of the mode of æthereal propagation that is thus altered. In the same way, it was the study and development of the manner in which the laws of electric phenomena in material bodies had been unravelled by Ampère and Faraday, that guided Faraday himself and Maxwell—who were impressed with the view that the æther was at the bottom of it all—in their progress towards an application of similar laws to æther devoid of matter, such as would complete a scheme of continuous action by consistently interconnecting the material bodies and banishing all untraced interaction across empty space. Maxwell, in fact, chose to finally expound the theory by ascribing to the æther of free space a dielectric constant and a magnetic constant of the same types as had been found to express the properties of material media, thus extending the seat of the phenomena to all space on the plan of describing the activity of the æther in terms of the ordinary electric ideas. The converse mode of development, starting with the free æther under the directly dynamical form which has been usual in physical optics, and introducing the influence of the material atoms through the electric charges which are involved in their constitution was hardly employed by him; in part, perhaps, because, owing to the necessity of correlating his theory with existing electric knowledge and the mode of its expression, he seems never to have reached the stage of moulding it into a completely deductive form. (In 1870 Maxwell, while admiring the breadth of the theory of Weber, which is virtually based on atomic charges combined with action at a distance, still regarded it as irreconcilable with his own theory, and left to the future the question as to why "theories apparently so fundamentally opposed should have so large a field of truth common to both."—"Scientific Papers," ii., p. 228.)

The dynamics of the æther—in fact, the recognition of the existence of an æther, has thus, as a matter of history, been reached through study of the dynamical phenomena of matter. When the dynamics of a material system is worked up to its purest and most general form, it becomes a formulation of the relations between the succession of the configurations and states of motion of the system, the assistance of an independent idea of force not being usually required. We can, however, only attain to such a compact statement when the system is self-contained, when its motion is not being dissipated by agencies of frictional type, and when its connections can be directly specified by purely geometrical relations between the

Digitized by Google

co-ordinates, thus excluding such mechanisms as rolling contacts. The course of the system is then in all cases determined by some form or other of a single fundamental property, that any alteration in any small portion of its actual course must produce an increase in the total "action" of the motion. It is to be observed that in employing this law of minimum as regards the action expressed as an integral over the whole time of the motion, we no more introduce the future course as a determining influence on the present state of motion than we do in drawing a straight line from any point in any direction, although the length of the line is the minimum distance between its ends. In drawing the line piece by piece we have to make tentative excursions into the immediate future in order to adjust each element into straightness with the previous element; so in tracing the next stage of the motion of a material system, we have similarly to secure that it is not given any such directions as would unduly increase the action. But whatever views may be held as to the ultimate significance of this principle of action, its importance, not only for mathematical analysis, but as a guide to physical exploration, remains fundamental. When the principles of the dynamics of material systems are refined down to their ultimate common basis, this principle of minimum is what remains. Hertz preferred to express its contents in the form of a principle of straightness of course or path. It will be recognised, on the lines already indicated, that this is another mode of statement of the same fundamental idea; and the general equivalence is worked out by Hertz on the basis of Hamilton's development of the principles of dynamics. The latter mode of statement may be adaptable so as to avoid the limitations which restrict the connections of the system, at the expense, however, of introducing new variables; if, indeed, it does not introduce gratuitous complexity for purposes of physics to attempt to do this. However these questions may stand, this principle of straightness or directness of path forms, wherever it applies the most general and comprehensive formulation of purely dynamical action: it involves in itself the complete course of events. In so far as we are given the algebraic formula for the time integral which constitutes the action, expressed in terms of any suitable co-ordinates, we know implicitly the whole dynamical constitution and history of the system to which it applies. Two systems in which the action is expressed by the same formula are mathematically identical, are physically precisely correlated, so that they have all dynamical properties in common. When the structure of a dynamical system is largely concealed from view, the safest and most direct way towards an exploration of its essential relations and connections, and, in fact, towards answering the prior question as to whether it is a purely dynamical system at all, is through this order of ideas. The ultimate test that a system is a dynamical one is not that we shall be able to trace mechanical stresses throughout it, but that its relations can be in some way or other consolidated into accordance with this principle of minimum action. This definition of a dynamical system in terms of the simple principle of directness of path may conceivably be subject to objection as too wide; it is certainly not too narrow; and it is the conception which has naturally been evolved from two centuries of study of the dynamics of material bodies. Its very great generality may lead to the objection that we might completely formulate the future course of a system in its terms without having obtained a working familiarity with its details of the kind to which we have become accustomed in the analysis of simple material systems; but our choice is at present between this kind of formulation, which is a real and essential one, and an empirical description of the course of phenomena combined with explanations relating to more or less isolated groups. The list of great names, including Kelvin, Maxwell, Helmholtz, that have been associated with the employment of the principle for the elucidation of the relations of deep-seated dynamical phenomena, is a strong guarantee that we shall do well by making the most of this clue.

Are we, then, justified in treating the material molecule, so far as revealed by the spectroscope, as a dynamical system coming under this specification? Its intrinsic energy is certainly permanent and not subject to dissipation; otherwise the molecule would gradually fade out of existence. The extreme precision and regularity of detail in the spectrum shows that the vibrations which produce it are exactly synchronous, whatever be their amplitude, and in so far resemble the vibrations of small amplitude in material systems. As all indications point to the molecule being a system in a state of intrinsic motion, like a vortex ring, or a stellar system in astronomy, we must consider these radiating vibrations to take place around a steady state of motion which does not itself radiate, not around a state of rest. Now, not the least of the advantages possessed by the action principle, as a foundation for theoretical physics, is the fact that its statement can be adapted to systems involving in their constitution permanent steady motions of this kind in such a way that only the variable motions superposed on them come into consideration. The possibilities as regards physical correlation of thus introducing permanent motional states as well as permanent structure into the constitution of our dynamical systems have long been emphasised by Lord Kelvin; the effective adaptation of abstract dynamics to such systems was made independently by Kelvin and Routh about 1877; the more recent exposition of the theory by Helmholtz has directed general attention to what is undoubtedly the most significant extension of dynamical analysis which has taken place since the time of Lagrange.

Returning to the molecules, it is now verified that the action principle forms a valid foundation throughout electrodynamics and optics; the introduction of the æther into the system has not affected its application. It is, therefore, a reasonable hypothesis that the principle forms an allowable foundation for the dynamical analysis of the radiant vibrations in the system formed by a single molecule and surrounding æther; and the knowledge which is now accumulating, both of the orderly grouping of the lines of the spectrum and of the modifications impressed on these lines by a magnetic field or by the density of the matter immediately surrounding the vibrating molecule, can hardly fail to be fruitful for the dynamical analysis of its constitution. But let it be repeated that this analysis would be complete when a formula for the dynamical energy of the molecule is obtained, and would go no deeper. Starting from our definitely limited definition of the nature of a dynamical system, the problem is merely to correlate the observed relations of the periods of vibration in a molecule when it has come into a steady state as regards constitution, and is not under the influence of intimate encounter with other molecules.

It may be recalled incidentally that the generalised Maxwell-Boltzmann principle of the equable distribution of the acquired store of kinetic energy of the molecule among its various possible independent types of motion is based directly on the validity of the action principle for its dynamics. In the demonstrations usually offered the molecule is considered to have no permanent or constitutive energy of internal motion. It can, however, be shown, by use of the generalisation aforesaid of the action principle, that no discrepancy will arise on that account. Such intrinsic kinetic energy virtually adds on to the potential energy of the system, and the remaining or acquired part of the kinetic energy of the molecule may be made the subject of the same train of reasoning as before.

Let us now return to the general question whether our definition of a dynamical system may not be too wide. As a case in point, the single principle of action has been shown to provide a definite and sufficient basis for electro-dynamics; yet when, for example, one armature of an electric motor pulls the other after it without material contact, and so transmits mechanical power, no connection between them is indicated by the principle, such as could by virtue of internal stress transmit the pull. The essential feature of the transmission of a pull by stress across a medium is that each element of volume of the medium acts by itself, independently of the other elements. The stress excited in any element depends on the strain or other displacement occurring in that element alone; and the mechanical effect that is transmitted is considered as an extraneous force applied at one place in the medium, and passed on from element to element through these internal pressures and tractions until it reaches another place. We have, however, to consider two atomic electric charges as being themselves some kind of strain configurations in the æther; each of them already involves an atmosphere of strain in the surrounding æther which is part of its essence, and cannot be considered apart from it; each of them essentially pervades the entire space, though on account of its invariable character we consider it as a unit. Thus we appear to be debarred from imagining the æther to act as an elastic connection which is merely the agent of transmission of a pull from the one nucleus to the other, because there are already stresses belonging to and constituting an intrinsic part of the terminal electrons, which are distributed all along the medium. Our action criterion of a dynamical system, in fact, allows us to reason about an electron as a single thing, notwithstanding that its field of energy is spread over the whole medium; it is only in material solid bodies, and in problems in which the actual sphere of physical action of the molecule is small compared with the smallest element of volume that our analysis considers, that the familiar idea of transmission of force by simple stress can apply. Whatever view may ultimately commend itself, this question is one that urgently demands decision. A very large amount of effort has been expended by Maxwell, Helmholtz, Heaviside, Hertz, and other authorities in the attempt to express the mechanical phenomena of electrical action in terms of a transmitting stress. The analytical results up to a certain point have been promising, most strikingly so at the beginning, when Maxwell established the mathematical validity of the way in which Faraday was accustomed to represent to himself the mechanical interactions across space in terms of a tension along the lines of force equilibrated by an equal pressure preventing their expansion sideways. According to the views here developed, that ideal is an impossible one. If this could be established to general satisfaction, the field of theoretical discussion would be much simplified.

Digitized by Google

This view that the atom of matter is, so far as regards physical actions, of the nature of a structure in the æther involving an atmosphere of æthereal strain all around it, not a small body, which exerts direct actions at a distance on other atoms according to extraneous laws of force, was practically foreign to the eighteenth century, when mathematical physics was modelled on the Newtonian astronomy and dominated by its splendid success. The scheme of material dynamics, as finally compactly systematised by Lagrange, had therefore no direct relation to such a view, although it has proved wide enough to include it. The remark has often been made that it is probably owing to Faraday's mathematical instinct, combined with his want of acquaintance with the existing analysis, that the modern theory of the æther obtained a start from the electric side. Through his teaching, and the weight of his authority, the notion of two electric currents exerting their mutual forces by means of an intervening medium, instead of by direct attraction across space, was at an early period firmly grasped in this country. In 1845 Lord Kelvin was already mathematically formulating, with most suggestive success, continuous elastic connections, by whose strain the fields of activity of electric currents or of electric distributions could be illustrated, while the exposition of Maxwell's interconnected scheme, in the earlier form in which it relied on concrete models of the electric action, goes back almost to 1860. Corresponding to the two physical ideals of isolated atoms exerting attraction at a distance, and atoms operating by atmospheres of æthereal strain, there are, as already indicated, two different developments of dynamical theory. The original Newtonian equations of motion determined the course of a system by expressing the rates at which the velocity of each of its small parts or elements is changing. This method is still fully applicable to those problems of gravitational astronomy in which dynamical explanation was first successful on a grand scale, the planets being treated as point masses, each subject to the gravitational attraction of the other bodies. But the more recent development of the dynamics of complex systems depends on the fact that analysis has been able to reduce within manageable limits the number of varying quantities whose course is to be explicitly traced, through taking advantage of those internal relations of the parts of the system that are invariable, either geometrically or dynamically. Thus, to take the simplest case, the dynamics of a solid body can be confined to a discussion of its three components of translation and its three components of rotation, instead of the motion of each element of its mass. With the number of independent co-ordinates thus diminished, when the initial state of the motion is specified, the subsequent course of the complete system can be traced; but the course of the changes in any part of it can only be treated in relation to the motion of the system as a whole. It is just this mode of treatment of a system as a whole that is the main characteristic of modern physical analysis. The way in which Maxwell analysed the interactions of a system of linear electric currents, previously treated as if each were made up of small independent pieces or elements, and accumulated the evidence that they formed a single dynamical system, is a trenchant example. The interactions of vortices in fluid form a very similar problem, which is of special note in that the constitution of the system is there completely known in advance, so that the two modes of dynamical exposition can be compared. In this case the older method forms independent equations for the motion of each material element of the fluid, and so requires the introduction of the stress—here the fluid pressure—by which dynamical effect it passed on to it from the surrounding elements: it corresponds to a method of contact action. But Helmholtz opened up new ground in the abstract dynamics of continuous media when he recognised (after Stokes) that if the distribution of the velocity of spin at those places in the fluid where the motion is vortical be assigned, the motion in every part of the fluid is therein kinematically involved. This, combined with the theorem of Lagrange and Cauchy—that the spin is always confined to the same portions of the fluid—formed a starting-point for his theory of vortices, which showed how the subsequent course of the motion can be ascertained without consideration of pressure or other stress.

The recognition of the permanent state of motion constituting a vortex ring as a determining agent as regards the future course of the system was, in fact, justly considered by Helmholtz as one of his greatest achievements. The principle had entirely eluded the attention of Lagrange and Cauchy and Stokes, who were the pioneers in this fundamental branch of dynamics, and had virtually prepared all the necessary analytical material for Helmholtz's use. The main import of this advance lay, not in the assistance which it afforded to the development of the complete solution of special problems in fluid motion, but in the fact that it constituted the discovery of the types of permanent motion of the system, which could combine and interact with each other without losing their individuality, though each of them pervaded the whole field. (We may compare G. W. Hill's more recent introduction of the idea of permanent orbits into physical astronomy.) This rendered possible an entirely new mode of treatment; and mathematicians who were accustomed, as in astronomy, to aim directly at the determination of all the details of the special case of motion, were occasionally slow to apprehend the advantages of a procedure which stopped at formulating a description of the nature of the interaction between various typical groups of motions into which the whole disturbance could be resolved.

The new train of ideas introduced into physics by Faraday was thus consolidated and emphasised by Helmholtz's investigations of 1858 in the special domain of hydro-dynamics. In illustration let us consider the fluid medium to be pervaded by permanent vortices circulating round solid rings as cores: the older method of analysis would form equations of motion for each element of the fluid, involving the fluid pressure, and by their integration would determine the distribution of pressure on each solid ring, and thence the way it moves. This method is hardly feasible even in the simplest cases. The natural plan is to make use of existing simplifications by regarding each vortex as a permanent reality, and directly attacking the problem of its interactions with the other vortices. The energy of the fluid arising from the vortex motion can be expressed in terms of the positions and strengths of the vortices alone; and then the principle of action, in the generalised form which includes steady motional configurations as well as constant material configurations, affords a method of deducing the motions of the cores and the interactions between them. If the cores are thin, they, in fact, interact mechanically, as Lord Kelvin and Kirchhoff proved, in the same manner as linear electric currents would do; though the impulse thence derived towards a direct hydro-kinetic explanation of electromagnetics was damped by the fact that repulsion and attraction have to be interchanged in the analogy. The conception of vortices, once it has been arrived at, forms the natural physical basis of investigation, although the older method of determining a distribution of pressure stress throughout the fluid and examining how it affects the cores is still possible; that stress, however, is not simply transmitted, as it has to maintain the changes of velocity of the various portions of the fluid. But if the vortices have no solid cores, we are at a loss to know where even this pressure can be considered as applied to them; if we follow up the stress, we lose the vortex; yet a fluid vortex can nevertheless illustrate an atom of matter, and we can consider such atoms as exerting mutual forces, only these forces cannot be considered as transmitted through the agency of fluid pressure. The reason is that the vortex cannot now be identified with a mere core bounded by a definite surface, but is essentially a configuration of motion extending throughout the medium.

Thus we are again in face of the fundamental question whether all attempts to represent the mechanical interactions of electro-dynamic systems, as transmitted from point to point by means of simple stress, are not doomed to failure; whether they do not, in fact, introduce unnecessary and insurmountable difficulty into the theory. The idea of identifying an atom with a state of strain or motion, pervading the region of the æther around its nucleus, appears to demand wider views as to what constitutes dynamical transmission. The idea that any small portion of the primordial medium can be isolated, by merely introducing tractions acting over its surface and transmitted from the surrounding parts, is no longer appropriate or consistent: a part of the dynamical disturbance in that element of the medium is on this hypothesis already classified as belonging to, and carried along with, atoms that are outside it but in its neighbourhood—and this part must not be counted twice over. The law of Poynting relating to the paths of the transmission of energy is known to hold in its simple form only when the electric charges or currents are in a steady state; when they are changing their positions or configurations their own fields of intrinsic energy are carried along with them.

It is not surprising, considering the previous British familiarity with this order of ideas, that the significance for general physics of Helmholtz's doctrine of vortices was eagerly developed in this country, in the form in which it became embodied through Lord Kelvin's famous illustration of the constitution of the matter, as consisting of atoms with separate existence and mutual interactions. This vortex-atom theory has been a main source of physical suggestion because it presents, on a simple basis, a dynamical picture of an ideal material system, atomically constituted, which could go on automatically without extraneous support. The value of such a picture may be held to lie, not in any supposition that this is the mechanism of the actual world laid bare, but in the vivid illustration it affords of the fundamental postulate of physical science, that mechanical phenomena are not parts of a scheme too involved for us to explore, but rather present themselves in definite and consistent correlations, which we are able to disentangle and apprehend with continually increasing precision.

It would be an interesting question to trace the origin of our preference for a theory of transmission of physical action over one of direct action at a distance. It may be held that it rests on the same order of ideas as supplies our conception of force; that the notion of effort which we associate with change of the motion of a body involves the idea of a mechanical connection

Digitized by Google

through which that effort is applied. The mere idea of a transmitting medium would then be no more an ultimate foundation for physical explanation than that of force itself. Our choice between direct distance action and mediate transmission would thus be dictated by the relative simplicity and coherence of the accounts they give of the phenomena; this is, in fact, the basis on which Maxwell's theory had to be judged until Hertz detected the actual working of the medium. Instantaneous transmission is, to all intents, action at a distance, except in so far as the law of action may be more easily formulated in terms of the medium than in a direct geometrical statement.

In connection with these questions it may be permitted to refer to the eloquent and weighty address recently delivered by M. Poincaré to the International Congress of Physics. M. Poincaré accepts the principle of least action as a reliable basis for the formulation of physical theory, but he imposes the condition that the results must satisfy the Newtonian law of equality of action and reaction between each pair of bodies concerned, considered by themselves; this, however, he would allow to be satisfied indirectly if the effects could be traced across the intervening æther by stress, so that the tractions on the two sides of each ideal interface are equal and opposite. (*Cf.* also Hertz on the electromagnetic equations, § 12, *Wied. Ann.*, 1890. The problem of merely replacing a system of forces by a statical stress is widely indeterminate, and therefore by itself unreal; the actual question is whether any such representation can be co-ordinated with existing dynamics.) As above argued, this view appears to exclude *ab initio* all atomic theories of the general type of vortex atoms, in which the energy of the atom is distributed throughout the medium instead of being concentrated in a nucleus; and this remark seems to go to the root of the question. On the other hand, the position here asserted is that recent dynamical developments have permitted the extension of the principle of action to systems involving permanent motions, whethether obvious or latent, as part of their constitution; that on this wider basis the atom may itself involve a state of steady disturbance extending through the medium, instead of being only a local structure acting by push and pull. The possibilities of dynamical explanation are thus enlarged. The most definite type of model yet imagined of the physical interaction of atoms through the æther is, perhaps, that which takes the æther to be a rotationally elastic medium, after the manner of MacCullagh and Rankine, and makes the ultimate atom include the nucleus of a permanent rotational strain-configuration, which as a whole may be called an electron. The question how far this is a legitimate and effective model stands by itself, apart from the dynamics which it illustrates; like all representations, it can only cover a limited ground. For instance, it cannot claim to include the internal structure of the nucleus of an atom or even of an electron; for purposes of physical theory that problem can be put aside, it may even be treated as inscrutable. All that is needed is a postulate of free mobility of this nucleus through the æther. This is definitely hypothetical, but it is not an unreasonable postulate because a rotational æther has the properties of a perfect fluid medium except where differentially rotational motions are concerned, and so would not react on the motion of any structure moving through it except after the manner of an apparent change of inertia. It thus seems possible to hold that such a model forms an allowable representation of the dynamical activity of the æther, as distinguished from the complete constitution of the material nuclei between which that medium establishes connection.

At any rate, models of this nature have certainly been most helpful in Maxwell's hands towards the effective intuitive grasp of a scheme of relations as a whole, which might have proved too complex for abstract unravelment in detail. When a physical model of concealed dynamical processes has served this kind of purpose, when its content has been explored and estimated, and has become familiar through the introduction of new terms and ideas, then the ladder by which we have ascended may be kicked away, and the scheme of relations which the model embodied can stand forth in severely abstract form. Indeed, many of the most fruitful branches of abstract mathematical analysis itself have owed their start in this way to concrete physical conceptions. This gradual transition into abstract statement of physical relations, in fact, amounts to retaining the essentials of our working models while eliminating the accidental elements involved in them; elements of the latter kind must always be present, because otherwise the model would be identical with the thing which it represents, whereas we cannot expect to mentally grasp all aspects of the content of even the simplest phenomena. Yet the abstract standpoint is always attained through the concrete; and for purposes of instruction such models, properly guarded, do not, perhaps, ever lose their value; they are just as legitimate aids as geometrical diagrams, and they have the same kind of limitations. In Maxwell's words, "for the sake of persons of these different types scientific truth should be presented in different forms, and should be regarded as equally scientific whether it appear in the robust form and the vivid colouring of a physical illustration, or in the tenuity and paleness of a symbolical expression." The other side of the picture, the necessary incompleteness of even our legitimate images and modes of representation, comes out in the despairing opinion of Young ("Chromatics," 1817), at a time when his faith in the undulatory theory of light had been eclipsed by Malus's discovery of the phenomena of polarisation by reflection, that this difficulty "will probably long remain to mortify the vanity of an ambitious philosophy, completely unresolved by any theory": not many years afterwards the mystery was solved by Fresnel.

This process of removing the intellectual scaffolding by which our knowledge is reached, and preserving only the final formulæ which express the correlations of the directly observable things, may, moreover, readily be pushed too far. It asserts the conception that the universe is like an enclosed clock that is wound up to go, and that accordingly we can observe that it is going, and can see some of its more superficial movements, but not much of them; that thus, by patient observation and use of analogy, we can compile, in merely tabular form, information as to the manner in which it works and is likely to go on working, at any rate for some time to come; but that any attempt to probe the underlying connection is illusory or illegitimate. As a theoretical precept this is admirable. It minimises the danger of our ignoring or forgetting the limitations of human faculty, which can only utilise the imperfect representations that the external world impresses on our senses. On the other hand, such a reminder has rarely been required by the master minds of modern science, from Descartes and Newton onwards, whatever their theories may have been. Its danger as a dogma lies in its application. Who is to decide, without risk or error, what is essential fact and what is intellectual scaffolding? To which class does the atomic theory of matter belong? That is, indeed, one of the intangible things which it is suggested may be thrown overboard in sorting out and classifying our scientific possessions. Is the mental idea or image, which suggests, and alone can suggest, the experiment that adds to our concrete knowledge less real than the bare phenomenal uniformity which it has revealed? Is it not, perhaps, more real in that the uniformities might not have been there in the absence of the mind to perceive them?

No time is now left for review of the methods of molecular dynamics. Here our knowledge is entirely confined to steady states of the molecular system: it is purely statical. In ordinary statics and the dynamics of undisturbed steady notions, the form of the energy function is the sufficient basis of the whole subject. This method is extended to thermodynamics by making use of the mechanically available energy of Rankine and Kelvin, which is a function of the bodily configuration and chemical constitution and temperature of the system, whose value cannot under any circumstances spontaneously increase, while it will diminish in any operation which is not reversible. In the statics of systems in equilibrium or in steady motion, this method of energy is a particular case of the method of action; but in its extension to thermal statics it is made to include chemical as well as configurational changes, and a new point appears to arise. Whether we do or do not take it to be possible to trace the application of the principle of action throughout the process of chemical combination of two molecules, we certainly here postulate that the static case of that principle, which applies to steady systems, can be extended across chemical combinations. The question is suggested whether extension would also be valid to transformations which involve vital processes. This seems to be still considered an open question by the best authorities. If it be decided in the negative, a distinction is involved between vital and merely chemical processes.

It is now taken as established that vital activity cannot create energy, at any rate in the long run, which is all that can from the nature of the case to be tested. It seems not unreasonable to follow the analogy of chemical actions, and assert that it cannot in the long run increase the mechanical availability of energy—that is, considering the organism as an apparatus for transforming energy without being itself in the long run changed. But we cannot establish a Carnot cycle for a portion of an organism, nor can we do so for a limited period of time; there might be creation of availability accompanied by changes in the organism itself, but compensated by destruction and the inverse changes a long time afterwards. This amounts to asserting that where, as in a vital system or even in a simple molecular combination, we are unable to trace or even assert complete dynamical sequence, exact thermodynamic statements should be mainly confined to the activity of the existing organism as a whole; it may transform inorganic material without change of energy and without gain of availability, although any such statements would be inappropriate and unmeaning as regards the details of the processes that take place inside the organism itself.

In any case it would appear that there is small chance of reducing these questions to direct dynamics; we should rather regard Carnot's principle, which includes the law of uniformity of temperature, and is the basis of the whole theory, as a pro-

Digitized by Google

perty of statistical type confined to stable or permanent aggregations of matter. Thus no dynamical proof from molecular considerations could be regarded as valid unless it explicitly restricted the argument to permanent systems; yet the conditions of permanency are unknown except in the simpler cases. The only mode of discussion that is yet possible is the method of dynamical statistics of molecules introduced by Maxwell. Now, statistics is a method of arrangement rather than of demonstration. Every statistical argument requires to be verified by comparisons with the facts, because it is of the essence of this method to take things as fortuitously distributed except in so far as we know the contrary, and we simply may not know essential facts to the contrary. For example, if the interaction of the æther or other cause produces no influence to the contrary, the presumption would be that the kinetic energy acquired by a molecule is, on the average, equally distributed among its various independent modes of motion, whether vibrational or translational. Assuming this type of distribution to be once established in a gaseous system, the dynamics of Boltzmann and Maxwell show that it must be permanent. But its assumption in the first instance is a result rather of the absence than of the presence of knowledge of the circumstances, and can be accepted only so far as it agrees with the facts; our knowledge of the facts of specific heat shows that it must be restricted to modes of motion that are homologous. In the words of Maxwell, when he first discovered in 1860, to his great surprise, that in a system of colliding rigid atoms the energy would always be equally divided between translatory and rotatory motions, it is only necessary to assume, in order to evade this unwelcome conclusion, that "something essential to the complete statement of the physical theory of molecular encounters must have hitherto escaped us."

Our survey thus tends to the result that, as regards the simple and uniform phenomena which involve activity of finite regions of the universal æther, theoretical physics can lay claim to constructive functions, and can build up a definite scheme; but in the domain of matter the most that it can do is to accept the existence of such permanent molecular systems as present themselves to our notice, and fit together an outline plan of the more general and universal features in their activity. Our well-founded belief in the rationality of natural processes asserts the possibility of this, while admitting that the intimate details of atomic constitution are beyond our scrutiny and provide plenty of room for processes that transcend finite dynamical correlation.

ABERDEEN ELECTRICITY ACCOUNTS.

We have pleasure in giving an abstract of the Aberdeen electric lighting accounts for the year ending July 31, 1900. A comparison between the figures given and those for the previous year tells its own tale; the progress shown reflects great credit upon the Corporation and the enterprise of their able engineer, Mr. J. Alex. Bell, who, taking into consideration the extensive tramway scheme undertaken by the Corporation, must have accomplished an immense amount of work during the financial year ending July 31, 1900. In connection with the figures given it will be noted that under expenditure accounts an item of £169 is included in the £415. 13s. 10d. for mains and service repairs. This £169, we understand, is for outlay for men's time and material in carboning and attending to the harbour lamps, and therefore should not be included in the work's costs. The price charged the Tramways Committee for current is also entered up. The arrangement made was that the department should supply the Tramways Committee with current at cost price, including interest and sinking fund. The following particulars, not included in the accounts, may be of interest: Capacity of dynamos installed = 1156kw.; maximum load = 765kw.; Number of 33-watt lamps connected during year: arcs, 1,830; incandescents, 9,529; motors, 18,709—total connections for year, 30,068. Total number of motors now on mains, 63; total horse-power of motors coupled to mains, 192·58; grand total of consumers now coupled in 33-watt lamps, 71,995. The maximum load includes tramway supply, but the lamps, motors, etc., connected does not include tramway data. These figures constitute a record for Aberdeen, so far as connections and output are concerned, and there is every indication that next year will be quite as satisfactory. One point in favour of the supply is, perhaps, that the price of gas has been raised 2d. per 1,000 cubic feet, while the Electric Lighting Committee have decided to keep the price of electrical energy per unit at the present figure.

Quantity not accounted for			130,560

Number of public lamps—76 arc, 80 incandescent.

SOUTH SHIELDS ELECTRICITY WORKS.

The accounts of the South Shields electricity works, just issued, show a total expenditure on capital account to March 31, 1900, of £88,686. 14s. The revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are given herewith:

Revenue Account.

Dr.	Generation of Electricity.	£	s.	d.
Coal or other fuel, including dues, carriage, unloading, storing, and all expenses of placing the same on the works	£922 14 10			
Oil, waste, water, and engine-room stores	229 0 0			
Wages at generating stations	794 0 7

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Hampstead.—The Vestry invite tenders for various plant for their central station, Lithos-road, Finchley-road. Tenders by Sept. 27.

Piatra Neamtz (Roumania).—The Municipality invite tenders for the lighting of the town by electricity for 30 years by Nov. 2 (concession).

Plumstead.—The Vestry invite tenders for the supply and erection of various plant and machinery for electricity works. Tenders by Sept. 19.

Perth.—The Commissioners invite tenders for meters (direct-current) and cut-outs. Tenders by Sept. 15. Details in our advertisement columns.

Nottingham.—The City Council invites tenders for the construction and erection of a new power station at St. Ann's Well-road. Tenders by Sept. 21.

Philippopolis (Bulgaria).—The Town Council invite tenders for erection and working of electric lighting and working of tramways. Tenders by Nov. 4 (concession).

Hackney.—The Electric Lighting Committee of the Vestry invite tenders for electricity supply mains. Tenders by Oct. 3. Details in our advertisement columns.

Melton (Suffolk).—The Visiting Committee of the Suffolk County Lunatic Asylum invite tenders for wiring and fittings. Tenders by Oct. 5. Details in our advertisement columns.

Horton (Surrey).—The Asylums Committee of the London County Council invite tenders for the installation of boilers, engines, dynamos, etc., at the Horton Estate, Epsom, Surrey. Tenders by Sept. 22.

Whitehaven.—The Water and Lighting Committee of the Corporation invite tenders for the supply and erection of a switchboard at their electric lighting station. Tenders by Oct. 13. Details in our advertisement columns.

Fulham.—The Vestry invite tenders for the supply and erection of plant for unloading and storing coal at their electric lighting works, Townmead-road, Fulham. Tenders by Sept. 25. Details in our advertisement columns.

Hull.—The Electric Lighting Committee invite tenders for steam and water pipes, feed pump, water softener, etc., at their Sculcoates-lane generating station. Tenders by Sept. 27. Full details in our advertisement columns.

Tunbridge Wells.—The Corporation invite tenders for the supply and delivery of high and low tension cables. Specification and full particulars can be obtained from Mr. Horace Boot, borough electrical engineer. Tenders by Sept. 20.

Dublin.—The Corporation invite tenders for electric motors and pumps for Ringsend drainage works. Specifications may be obtained at the office of the consulting engineer, Mr. Chatterton, 6, The Sanctuary, Westminster. Tenders by Oct. 3.

Manchester.—The Tramways Committee invite tenders for the supply of two steel boilers for heating purposes, cast-iron pipes, etc.; rubber rings, bolts and nuts, steel stanchions, etc.; 100 car trucks. Tenders by 18th inst. Details in our advertisement columns.

Limerick.—The Town Council invite tenders for erection and completion of an electric generating station building at Frederick-street, Limerick. Drawings and specification may be seen at the office of Mr. J. J. Peacocke, B.E., city surveyor, Town Hall, Limerick. Tenders by Oct. 4.

Walthamstow.—The Council invite tenders for the supply, delivery, and erection of electric lighting plant and apparatus, consisting of gas plant, gas-engines, dynamos, switchboard, booster, balancer, and measuring instruments. Tenders by Sept. 25. Details in our advertisement columns.

Dundalk.—Tenders are invited by the Urban District Council for a transfer of their electric lighting order for the purpose of supplying electricity for public and private lighting and energy for manufacturing purposes within the urban district of Dundalk. Tenders by Sept. 18. Details in our advertisement columns.

Eastbourne.—The Corporation invite tenders for the supply and erection of a water-tube boiler, with fittings, feed pump, etc., a 400-kw. steam alternator, with exciter (vertical enclosed high-speed engine), and main switchboard and connections. Tenders by Oct. 4. Particulars appear in our advertisement columns.

Devonport.—The Corporation invite tenders for supply and erection of (Part 1) two vertical engines; (2) two 300 kw. generators, balancer, battery, booster, and motor; (3) switchboard for electric lighting and traction; storage battery and travelling crane (10 ton). Tenders by Sept. 26. Details in our advertisement columns.

London, E.C.—The Commissioners of H.M. Works and Public Buildings invite tenders for the enlargement of Block E of the telegraph factory at Mount Pleasant, E.C. Drawings, specification, and a copy of the conditions and form of contract may be seen on application to Mr. J. Wager, at H.M. Office of Works, etc. Tenders by Sept. 18.

Middleton and Castleton (Lancs.).—The British Electric Traction Company invite tenders for the construction of light railways in Middleton and Castleton, near Manchester (length in all about seven miles). Drawings may be seen at the offices of the Engineer to the Company, Lennox House, Norfolk-street, Strand. Tenders by 15th inst.

Dundee.—The Dundee Gas Commissioners invite tenders for: (1) overhead travelling crane; (2) economiser; to be supplied and erected at the electric lighting station, Dundee. Specifications, plans, and forms of tender may be had on application to Mr. Walter H. Tittensor, city electrical engineer, Dunhope-crescent-road, Dundee. Tenders by 26th inst.

London, S.W.—The London County Council invite tenders for the supply within 12 weeks of the order being given of the mains required in connection with the electric light installation for the Victoria embankment and Westminster Bridge. Particulars may be obtained at the Engineer's Department, County Hall, Spring-gardens, S.W. Tenders by 24th inst.

Sunderland.—The Corporation invite tenders for the supply of (A) triple-expansion, high-speed, direct-current steam dynamos; (B) Lancashire boilers; (C) feed pumps. The several specifications and forms of tender can be obtained on application to the borough electrical engineer, Mr. J. F. C. Snell, A.M.I.C.E., Dunning-street, Sunderland. Tenders by 21st inst.

Brighton.—The Council invite tenders for the supply and delivery of 2,000 tons of steel girder tramrails, 78 tons of steel fishplates, 90 tons of steel joists. Specifications and form of tender and all necessary information may be obtained on application at the office of Mr. Thos. B. Holliday, tramways engineer, Town Hall, Brighton. Tenders by Oct. 1.

Aberdeen.—The Electric Lighting Committee invite tenders for supply of (1) two 200-kw. direct-coupled continuous-current generators and one 120-kw. balancing set; (2) one 420-kw. direct-coupled continuous-current generator. Specification and form of tender can be obtained from Mr. J. Alex. Bell, city electrical engineer, Cotton-street, Aberdeen. Tenders by Sept. 29.

Dublin.—The Electric Lighting Committee of the Corporation invite tenders for the supply and laying of electricity supply mains and accessories. Specifications and form of tender may be inspected at the office of the city engineer, Mr. Spencer Harty, M.I.C.E., City Hall, Dublin, and at the offices of Mr. R. Hammond,

Digitized by Google

consulting engineer to the Corporation, 64, Victoria-street, S.W. Tenders by Oct. 4.

Maxborough.—The Council invite tenders for the supply and erection of a Lancashire boiler; two 50-kw. steam dynamos, balancer and boosters, feed-water heater, and feed pump; switchboard and connections; storage battery; mains; a five-ton hand travelling crane; and for adapting public street lamps from gas to incandescent electric. Tenders by Sept. 15. Details in our advertisement columns.

Brighton.—The Corporation invite tenders for the supply and delivery of 25 electric motorcars. The work is divided into three sections, and contractors may tender in respect of all or any one or more of such sections—viz.: (Section 1) 25 electric motorcar bodies; (2) 25 electric motor trucks; (3) 25 electric motor electrical equipments. The specification and form of tender and all necessary information may be obtained on application at the office of the tramways engineer, Mr. Thos. B. Holliday, Town Hall, Brighton. Tenders by Oct. 1.

Blackpool.—The Tramway Committee invite tenders for the construction of a single and double line of tramways in Waterloo-road, Whitegate-drive, Raikes-road, Church-street, Abingdon-street, Talbot-road, and Central drive The respective lengths will be about one mile single and 2¼ miles double The contract will include the laying of rails, points, etc., excavating, concreting, paving, etc. The Corporation will provide all the materials. Drawings may be seen and specifications and bills of quantities obtained on application to Mr. J. Wolstenholme, borough engineer, Town Hall, Blackpool. Tenders by 17th inst.

RESULTS OF TENDERS.

City of London Union.—The Board have accepted the tender of Messrs. Newsome, Pincking, and Walton, of 1, Crutched-friars, at £430, for lighting the offices by electricity.

Rochdale.—The General Purposes Committee have accepted the tender of Mr. G. L. Adamson, Ohm Works, Rochdale, for the wiring and fittings required in connection with the electric lighting of the town hall.

Middlesbrough.—The Electric Lighting Committee have accepted the tender of Messrs. Tattersall and Smith, Middlesbrough, subject to the confirmation of the Council, for the wiring of the municipal electricity works.

Portsmouth.—The Tramway Committee have accepted the following tenders with regard to the building and plant for the new power station: Messrs. Dick Kerr, and Co., plant, £29,656; Mr. J. W. Perkins, building, £10,515.

Nuneaton.—The Hart Accumulator Company, Limited, Marshgate-lane, Stratford, London, E, have secured the contract for the storage battery required by the Nuneaton and Chilvers Coton Urban District Council for their electric lighting extension.

Cardiff.—The Electrical and Lighting Committee have accepted the tender of Messrs. Lace and Sons, of Cardiff, at £1,379, for supplying a quantity of steam pipes and a pump at the electric light works, and that of the British Insulated Wire Company, at £607. 11s. 5d., for high-tension cables.

Bradford.—The Council have accepted the following tenders: Messrs. Humphries and Moulson, Bradford, excavators', masons' work, etc., £4,780; Mr. S. Rushworth, Bradford, plumbers' work, £540; Messrs. Bradley and Krischke, Bradford, concretors' and plasterers' work, £435; Messrs. Mavor and Coulson, Glasgow, 12 months' supply of motors at following prices: 4½-h.p. £39. 10s. each, 7-h.p. £48 each, 10-h.p. £59 each.

Nuneaton.—The Council have accepted the following tenders: Messrs. Babcock and Wilcox, new boilers, about £1,060: Hart Accumulator Company, accumulators, £1,063; Mr. E. Carrington, switchboard, £391; Messrs. Clarke, Chapman, and Co., exchanging existing armature, £66; Nuneaton Engineering Company, travelling crane, £120. The Council will also purchase testing instruments at a cost of about £50, a new engine and dynamo at a cost of about £1,900, and an economiser at a cost of about £320.

Aberdeen.—The Tramways Committee have received the following tenders for steel poles, bases, and brackets: Macartney, McElroy, and Co., 53, Victoria-street, Westminster, S.W. (accepted); R. W. Blackwell and Co., London; Walsall Electric Company, Walsall; McDowall, Steven, and Co., Glasgow; Lowdon Bros. and Co., Dundee; J. Russell and Sons, Limited, Wednesbury. The same committee have also accepted the tender of Messrs. M'Lellan, Glasgow (representing German manufacturers) for rails.

Darlington.—The Corporation have received the following tenders for the supply and delivery of arc lamp-posts and brackets in connection with the electric lighting of the borough:

Mackenzie Bros., Edinburgh Foundry, Slateford-road, Edinburgh (accepted)	£378	17	6
J. and A. Law, Glasgow	428	15	0
Rowland, Carr, and Co., 6 and 8, Lime-street-square, London, E.C.	477	15	0
J. Allan and Son, Elmbank Foundry, Glasgow	485	12	6
T. E. Kershaw, Nuneaton	490	0	0
W. A. Baker and Co., Limited, Newport, Mon.	767	7	6
Maxim Electrical and Engineering Export Company, 65, 66, and 67, Gracechurch-street, London	1,181	5	0

Aberdeen.—The Electric Lighting Committee have received the following tenders: (1) Cables—British Insulated Wire Company, Limited, Prescot (accepted); Siemens Bros. and Co., Limited, 12, Queen Anne's-gate, Westminster, London, S.W.; Callender's Cable and Construction Company, Limited, 90, Cannon-street, London, E.C.; St. Helens Cable Company, Limited, Warrington; W. T. Henley's Telegraph Works Company, Limited, 27, Martin's-lane, Cannon-street, E.C.; W. T. Glover and Co., Limited, Trafford Park, Manchester; Western Electric Company, Limited, North Woolwich, London, E.; Telegraph Manufacturing Company. Limited, Helsby. (2) House main fuse boxes—A. Spark, 35, Summer-street, Aberdeen (accepted); Keighley Electrical Engineering Company, Limited, Keighley; Reason Manufacturing Company, Limited, Gloster-road, Brighton; Callender's Cable and Construction Company, 90, Cannon-street, E.C.: British Insulated Wire Company, Limited, Prescot; General Electric Company, Limited, London. (3) Meters—S. Z. de Ferranti, Limited, Hollinwood (accepted); Chamberlain and Hookham, Birmingham; General Electric Company, Limited, London; Schattner Electric Meter Company, Timberhill, Norwich; Reason Manufacturing Company, Limited, Gloster-road, Brighton; Electrical Company, Limited, Dashwood House, New Broad-street, London, E C.

Hanley (Staffs).—The Corporation have received the following tenders for electric lighting works and plant. Accepted tenders: Hughes and Lancaster, Ruabon, Shone ejector chambers, £864; W. Williams, Etruria, Newcastle road to Etruria intercepting sewer £480 (conditionally), Keeling's-road to Prime-street intercepting sewer £870 (conditionally); T. Godwin, Hanley, Trent Bridge widening, abutment, £235.

BUSINESS NOTES.

TRACTION.

Cheltenham.—We understand that the proposed electric tramway to the top of Cleeve Hill is to be commenced next month.

Crewe.—The Town Council have endorsed the recommendation of the Electric Light Committee to provide a scheme of electric tramways.

Aberdeen.—The Corporation have adopted a revised and increased scale of wages for tramway conductors, drivers, and inspectors.

Louth.—The County Council have received an order in Council extending the time for the completion of the Dundalk electric tramway system.

Johnstone.—It is reported that the Paisley Town Council will probably apply for an order to provide tramways for that burgh and to connect with Johnstone.

Brankseme.—The work of construction of the electric tramway was commenced in the Brankseme district on Aug. 13, and a considerable length has been laid along the western end of the Ashley-road.

Jungfrau Railway.—The works upon the Jungfraubahn have been at a standstill for some months. The expense of the undertaking, as the experts now declare, would be tenfold greater than was originally estimated.

Bradford.—The Town Council on Tuesday adopted the minutes of the Tramways Committee which included a resolution instructing the city surveyor to extend the Whetley-hill tramway as a double line to the end of Godwin-street.

Aspull.—The Wigan Corporation Electric Light and Tramway Committee propose to extend the tramway system from Wigan to Aspull. Plans and written particulars are about to be forwarded to the District Council for consideration.

Bowness.—A meeting of the inhabitants was held on Friday night with the object of showing opposition to the tramway proposals. A resolution condemnatory of the scheme was adopted, and a committee appointed to formulate opposition.

Darwen.—At a recent meeting of the inhabitants of Hoddlesden and district a resolution was passed in favour of trams running between Darwen and Hoddlesden, and a deputation will be sent to the Town Council urging them to push the matter forward.

Kirkcaldy.—The Town Council on the 10th inst. adopted the recommendation of the Tramway and Electric Lighting Committee to widen parts of the High-street so that the tramcars could be run both ways. The cost of purchasing property, etc., for improvement, as estimated by Prof. Kennedy, is £20,800.

Roundhay.—The new electric launch for Roundhay Park lake, which is being built to the order of the Leeds Corporation, is expected to be ready for launching on the Thames about Monday next. The vessel, which will hold 45 passengers, will be named the "Mary Gordon," as a compliment to the present lady mayoress.

Queensbury.—At Monday's meeting of the District Council a letter was read from the Bradford Tramways Committee stating that the material for the construction of the tramways to Queensbury was on order, and that it was their intention to proceed with the work immediately. It was decided to advertise for tenders for the alterations at Priestly Hill.

North Woolwich.—The scheme for connecting North Woolwich and Ilford by means of an electric tramway was advanced another stage on Tuesday evening, when the foundation stone of the electric station at East Ham was laid. When the West Ham, East Ham, and Ilford schemes are completed the electric tramway area will cover upwards of 25 miles.

Leith.—The Town Council have appointed a Tramways Committee to consider the advisability of laying tramways within the borough, and also to consider and, under the direction of the Council, to deal with any question that may arise in connection with the tramways proposed to be laid within the borough by the South Lancashire Tramways Company.

Dublin and Lucan Electric Railway Co.—The traffic returns for the week ending Sept. 8, 1900, were £125, as compared with the week ending Sept. 1, 1900, of £104, showing an increase of £21. The total receipts (10 weeks to Sept. 8, 1900) are £1,181, as compared with the corresponding period of 1899 of £960, showing an increase of £221. (Received too late for classification.)

Stourbridge.—Trial trips have been made along the Kingswinford Electric Tramway during the last few days, and the opening of the line for public traffic will take place shortly. Some new cars for this and the connected branches have just been delivered at the Stourbridge goods Depôt, and they differ from those which have been running on the Dudley and Stourbridge line in being two-deckers.

Standish.—The Wigan Corporation Electric Light and Tramway Committee propose to run electric trams along Wigan-lane, past Boar's Head, and on to Standish, and also to Standish Lower Ground as far as the Royal Oak Inn. The Standish District Council, however, are not prepared, as the roads are at present circumstanced, to allow the Corporation to run electric trams in the Standish districts, but they would favour a proposal which included the widening of these roads.

Workington.—The minutes of a special committee meeting of the whole Council, adopted on Tuesday, contained a resolution refusing to entertain the proposition for granting a concession to Messrs. Dick, Kerr, and Co.'s combination for obtaining powers to construct an electric tramway between Whitehaven and Maryport, and to appoint representatives to attend a proposed conference among the Whitehaven, Maryport, and Workington authorities on the subject. The question was referred by the Council, in committee, to the committee already appointed to consider electric lighting.

York.—At the half-yearly meeting of the York Tramways Company last week, the chairman (Mr. Joseph Kincaid, M.I.C.E., Westminster) remarked that the Corporation had applied to the Board of Trade for power to acquire the undertaking by purchase. There was some advantage to the company in throwing upon the Corporation the onus of doing what was necessary to satisfy the requirements of the vehicular traffic, because the purchase of the tramways by the Corporation would involve a considerably higher figure under present prices of materials than it would last year or the year before. The report and accounts were adopted, and a dividend of 6 per cent. was declared.

Sheffield.—A double line of rails is to be laid on Penistone road from Owlerton Bridge to Burnell-road, instead of a single line as previously agreed. The committee being desirous of proceeding with the tramway along Shoreham-street at an early date, have expressed the opinion that the street should be paved with wood between the track and 18in. on either side. The city surveyor is to prepare plans to provide for emergency exits for the cars at Tinsley and Queen's-road car depôts. The Board of Trade have at last approved of the electric traction on the Abbeydale route and on the London-road route to Queen's-road. Half a dozen cars are being fitted with the "ever dry" seats as an experiment.

Accrington.—A very short time may witness the conversion of the Accrington tramways into electric cars of the latest and approved type. The Corporation will be asked to provide a complete equipment on the overhead system, including the cars, and the tramway company is to work the line for the remaining 6½ years of their lease, charging the present rental, and in addition a certain percentage in the way of interest upon the outlay entailed by the conversion from steam to electric traction, the company, of course, purchasing its electricity for motive power from the Corporation. The Corporation would then take over the present rolling-stock of the tramways company at a valuation.

Colchester.—The Mayor, Aldermen Sanders, Elwes, Wicks, Egerton-green, Paxman, Goody, and Butcher, and Councillors Marshall, Marriage, Benham, Egerton-Green, Barritt, Moore, Greenwood, Littlebury, Grimes, and Nash have been appointed as a special committee to prepare and submit a scheme for tramways, and to take all such proceedings as may be needful in connection therewith, and with the application for a provisional order if the Council adopt a scheme. It has also been decided that as soon as the committee are in a position to present a scheme the Mayor be desired to summon a meeting of the Council in accordance with the Board of Trade rules for the earliest possible date in order that the scheme may be considered.

Wigan.—The question of making a cash offer, etc., for the Wigan and District Tramways Company's undertaking has been deferred until the Routes' Committee has reported on the lines proposed to be constructed and worked by the Corporation. The Pemberton Urban District Council having desired that the gauge of the tramway from the market place to Adams' Bridge should be altered from 3ft. 6in. to 4ft. 8½in., which would enable the Wigan tramways to be connected directly with the projected system of the South Lancashire Tramways Company, the Corporation have replied that they do not intend to alter the gauge, the whole question having been carefully considered before the tramways now being constructed had been decided upon.

Dudley.—At the meeting of the Town Council on Tuesday it was stated in reply to whether any information had been received as to the starting of the trams to Netherton, that it was entirely a matter for the Board of Trade. The Electric Traction Company had sold the tramways to Netherton and Stourbridge to the Dudley, Stourbridge, and District Tramway Company. When Mr. Trotter inspected the wires and the electrical apparatus on behalf of the Board of Trade, he was content to allow the company to commence running, but it was part of the conditions that Colonel Yorke should inspect the permanent way, and the new company declined to work the lines until the other company could turn them over with the sanction of the Board of Trade.

Brighton.—The surveyor and Mr. Holliday are preparing an estimate, with plans, sections, and specifications, for laying the concrete bed, the tram rails, and wood paving blocks, in the several streets in which the tramways are to be constructed, the same to be divided into sections for separate districts. The specification for motorcars, prepared by Mr. Holliday for double-decked cars for the tramways, has been approved, and tenders have been invited for the supply of 25 cars in accordance therewith, with the option to the Corporation to order five additional cars of the same description at some later date at the same price. Specifications for the quantity of rails and fishplates required for the tramways (about 2,000 tons) have also been approved. The engineer and Mr. Holliday are about to prepare estimate of cost of levelling the land required for the car-shed, and of the cost of construction of the car-shed.

London United Tramways.—The company hope to start the service of electric cars between Hammersmith and Kew Bridge in about a month from the present date. Formal notices have been served upon local authorities this week by the London United Tramways Company, Limited, of their intention to apply to Parliament in the ensuing session for a great extension of their

Digitized by Google

authorised system of tramways. The scheme embraces the construction of over 60 miles of tramways in three counties—viz.: 23 miles in Surrey, 20 miles in Middlesex, and 20 miles in the County of London. The centre of the proposed extension will be the Broadway, Hammersmith, from which main lines with feeders will radiate in various directions. In the county of London the extensions will reach and serve the districts of St. Pancras, St. Marylebone, Paddington, Kensington, Fulham, Hammersmith, and Putney. In the county of Middlesex the extensions affect the parishes of Ealing, Brentford, Southall, Heston and Isleworth, Twickenham, Hampton, Teddington, Hanworth, Sunbury, and Hampton Wick. In the county of Surrey the places affected are Barnes, Richmond, Kingston, Malden and Coombe, Surbiton, Esher and the Dittons, and East Molesey.

Railway Concessions in Spain.—The Spanish Government has recently granted a number of railroad concessions for standard, narrow-gauge, and electric roads. Amongst them are a concession granted to the Sociedad Minera de Villaodrid, of Villaodrid, for a narrow-gauge railroad line from Puente Nuevo to the mining districts of Puerto Estrecho, in the north of Ripadeo. A large iron shed for storing ore is to be built in connection with this line. The Sociedad Ferrocarrilly Minas de Berga, of Berga, has a concession for a railroad between Olvan and Guardiola, to connect with the Manresa to Berga line; the latter, a narrow-gauge railroad, is 51 miles long, metre gauge, 11 engines, 19 passenger and 96 freight cars. A concession has been granted for an extensive net of electric railroads between Almeria, Benahadux, Rioja, and Tabernas. The Compania Vasco-Asturiana has a concession for the extension of its present system to Ujo and Trubia. A syndicate of Orense financiers has a concession for narrow-gauge railroads from Orense to the Portuguese frontier, passing over Barbadanes, Celanova Allaviz, Sandianes, Ginzo de Limia, Trasmovas, Coaledvo, Illadviz, Villara, and Verin. Considerable quantities of rolling-stock and material will be ordered abroad.—*Railway News.*

Sunderland.—About 25,000 passengers were carried on the Sunderland tramways on Saturday. The Royal Assent having been given to the Houghton and Sunderland Electric Tramways Bill, a start will be made at once with the preliminary work. The line will commence at Grangetown, on the southern boundary of Sunderland, and will pass through the populous colliery villages of Ryhope, Tunstall, New Silksworth, New Herrington, Philadelphia, Newbottle, Houghton-le-Spring, Hetton-le-Hole, and Easington-lane. There will also be branch lines, the total mileage being about 20, and the population of the district 60,000, exclusive of Sunderland. It is also proposed to extend the line across the Wear at Pensher to Workington and Usworth, affording communication with Newcastle. The overhead trolley system will be used, and it is proposed to carry goods by day and night in special trucks The various local bodies in the district have given their sanction to the scheme, which has been promoted by the United Kingdom Tramways, Light Railway, and Electrical Syndicate.

Electric Railways in London.—The correspondent of the *Daily Telegraph* wired from New York on Wednesday as follows: "According to Mr. Bernard M. Baruch, of the A. A. Houseman Company, Mr. Charles T. Yerkes has purchased the franchise and all the rights of the Charing Cross, Euston, and Hampstead Railroad, and has formed a syndicate of American capitalists to build a tunnel railroad under the streets from Charing Cross to Hampstead Heath; also an extension of two miles from Camden-road to Kentish Town. Mr. Yerkes's agents reported that the road, if built, promised good returns. Mr. Yerkes, on receiving the assurance that several friends in New York and Chicago would help him to finance the scheme, went to London and bought the company's rights. Mr. Baruch said that the 12,000 000dol needed to build the road would all be American capital. The road will probably have 10 stations and four tracks, two for express and two for local trains. Electricity will be the motive power. It is estimated that connecting railroads will bring the Charing Cross-Hampstead line within the reach of 150,000 persons." The *Daily Mail* says the news is possibly intended for consumption on the other side of the Atlantic, for it is well known in London railway and financial circles that Mr. Yerkes possesses no such rights as are here ascribed to him.

Maidstone.—Mr. Stephen Sellon has just issued his report with regard to the promotion of a scheme of electric trams for Maidstone. From a *résumé* which appeared in the *Kent County Standard* we gather that he examined six routes, all starting from High-street, which are defined as follows: (1) 1 mile 7 furlongs 5·50 chains to the Fountain Inn; (2) 5 furlongs 4 chains to the athletic ground; (3) 5 furlongs to the back of the Sessions House; (4) 6 furlongs 4·50 chains to Turkey Mill; (5) 1 mile 2 furlongs to the cemetery; (6) 7 furlongs 9 chains to Tovil—total length, 6 miles 2 furlongs 3 chains. The estimate for it all would be £40,721. A portion of this is allotted to the supply of wood paving, and also a double line in some parts; leaving out the double line, £1,016 would be saved in capital cost. Mr. Sellon quotes the width of certain streets in the towns where electric trams and light railways have been authorised. The narrowest points in these are: Gateshead, 18ft. 3in.; Coventry, 19ft. 6in; Ashton, 20ft. 2in.; Greenock, 18ft.; Croydon, 18ft.; Merthyr, 18ft. 6in.; Stourbridge, 16ft.; Dover (narrowest width of Snargate-street), 15ft. 4in., with a gauge of 3ft. 6in.; Reading, 18ft. 10in. The gross earning capacity of a system of tramways such as he suggests for Maidstone would be fairly represented, he thinks, by £7,200 per annum (liable to increase year by year). The working expenses should be about 50 per cent., which, after allowing for depreciation and repairs, would leave a profit of £2,900. On this he assumes a net profit for the first year of £457, after deducting interest on loan and contribution to sinking fund. He says, in conclusion, that he has taken a pessimistic view of the profits, and has taken a lower figure than is earned by the horse tramways in Chester, a town with a population about equal to that of Maidstone, and with only 2¼ miles of tramway, which does not in any way properly serve the town. He is also taking a gross earning capacity of some £3,000 per annum less than that of Dover.

Up to Date.—From an interview with the secretary of the Central London Railway Company, which recently appeared in the *Daily Chronicle*, we quote as follows: "Before the line was opened," he said, "we expected that on Sundays we should have practically no travellers. Happily our anticipations have not been realised, for we get crowds of people going to and from Hyde Park, Kew Gardens, Richmond, and other popular resorts. Of course, this may be merely a summer traffic, but we hope it will continue in the winter. As to a later and earlier service of trains, I don't think the general manager could arrange such conveniences just now, for every night the line from Shepherd's Bush to the Bank is thoroughly examined, the lifts are tested, the signal-boxes are inspected, and the 100 or more carriages are taken to the car-shed to be overhauled. We are, indeed, most careful to prevent any mishap. I saw some time ago the question raised as to what would happen if an accident occurred in the tunnel between two stations. The person who asked this forgot that the travellers in the train could get out from either end, and that there would be no danger so far as the electricity is concerned, for the current can be switched off between any particular section. There has been an enquiry as to the temperature of the railway. This remains steady at 55deg. This summer the Central London Railway has proved itself to be the coolest place in the metropolis. In the winter the temperature will be as in the summer, for the outer air does not affect the earth so low down as our tunnel, the depth, as you know, being an average of 60ft. In an attempt to make the line popular with people living at Acton, Ealing, and other districts beyond Shepherd's Bush, we erected sheds for the storing of cycles, and charge 2d. a machine. On the first morning we had from 15 to 20 cycles. Last Monday there were no fewer than 96. We have now decided to have a proper and a larger building for the convenience of cyclists. A faster train service is not possible yet. We are waiting for more rolling-stock, and when we get the carriages we shall run trains every three instead of every four minutes as now."

LIGHTING AND GENERAL.

Middlesbrough.—It is expected that the electric lighting will be started early in October.

Bradford.—The Electricity Committee intend to apply for borrowing powers amounting to £56,315 for extension purposes.

Alfreton.—The Town Council are promoting a scheme for an electric light installation, which, however, is not yet definitely settled.

Darlington.—It is reported that as soon as the electrical engineer has been appointed the work of wiring private houses will be proceeded with.

W. T. Glover and Co.—The preference share transfer books of this Company will be closed from the 17th inst. to the 29th inst., both inclusive, for the preparation of dividend warrants.

Hunsworth.—The District Council have decided to receive a deputation from the Northern Counties Electric Lighting Company at the next meeting with reference to their proposal to apply for a provisional order to supply electric light in the district.

Langton.—Mr. H. P. Boulnois has held an enquiry into the application of the Corporation for sanction to borrow £28,500 for purposes of electric lighting, and for approval of the use of certain land situate at the Corporation gasworks as a site for a generating station.

Douglas.—At a meeting of the Town Council on Wednesday the reason for the delay in the electric lighting scheme was enquired into. The Chairman of the committee replied that they had been waiting in expectation of the tramway concern being offered for sale by the liquidator. He promised that the committee would have an early meeting and submit a report.

Cleethorpes.—At the monthly meeting of the Urban District Council on Wednesday it was decided to serve notice upon the tramways company, who are building an electric lighting station, to sell to the Council the portion of land acquired by them for that purpose, and any additional land required for the erection of a plant for the lighting of Cleethorpes by electricity. It was stated that the cost would be over £30,000.

American Agency.—The McGuire Manufacturing Company, of Chicago, said to be the oldest electric truck manufacturers in the United States, are about to establish a factory in Great Britain. They have opened branch offices at 5, Warwick-court, High Holborn, where any information concerning their line can be obtained. Pending the establishment of a factory in this country, orders will be supplied from the Chicago works.

Paris Exhibition Awards.—The Campbell Gas-Engine Company, Limited, Halifax, have received a gold medal for their exhibit of gas and oil engines at the Paris Exhibition, and in addition to this no less than seven members of their staff, foremen and workmen, have been awarded silver and bronze medals for the work which they have done in connection with the exhibit.—Messrs. Stern Bros., of London and Glasgow, manufacturers of lamps, have been awarded a grand prix and silver medal.

Digitized by Google

Eaglescliffe.—Yarm-road and the village are to be lighted by electricity.

Change of Address.—The offices of the City and South London Railway Company have been removed from King William-street to 71, Finsbury-pavement.

Aspull.—A special meeting of the Urban District Council will be held next week to discuss the question of obtaining an electric lighting provisional order.

East Molesey.—The Council have decided to obtain experts' advice with regard to the offer made by Edmundson's Electric Corporation to light the district.

Lynton.—The new town hall recently presented by Sir George Newnes has been fitted and connected with the mains of the Lynton and Lynmouth Electric Lighting Company.

Whitby.—The tenders received by the Electric Lighting Committee have been forwarded to Messrs. Preece and Cardew with instructions to advise the Electric Lighting Committee thereon.

Portsmouth.—At the Town Council meeting on Tuesday it was resolved to establish a municipal telephone exchange. It was stated that the rate would be about £5 per annum for each subscriber.

Thornhill.—The District Council have decided not to take any steps at present with regard to the Northern Counties Electric Supply Company's proposed electric lighting order for the district.

Brighton.—The surveyor's plans, elevations, and sections for the proposed electricity station at Southwick have been approved, and the surveyor is about to prepare an estimate of the cost of the work.

Golborne.—The District Council are deliberating with regard to the South Lancashire Tramways and Electric Lighting Company's proposed order for powers to supply electric light along the route of the tramway.

Yeadon.—A well-attended meeting of owners and ratepayers on Monday night endorsed a resolution passed by the District Council to petition the Board of Trade for an extension of the electric lighting provisional order.

Nuneaton.—Application is to be made to the Local Government Board for sanction to borrow a further sum of £2 000 on account of the electric undertaking (making a total of £18,000, instead of £16,000, as stated in the previous application).

Felixstowe.—The Electric Light Works Committee have informed Colonel Jelf, C.R.E., that they are prepared to instal the electric light in the new barracks, and in part of the hospital buildings, as desired by the military authorities.

Branksome.—The Bournemouth and Poole Electricity Supply Company, Limited, have given notice of their intention to lay cables for the supply of power and light in stoneware conduits beneath the pavement on the south side of Ashley-road.

Batley.—The Town Council have agreed to revised plans and estimates for works of electrical energy supply proposed to be carried out by the Corporation, and have resolved that instead of £22,231, as previously decided upon, a sum of £25,602 be applied for.

Personal.—Mr. Edward Dodd, for over 20 years with the late Mr. Edward Pritchard, M.I.C.E., F.G.S., of the firm of Pritchard and Co., civil engineers, London and Birmingham, is now practising as civil and consulting engineer at 37A, Waterloo-street, Birmingham.

W. T. Henley's Telegraph Works Co.—The first batch of letters of allotment and regret for the recent issue of W. T. Henley's Telegraph Works Company, Limited, ordinary and preference shares have been posted. Both classes of shares were largely oversubscribed for.

Eccles.—The rate for electrical energy for motor purposes has been fixed at 3d. per unit. Sanction has been received to the borrowing of £11,950 on electric lighting account. The following new electric cable will be laid: Leeds-road, 422 yards of cable; Brunswick-street, 460 yards.

Goole.—The clerk of the Urban District Council has been instructed to watch the interests of the Council and take the necessary steps with regard to the application by the company for electric lighting powers in Goole urban district, and also as to obtaining a provisional order for the Council investing them with electric lighting powers.

Embankment Lighting.—The building of the generating station near Charing Cross is nearly completed, and the electric lighting of the Victoria Embankment will be commenced about the beginning of November. The whole scheme will probably not be completed before next summer. There will be 144 lamps, divided into nine electrical circuits.

Driffield.—The Urban District Council on Monday decided to inform the Northern Counties Electric Supply Company that they could not consent to their applying for a provisional order to supply Driffield with electric light. The Chairman of the Gas Committee said when the question of providing additional storage for gas was ready for consideration, the committee might deem it best to recommend that a provisional electric lighting order be applied for by the Council.

Thurlstone.—The Guardians intend to instal the electric light at the union. As they have no power to join in the erecting of a plant, they have asked the neighbouring urban district council's to take the matter up and lay down a plant, and they have appointed two representatives to watch their interests and obtain all the information they can. The two Councils have been asked to appoint three members each as a deputation, and to meet with a view to proceeding further with the matter.

Hampstead.—The report on the Hampstead Vestry's electrical undertaking, just issued, states that the capital outlay since the commencement of the undertaking five years ago has been £162 212. The total receipts for the year amount to £30,661, an increase of £6,283 on the previous year. The gross profit amounted to £16,325, of which the repayment of principal of loans and interest absorbed £6,619. The total net profit since the commencement of the undertaking has been £20,586.

Liability of Trade Unions.—Owing to the decision of Mr. Justice Farwell in the Taff Vale case, employers of all kind of labour may now sue trade unions as corporations for damage sustained through the action of their agents. The only surprising feature in the case is that a similar decision has not been arrived at long ago. Trade unions have the right to hold property as corporate bodies, and where the privileges exist the liabilities must lay also. This will assuredly act as a damper upon the zeal of their emissaries.

Pritchett Accumulators.—We are informed that the business relations between Messrs. Pritchetts and Gold and Messrs. Venner and Co., of 6, Old Queen-street, Westminster, by which the latter firm have been sole selling agents for Pritchett accumulators for the past 4½ years, have been dissolved by mutual consent. We have been asked to state that firms who have previously dealt with Messrs. Venner and Co. for Pritchett accumulators, should in future communicate direct with Messrs. Pritchetts and Gold at their works, Feltham, Middlesex.

Carnarvon.—The Joint Committee of the Town Council and the Gwyrfai District Council dealing with the question of the proposed light railway to Dinas Dinlle and the electric lighting of the district have adopted a report, from which it appears that in the event of the promoters failing from any cause to obtain a light railway order, or, having obtained the same, failing to carry out the works, they will transfer to the two Councils the benefit of the electric lighting provisional order on payment of not less than half the costs incurred in obtaining the same.

Llandaff.—The Landaff and Dinas Powis District Council have adopted a report from the Electric Lighting Committee on the notices received from the Penarth Electric Lighting Company for permission to apply for a provisional order to supply the district with electricity. The committee stated that they also had an interview with Mr. Downing (of Messrs. Downing and Handcock), representing the South Wales Electrical Power Company, and recommended that it was not advisable to give any power to companies to obtain provisional orders.

Workmen's Compensation Act.—At Blackburn recently a labourer was fetching water for breakfast when he fell and was injured severely. He claimed compensation under the Workmen's Compensation Act. For the defence it was said that as the man did not fall 30ft. he was out of court; also, that as he was fetching water for breakfast he was not at work at the time. The case was heard last week at the county court, and the judge decided that the man was at work within the Act, and that although the scaffold from which he fell was only actually 29ft. high, the building itself was over 30ft., and this overcame the technical point raised.

Iron and Steel Institute.—Since the original programme of the Paris meeting of this institute was issued some important additions have been made. The members, about 400 in number, and ladies accompanying them, have been invited by Mr. Eugene Schneider to a reception at the Le Creusot Pavilion in the Exhibition on Sept. 18, and by the Commissioner-General and Mrs. Jokyll to a reception at the British Royal Pavilion on the following afternoon, Sept. 19. The members have also been invited to visit on Sept. 20 the works of the Compagnie Française des Métaux at St. Denis. This company manufactures steel tubes, but its operations are devoted chiefly to the working of copper.

Sheffield.—The Electric Light Committee have recommended a number of increases in salary to take place as from Dec. 1, 1900. A three years' agreement is to be prepared by the town clerk in each case, to terminate on Dec. 31, 1903. The chairman of the Electric Light Committee (Alderman Styring), the deputy chairman (Councillor Harrison), and Councillor Maxfield, along with the chief engineer and manager (Mr. Fedden), are to visit the Paris Exhibition and to inspect the electric lighting machinery there; and they have also been authorised to visit Frankfort and such other places they may think desirable with a view of inspecting and making enquiries as to the installations at those places.

Dudley.—At the Town Council meeting on Tuesday it was said, in regard to the increase in the prices which would be charged for public lighting after the 29th inst., that for years the Corporation had been trying to purchase the gasworks, but on every occasion they had endeavoured to do so they had failed, owing to the price asked being so large. Before the conclusion of the present year the inhabitants of the town would be able to choose between gas and electric light. He hoped that the burgesses would rally round the Council by taking the electric light and making the scheme a gigantic success. The increase in the cost of public lighting by gas would be about £270 per annum.

Ayr.—The report of Mr. A. J. Fuller, burgh electrical engineer, submitted at the meeting of the Town Council on Monday, stated that 3½ miles of cable had been laid and 72 connections made during the year, the number of consumers being now 372. The annual output from the works had gone up from 297,420 units to 425,639 units, representing an increase of 43 per cent. A substantial reduction had been made in the cost of production, the rate being 1·80 per unit, as against 2·03. With a revenue of £5,244 the department was able to meet working expenses, pay

Digitized by Google

the interest on capital, amounting to £1,530, and still have a surplus of £235 towards paying off the annual sinking fund. But for the unexpected increase in prices they should have been able practically to meet the whole of this sinking fund account.

Birmingham Municipal Technical School.—The winter courses commenced on Tuesday. The physics department, which is under the immediate direction of the principal, comprises classes in physics, electricity, and mathematics. The classes in electricity comprise science courses and technical courses. The instruction given is rendered thorough by arranging both lecture and laboratory work in connection with each class. An important new class in this department is one for the study of design in electrical engineering. In the mechanical engineering department the classes are arranged with the view of providing a fundamental knowledge of the theory and practice of engineering. In addition to the ordinary courses of instruction, special courses are provided dealing with important engineering subjects to meet the wants of civil and mechanical engineers and draughtsmen.

Bury St. Edmunds.—The Town Council have resolved to purchase 20 additional meters. The resident engineer's report, adopted at the last meeting of the Town Council, stated that a supply of current was commenced on Aug. 28, and no stoppage had occurred between sunset and half past 11 at night. When the accumulators were working it was believed the supply would be as near perfect as possible. Many services had been completed, and the remainder would be finished in a few days. Fresh applications had been received for supply of current in St. John's-street. It was, therefore, recommended that the main be extended to that street at a cost of £65. A sketch and estimate of the cost of the proposed new accumulator-house, prepared by the borough surveyor, was submitted. Several further instruments were required at an estimated cost of £40. The police station is to be lighted by electricity.

London Gazette—An adjudication order has been made out *re* F. L. L. Lindsay, Gorphwysfa, Llandegfan, Anglesey. The first meeting in the estate of the above will be held on Sept. 18 at 3 15 p.m. at the Ship Hotel, Bangor, and the public examination on Oct. 4 at 12 15 p.m. at Magistrate's Room, Bangor.—Adjudication orders have been made out *re* R. Foster, Bradley House, Nelson, Lancs., and W. Baker, 27, Ormerod-road, Burnley, Lancs. (trading as R. Foster and Co., at Adlington street, Burnley, also trading as the Nelson Electrical Engineering Company, Stobb-street, Burnley).—The last day for receiving proofs in the estates of E. J. Paterson, 125, Queen's-road, Finsbury Park, London, and C. F. Cooper, Norbiton Lodge, Kingston-on-Thames, Surrey (carrying on business as Paterson and Cooper, at the European Works, Pownall-road, Dalston), is Sept. 22. Mr. E. C. Moore is trustee.

Worcester.—From Sept. 29 the charges for electric current will be as follows: To private consumers, 6½*d.* and 3*d.* per unit; for the waterworks motors, 1½*d.* per unit; for the public arc lamps, an additional £2. 2s. per year for an all-night lamp, and an additional £1. 1s. for a half-night lamp, and for the public incandescent lamps an additional 5s. per annum. The increase is due to the great advance in the price of fuel. The committee's estimates for 1900 include an extra sum of £1,000 for coal. The Council have agreed, in consideration of Lloyds Bank and the rector and churchwardens of St. Nicholas permitting the erection of an electricity transformer chamber on the space between the bank and St. Nicholas church, and permitting the Council and its officers to have access through the gates fronting the Cross, to indemnify the bank and the rector and churchwardens against damage to their property from fire or explosion at the transformer chamber, and to pay the bank the annual acknowledgment of 5s.

Tiverton.—The Town Council have adopted the minutes of the Lighting Committee stating that they had received the report of the electrical engineer appointed by the Council on the electric lighting of the town. He gave three alternative schemes for working installations—viz., by water, steam, or gas power, with estimates of the probable cost of working, from which it appeared that the water scheme was the only one which gave promise of yielding a profit from the commencement. The committee felt it was advisable before reporting fully to the Council to ascertain if the water power scheme could be carried out, and as it would be necessary to obtain the sanction of the Board of Trade to the construction of a weir across the river, the Mayor and borough surveyor had laid the matter before the Board of Trade, with whom a considerable correspondence had taken place, and they were still conferring. The committee felt nothing more could be done until the Board of Trade's decision was given, and they would then submit Mr. Adams's report with their own recommendations for the Council's approval.

Newport.—At Tuesday's meeting of the Newport Town Council the Chairman of the Electric Lighting Committee proposed that the supply of electrical energy for power should be under the sole direction of the present committee. He asked for a definition of work, protesting against the dual control exercised now, and suggested reducing charges to induce smaller consumers to make use of electric motive-power. The chairman and others thought the matter might be dealt with in November next, when the new committees were appointed, and favoured the formation of a new committee to cover the whole work of generation, distribution, and use, now undertaken partially by the lighting and traffic committees. It was acknowledged that some friction had taken place between the two committees. After a long desultory discussion, it was eventually decided to give an instruction to the Selection Committee for the appointment of a new committee, which would really supplant the present two committees. Mr. H. F. Parshall was appointed engineer for the tramway traction and electric scheme. His estimate for a power station capable of running 35 cars was £85,000.

Hammersmith.—At the Vestry meeting on Wednesday a letter was read from the London United Tramways, Limited, stating their intention to apply to Parliament for power to construct tramways along (1) Askew-road, Paddenswick-road, and Dalling-road, to connect with the existing tramway in King-street, with that in Glenthorne-road; (2) Scrubbs-road, Wood-lane, Shepherd's Bush-road, Brook-green-road, and Fulham Palace road; (3) from Uxbridge-road Station, along Richmond-road, Netherwood-road, to Shepherd's Bush-road; (4) from Uxbridge road Station, along Norland-road, Latimer-road, Bramley road, Lancaster-road, Portobello-road, etc., to Royal Oak; (5) connecting Nos. 1, 2, and 3 at Broadway, and proceeding along Bridge-road, across Hammersmith Bridge to Barnes and Richmond; (6) from Hammersmith Broadway, along Hammersmith-road to Kensington Church; and stating that there would be certain improvements, street widenings etc., involved in the construction of these tramways, and that Mr. Clifton Robinson would be pleased to attend and discuss the scheme with the committee at any time they may make it convenient for the purpose.

West Ham.—At last week's meeting of the Guardians a letter was read from the Local Government Board acknowledging the receipt of a letter informing them of the circumstances in connection with the acceptance by the Guardians, subject to the conditions specified in their letter of June 30, of the tender of Messrs. Frank Suter and Co., Limited, of 66, Berners-street, for carrying out certain works in connection with the proposed installation of an electric lighting system at the workhouse. It was stated that, having regard to the fact of the estimated cost of the proposed installation, based upon the provisionally accepted tender, being so largely in excess of the original estimate—viz., an increase of £1,875, or over 40 per cent.—the Board thought the Guardians would do well to consider whether it would not be advisable to abandon the proposal to provide electrical generating apparatus at the workhouse, where there was but insufficient space for it, and either continue for a while to use gas as an illuminant or else enter into an agreement with the West Ham Town Council for the supply of electricity from the street mains. As regarded the latter alternative, the Local Government Board were advised that wherever there was a public supply of electricity available it was preferable for a Board of Guardians to use that supply for the workhouse than themselves to provide a private system of generating apparatus, thereby incurring all the responsibility and cost of increased labour, repairs of machinery, consumption of coal, etc., besides the risk of requiring increased boiler power. It was requested that the matter might be reconsidered by the Guardians in the light of the foregoing remarks.

Battersea.—At the meeting of the Vestry on Wednesday the following report was submitted by the Finance Committee: "Your committee beg to report that, in accordance with the resolution of the Vestry of July 25, they made application to the Public Works Loan Board for a loan of the sum of £5,147 for electric arc lamps and posts. The Board state, however, that they cannot entertain the application, having regard to the limited amount placed at their disposal by Parliament, and to the amount of loans which they have already granted; they further state that they can hold out no hope that they will ever be in a position to entertain an application by the Vestry for a loan. Your committee, therefore, recommend that application be made to the London County Council for a loan of the sum in question, and for an amount of £20,000 further on account of the amount sanctioned by the Council, in respect of the general electric lighting scheme." The Electric Light Committee reported that they had considered as to the laying of electric mains on both sides of certain roads so as to prevent opening up the roads for the purpose of supplying electrical energy to lamps and consumers on the opposite side of the road to which the mains are laid, and recommended that mains, arc-light leads, etc., be laid in Battersea Park-road at an additional estimated cost of £960; in Lavender-hill, at an estimated additional cost of £285; and in Lombard-road, etc., at an estimated cost of £1,300. The committee further recommended that the charge for lighting purposes be 5½*d.* per unit, and for motor purposes 3*d.* per unit, with a rebate at the rate of 1 per cent. per 1,000 units up to a total consumption of 10,000 units per annum, and above that a rebate at the rate of 0·66*d.* per cent. per 1,000 units up to 20,000 units per annum.

LIGHT RAILWAYS.

At the monthly meeting of the Dukinfield Town Council the clerk reported that the enquiry by the Light Railway Commissioners into the Hyde and Dukinfield light railway was fixed to be held at the Town Hall, Hyde, on Sept. 27.

The Commissioners will hold their enquiry regarding the projected Kidderminster and Bewdley electric railway line on Oct. 17, and not on Sept. 17, as previously announced.

A letter from the Beeston Urban District Council, asking whether the Nottingham Corporation would be likely to favour the construction of a light railway between Beeston and Nottingham is before the Tramways Committee of Nottingham.

The Commissioners have informed the Pemberton District Council that they will hold, on the 26th inst., a public enquiry at

Digitized by Google

the Wigan Municipal Buildings into the application for an order to authorise the portion of the Wigan light railways described as Railway No. 1, the application so far as it related to the remaining portions described as Railways Nos. 2 and 3 having been withdrawn by the promoters.

At the quarterly meeting of the Worcestershire County Council last Monday the Chairman urged that strong action should be taken to enforce their views upon the Board of Trade in the cases of applications to construct light railways in the county, so that adequate precautions against danger to the public might be secured. Their recent experience had been that it was useless to appeal against the orders of the Light Railway Commissioners, and he suggested that the matter should be brought to the attention of the County Councils' Association, which appeared to be the only body having any weight with the Board of Trade. This was unanimously agreed to,

A public meeting was held last week at Kingsclere with the object of promoting a light railway, passing through Kingsclere, and which will connect on the west with Highclere (on the Didcot, Newbury, and Southampton line), and Basingstoke an the east, connecting it with the South-Western main line. Resolutions were passed acknowledging the need of the railway, and pledging the meeting to support the application to the Light Railway Commissioners.

The Board of Trade have, we learn, recently confirmed the undermentioned light railway orders: (1) South Staffordshire Light Railway Order, 1900, authorising the construction of light railways in the boroughs of Wolverhampton and Wednesbury and the urban districts of Willenhall, Darlaston, Coseley, and Bilston, in the county of Stafford; (2) Barnsley and District Light Railway Order, 1900, authorising the construction of light railways in the borough of Barnsley, and the urban districts of Worsborough and Monk Bretton, in the West Riding of the county of York; (3) Gateshead and District Light Railway Order, 1900, authorising the construction of light railways in the municipal and county borough of Gateshead, and the urban district of Whickham, in the county of Durham; (4) South Staffordshire Light Railway (Extensions) Order, 1900, authorising the construction of light railways in the urban districts of Bilston, Willenhall, and Coseley, in the county of Stafford; (5) Bromsgrove Light Railways Order, 1900, authorising the construction of light railways in the county of Worcester, between Bromsgrove Railway Station, Bromsgrove Town, and Lickey End; (6) Peterborough and District Light Railways Order, 1900, authorising the construction of light railways in the county of Northampton, in the city of Peterborough, and the parishes of Walton and Peterborough Without, in the rural district of Peterborough.

At a recent meeting of the Blackburn Town Council a report was received from the Electricity and Tramways Committee, stating that having considered the report of the electrical engineers on the question of giving running powers to the proposed Blackburn, Rishton, and Whalley, etc., Light Railway Company over certain of the tramway lines in Blackburn; as to the supply of electricity to the company for working part of the proposed tramways of the company; and as to supplying electricity to the district of Rishton for lighting and power purposes, they recommended: (1) That the company be granted running powers from Furthergate, along Burnley-road, to the borough boundary, on condition that the company grant similar running powers to the Corporation over the company's lines from the borough boundary to the Rishton boundary at Hyndburgh Brook, on terms to be mutually arranged. The current for working the tramways to the borough boundary to be supplied by the Corporation. (2) That the Corporation offer to supply current to the company for working the proposed tramway within the district of Rishton on the following terms: the price to a minimum of 1½d. per unit metered at the works of the Corporation, at a pressure of 500 to 550 volts, and the company to agree to take or pay for a minimum quantity per annum. The company to provide such gear as may be required for the supply of the current to their tramways, and to provide such feeder and return cables as may be required, the Corporation to lay such of these as are within the borough at the expense of the company. (3) That in the opinion of the committee it is not advisable for the Corporation to obtain power for supplying electricity for lighting and power purposes within the district of Rishton. It was further recommended that the town clerk arrange for the insertion of clauses in the proposed order giving the Corporation the option of purchasing so much of the light railway as will be situate within the district of Rishton at a price to be fixed by an arbitrator appointed by the Board of Trade, in the event of (1) the liquidation of the company, (2) the borough of Blackburn being so extended as to include Rishton, and providing that in the latter event the purchase by the Corporation shall not annul the exercise of running powers by the company over any of the proposed tramways for the period for which the order may be granted. The report was adopted.

The Light Railway Commissioners have intimated that a public enquiry will be held at Brackburn Town Hall on Sept 25 as to the expediency of granting the Blackburn, Whalley, and Burnley light railways an order to authorise the construction of the above-named light railways.

At a meeting of the Elland District Council it was agreed that the seal of the Council be affixed to a communication approving the Deanhead light railway scheme, which the Council considered a necessity for the district.

The Port Madoc Urban District Council at a recent meeting expressed themselves in favour of the scheme proposed by the Manchester syndicate for an electrical light railway from Port Madoc to Beddgelert.

PROVISIONAL PATENTS, 1900.

SEPTEMBER 3.

15665. Improvements in and relating to automatic frogs for the overhead equipment of electric tramways. Edmund Philip Grove, 42, Hayes-road, Bromley, Kent.

15637. Improved electro-mechanical device for motorcars and the like. William Phillips Thompson, 322, High Holborn, London. (Eugenio Cantono, Italy.)

15612. Improvements relating to electric incandescent lamps. Louis Jean Paul Hollub and Henry Mignal, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SEPTEMBER 4.

15761. Improvements in electrolitical apparatus. Joseph Matthews and William Davies, 77, Colmore-row, Birmingham.

15716 Improvements relating to electric storage batteries. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (William Rushton Bowker, United States.) (Complete specification.)

15713. Improvements in or relating to overhead trolley wires or conductors for electric traction, overhead electric cables, or the like. Robert Hacking, 111, Hatton-garden, London

15717. Improvements relating to electric railways working on the closed conduit system. Léon Dion, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

15718. Improvements relating to the preparation of conducting material chiefly designed for the manufacture of brushes for dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Jesse B. Fay, United States.)

15721. Improvements relating to telephone systems. Henrik Tore Cedergren and Gottlieb Magnus Teodor Piltz, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

15725. Improved means and appliances connected with electric arc lamps. Charles Bean King, jun., Eric Rivers Smith, and John James Rathbone, 166, Fleet-street, London.

15730. An improved material or composition suitable for use as an electrical cement and insulator. Edwin Tatham, 47, Lincoln's-inn-fields, London.

15746. Improvements in arc lamps. Guy Carey Fricker, 46, Lincoln's-inn-fields, London.

15748. Improvements in or relating to electric switches, fuses, and other apparatus in which destructive electric arcs are liable to be formed. Gerald William Partridge, 46, Lincoln's-inn fields, London.

15752. Improvements in and relating to electroliers, pendants and fittings or connections therefor. Hugo Hirst and George Henry Ide, 165, Queen Victoria-street, London.

SEPTEMBER 5.

15774. An improved electrical signalling apparatus for fire alarms and other purposes. Walter Clar, 1, Broad-street-buildings, Liverpool-street, London. (Complete specification.)

15793. Improved electric travelling contact appliances for establishing telephonic and signal communication on railways between the signalman in the box and the driver of a locomotive. Harry Gulliver and Thomas Crow Fowler, Clun House, Surrey-street, Strand, London.

15818. Improvements in and relating to electrical signalling apparatus. Henry Montague Hozier, C.B., and Alexander William Sharman, 45, Southampton-buildings, Chancery-lane, London.

SEPTEMBER 6.

15864. Improvements in and relating to street lamp fittings for incandescence electric lamps. William Charles Cloete Hawtayne, 73, St. Stephen's-road, Upton Park, London.

15865. Improvements in shades for electrical and other lamps. William Edward Langdon, 73, St. Stephen's-road, Upton Park, London.

15870. Improvements in apparatus for producing electric waves. Tebaldo José Ricaldoni, 46, Lincoln's-inn-fields, London. (Complete specification.)

15872. Improvements in arc lamps. John Lenderyou and Tom Samuel Millward Wyatt, 22, Southampton buildings, Chancery-lane, London.

15874. Improvements in means or apparatus for controlling electrically-driven lifts, hoists, cranes, pumps, or air compressors and for analogous purposes. Jörgen Björnstad, 47, Lincoln's-inn-fields, London.

15888. Improvements in electric meters. John Corry Fell, 1, Queen Victoria-street, London. (William Stanley, United States.) (Complete specification.)

SEPTEMBER 7.

15890. Improvements in electric cable connectors. Stanley Beeton and Mark Barr, Green Bank, Bowden, Cheshire.

15907. Improvements in electric arc lamps. Frederick Booker, 22, Ashchurch-terrace, Shepherd's Bush, London.

15918. Improvements in electrical phase transformation. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Alexander D. Lunt, United States.) (Complete specification.)

15919. Improvements in electric rotary transforming apparatus. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Albert G. Davis, United States). (Complete specification.)

15920. Improvements in electric furnaces. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

15921. Improvements in electric cut-outs. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William Le R. Emmet, United States.) (Complete specification.)

15951. An automatic switch for groups of transformers with members of various capacity. Alfred Schlatter, 18, Buckingham-street, Strand, London. (Complete specification.)

15965. Improvements in or relating to electric barometers or barometric indicators. Alfred Julius Boult, 111, Hatton-garden, London. (Comte Alberto Miglioretti, Italy.)

SEPTEMBER 8.

16000. Improvements in electric switches. Veritys, Limited, and William Reginald Ridings, 322, High Holborn, London.

16013. Improvements in secondary batteries. Charles Orme Bastian, 77, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Sept. 29.

1899.

17722. Telegraphic apparatus. Crehore and Squier.

18065. Secondary galvanic batteries or accumulators. Lucas and New.

18754. Galvanic batteries. Meyer.

19781. Electrical switches. Hunter.

21876. Magnetic separators. Clark. (Courtney.)

21900. Cord grips for electrical apparatus. Oppenheimer. Actien-Gesellschaft Mix and Genest.)

21901. Porcelain interiors for electric incandescent lamp-holders. Oppenheimer. (Actien Gesellschaft Mix and Genest.)

22271. Manufacture of electrical heating appliances of high electrical resistance capable of sustaining high temperatures. Vogt.

22330. Process of manufacturing carbons for electrical and electro-chemical and other purposes. Pohl.

1900.

2240. Telephones. Ducretet.

7631. Electric clocks. Lake. (Dudley.)

8226. Plates for secondary batteries. Schmitt.

9767. Coupling or connecting electric conductors, cables, and the like. McTighe.

10128. Voltmeters. Duncan.

10124. Alternating-current wattmeters. Duncan.

12870. Trolley for overhead electric traction. Johnson, Palmer, and Coenen.

13200. Arc lamps. Ackermann.

NOTES.

Personal.—We learn that Mr. L. R. Wilberforce, M.A., demonstrator in physics at the Cavendish Laboratory, Cambridge, and university lecturer in physics, has been appointed to the Lyon Jones chair of experimental physics at University College, Liverpool, vacated by the removal of Dr. Oliver Lodge to the University of Birmingham.

Indian Telegraphs.—We have before mentioned what a large amount of valuable work is done by the Government Telegraph Department in India, and we now learn that, in addition to sending messages and building lines for its own use, it supplies the State railway and canal systems with wires, instruments, and the technical direction of their telegraph offices. Thus at the end of the last official year, no less than 56,344 miles of wire and cable were maintained for railways and canals, and 2,374 railway and canal offices had the benefit of the Telegraph Department's technical supervision.

Umpiring by Electricity.—We notice in the *Daily Telegraph* an account of a review by General Brugere of the troops engaged in the military manœuvres at Chartres. In this account our contemporary states that General Brugere, one of the military umpires, went along the lines in a motorcar, behind him being an electric "volturette" with a strong light projector. The latter was brought to bear on the position to be attacked, and it said to have been worked with remarkable efficiency. The searchlight showed every part of the ground and every regiment, both in the attacking and the defending contingents.

South American Tramways. — Electricity is apparently becoming very popular in the South American countries as a motive power for tramways. Thus the Chilian Electric Tramway and Light Company, which has some 42 miles of horse tramways, is soon to convert them into electrical. La Capital Tramways Company, of Buenos Ayres, Argentina, has also acquired the systems of the New and Grand National Tramways Companies, and intends to convert both these systems to electrical traction. La Capital Tramways Company has already spent some very large sums in equipping portions of its line electrically.

Finsbury Technical College.—The evening courses of the Technical College, Finsbury, begin on Monday, Oct. 1. Prof. Silvanus Thompson will open the Monday evening (advanced) course with an introductory lecture on "The Distribution of Electricity," the succeeding Monday evenings until Christmas being devoted principally to the subject of the design of continuous-current dynamos and motors. On Wednesday evenings Dr. E. W. Marchant will lecture on electric currents and methods of measurement. Prof. Thompson will also give a short course of special lectures on Fridays on the "Polarisation of Light."

Aluminium Welding.—It is stated by the *Trade Journals Review* that the great difficulty of welding, which has been the drawback in the use of aluminium, has been overcome. Thus the well-known firm of W. C. Heraeus, of Hanau, near Frankfort-on-the-Main, has now succeeded in welding aluminium without the use of any other metal, solder, or acid. The process is kept secret at present, but it is stated that no seam can be detected, and that the welded pieces can resist blows and temperature variations as well as if they had always formed a whole. If this fact is correct, it will considerably heighten the value of aluminium.

The Birkbeck Institution.—This institution, we learn, commences its new session on Oct. 1. There are both day and evening courses of study, comprising various branches of commercial and technical education. During the recess considerable additions and improvements have been made by the aid of a gift of 2,000 guineas from Mr. F. Ravenscroft, to commemorate his completion of a membership of 50 years. A new reading-room, a new magazine-room, and a social room have been provided, and a well-appointed metallurgical laboratory has been added. A popular lecture or entertainment is given in the theatre every Wednesday evening.

Mining Engineers.—Coal is of great interest just at the present time owing to its high price and in view of the approaching winter. The eleventh annual meeting, therefore, of the Institution of Mining Engineers, which has just been held at Bristol, is of general interest. The secretary's report, read at the opening meeting on Tuesday, showed that the membership numbered 2,393. Papers were read by Messrs. J. and G. E. MacMurtie on "The Geological Formation and Working of the Bristol and Somerset Coalfield," this coalfield including an area of 238 square miles. Other papers were read by Messrs. W. A. E. Assher and E. Gledhill.

Electricity in Brussels.—In a report prepared by Alderman de Potter on the electric lighting of Brussels, it is shown that the city possesses three electricity stations operated either by steam or gas. The most important contains five steam-engines of 500 i.h.p., driving 18 dynamos of 1,100 amperes at 150 volts, besides a battery of accumulators furnishing a discharge of 700 amperes for eight hours. The distribution is carried out by means of underground ducts, the total length of which on Dec. 31 last was over 31 miles. In a certain number of streets the conduits exist under both the footways. The number of lamps installed on Dec. 31, including public lighting, was 84,954.

China Cables.—It is pleasing to hear that the Eastern Extension and Great Northern Telegraph companies have successfully laid and opened for traffic a submarine cable between the towns of Shanghai and Chefoo. This is an important piece of work, as with the cable recently laid between Chefoo and Taku it provides a means of cable communication to Chefoo and Taku which is entirely independent of the Chinese land lines, and without any additional tariffs. These cables may yet prove of valuable assistance to the Allied troops in China, as will probably the lines which the companies also announce as having laid between Chefoo and the British port of Wei-hai-wei, and also between Chefoo and the Russian town of Port Arthur.

The Civil and Mechanical Engineers' Society. We have received the list of meetings and officers of the Civil and Mechanical Engineers' Society for the session 1900-1. The president is this year Prof. Robert H. Smith, the vice-presidents being Messrs. W. M. Bering and W. N. Twelvetrees. The papers to be read during the session, which commences on Oct. 4, are the president's address on "Training to Keep Ahead in the World Competition"; "Patent Law," by Mr. G. F. Emery; "Valve Gears and Valve Diagrams," by Prof. R. H. Smith; "The Case for Electric Power Distribution," by Mr. W. B. Esson; "A Description of the Staines Reservoir Works," by Mr. M. Mawson; "On Authoritative Rules for Unit Stresses in Railway Girders," by Mr. Jas. R. Bell; "On the Proportions of Cylinders for Multiple-Expansion Engines," by Mr. A. Haussen; and "The Storage of Electricity," by Mr. A. H. Allen.

Street Railway Convention.—We gather from the American technical Press that the annual convention of the American Street Railway Association is to be held at the Convention Hall, Kansas, on Oct. 16, 17, 18, and 19.

Digitized by Google

The congress, which promises to be a very interesting one, will be the nineteenth, and a number of very interesting papers are down on the agenda. Amongst these are papers entitled "Double-Truck Cars: How to Equip them and obtain Maximum Efficiency under Varying Conditions," "Comparisons of the Various Systems of Electrical Distribution for Street Railways," "Consolidation of Street Railways and its Effect on the Public," "The Storeroom and Storeroom Accounts," and "Painting, Repainting, and Maintenance of Car Bodies." Friday, Oct. 19, is to be set apart for viewing the exhibits, the annual banquet being held on this evening also. At this banquet the officers-elect are duly installed.

Swiss Electricians.—We notice that it is announced that the combined general meeting of the Association Suisse des Electriciens and the Association des Centrales Suisses d'Electricité is to be held this year at Basle on Oct. 6, 7, and 8. It is proposed on Oct. 6 to hold the general meeting of the Association Centrales Suisses, and on Sunday, Oct. 7, that of the Association Suisse des Electriciens. After this last meeting a banquet and *réunion* is to take place. On Monday, Oct. 8, visits are to be paid to various installations in the neighbourhood. The annual report for 1900 of the secretary of the Association Suisse des Electriciens has just been published. It contains the usual information, but also, in addition, hints as to the establishment and safe working of installations for use with high-tension currents, and a report on the electrical installations at the Paris Exhibition from the point of view of safety. There is also a list of Swiss patents issued in 1899, etc.

A New Electrolytic Cell.—The following abstract, which appears in the *Journal* of the Chemical Society, was contributed by Mr. W. L. Hildburgh to the *Journal* of the American Chemical Society. The abstract reads as follows: "The cell Cu | H_2SO_4 | Pt allows currents of low voltage to pass if the copper is employed as the anode, but if the current is reversed owing to the high polarisation no current passes if the voltage is not too great, and hence such a cell may be used as a rectifier for low-voltage alternating currents. This is not a very efficient arrangement, however, and a better form consists of a plate of platinised platinum, partly in sulphuric acid, partly in hydrogen, and a platinum wire sealed into glass under the acid. The whole is contained in a sealed vessel. Currents may pass from the platinum plate to the platinum wire, generating hydrogen at the wire, which escapes in bubbles, joining the gas above the acid; in the opposite direction, however polarisation occurs, the wire becoming coated with a film of oxygen. For high E.M.F.'s a number of these cells in series may be employed."

Electrochemical Equivalent of Carbon.—The following abstract, which appears in the *Journal* of the Chemical Society, is of a paper contributed by Mr. S. Skinner to the *Proceedings* of the Cambridge Philological Society. The abstract is as follows: "When a solution of potassium permanganate is electrolysed with a carbon anode, 77·86 per cent. of the gas liberated at the anode consists of carbon dioxide, the rest being carbon monoxide and oxygen. The total volume of gas liberated is nearly the same as the volume of oxygen liberated by the same current in a dilute sulphuric acid voltameter. The permanganate ion persists in solution even although a quantity of electricity more than sufficient for its complete decomposition is passed through the cell. The author finds the electrochemical equivalent of carbon to be three times that of hydrogen. A cell may be constructed with a carbon rod in potassium permanganate, and a lead peroxide plate in dilute sulphuric acid, the two electrolytes being separated by a porous pot. The E.M.F. is 0·33 volt, and acts externally from the lead peroxide to the carbon. In this self-acting system carbon is consumed at the ordinary temperature.

Central London v. Metropolitan.—We gave last week a few figures showing the effect of the competition by the Central London Railway on the omnibus receipts. The *Financial Times* now points out that this decrease in receipts has not appeared in the case of the Metropolitan Railway. Figures are given showing the increase or decrease of the receipts of this company for several days of August and September as compared with the same days last year. Thus the receipts for Aug. 8 show an increase of £169, those for Aug. 15 an increase of £66, those for Aug. 22 a decrease of £170, and on Aug. 29, Sept. 5, and Sept. 12 considerable increases were shown. This result, although it was not to be expected that the new line would seriously affect the old, does not quite show the matter properly. For instance, on the District Railway the line from Hammersmith and the stations near by does appear to be affected, as the trains which used to be considerably overcrowded in the morning and evening are now half empty. This must have some effect on the District Company's receipts, and the Metropolitan Railway are to be congratulated if they do not find the same state of affairs on a portion of their line.

An Electrical Hospital.—A peculiar experiment is about to be tried in St. Louis, this being a hospital which is to be fitted up entirely with electricity. The head of the concern is said to be Dr. Heber Robarts, and he states that the hospital will be as nearly a battery as it can be made. It is to be fitted with every kind and variety of electrical apparatus that has anything to do with the generation of electric currents. The expenditure of a large sum of money will be necessary to provide the appliances which will be required, as all of these, says *Electricity* of New York, will be of the most delicate order. The funds needed, however, are apparently forthcoming. The hospital will be a thoroughly legitimate institution, and will not be operated on a cure-all basis. The patients are simply to be treated by electricity and the best results obtained. The staff of the hospital will be regular medical practitioners who have given special attention to troubles which it is almost impossible to treat properly in the old way. The staff have no intention of abandoning medicine in favour of electricity, but state that they are not going to administer it in the same way. They propose to diffuse it through the affected parts by means of electric currents and electrodes.

Electrolytic Deposition.—The following is an abstract of a paper contributed by Mr. Louis Kahlenberg to the *Journal fuer Physikalische Chemie*. The abstract appears in the *Journal* of the Chemical Society, and reads as follows: "In order to test whether Faraday's law is valid for non-aqueous solvents, solutions of silver nitrate in pyridine, aniline, phenyl cyanide, and quinoline were electrolysed, and the weight of silver deposited compared with that deposited from an aqueous solution in the same circuit. The weights respectively were as follows, those from the aqueous solutions being given first: 0·7836 grm., 0·7819 grm.; 0·1788 grm., 0·1780 grm.; 0·1612 grm., 0·1603 grm.; 0·2501 grm., 0·2452 grm. In the quinoline solution there was evidence of a complicated reaction, as the silver was carbonaceous; in the other solvents it was firm and white. Experiments with lead and antimony gave very similar results. The work must be considered as preliminary, but it certainly tends to show that Faraday's law is valid for the non-aqueous solutions. It was found also that silver can be completely deposited in a compact white

Digitized by Google

form from solutions in pyridine, or in aqueous pyridine, by a current of density of from 0·17 to 0·25 ampere per 100 square centimetres cathode area."

Electric Lighting at Budapest.—Some information given by M. de Fodor at the Paris congress on the electric lighting of Budapest will be of interest to all electrical engineers, as giving a new means of improving the load factor of an electric lighting station by means of a variation in price. The nearest approach to Mr. Fodor's system in England is that arranged by Mr. A. Wright at Whitechapel. In fact, we believe that the Whitechapel charges are even more favourable to the consumer than those at Budapest. Mr. Fodor states that it was found that the average number of hours which each lamp connected to the network was used, amounted to 440 per annum. These were divided up amongst the various months in the following way: January, 60 hours; February, 50 hours; March, 36 hours; April, 29 hours; May, 19 hours; June, 12 hours; July, 9½ hours; August, 14 hours; September, 29 hours; October, 50½ hours; November, 64 hours, and December, 67 hours. Under these conditions the author points out that the consumers ought to be encouraged in the months in which the works are least used, and he does this by making a reduction in the case of those lamps which use more than the normal. In the summer months this reduction amounts to 60 per cent. of the standard charge; in the spring and autumn months, to 40 per cent.; and in the winter months, to 20 per cent. By this system no special apparatus is required, and it is stated that it works to the satisfaction of the consumer. It seems to us, however, that the system is a somewhat complicated one.

German Tramway Accidents.—There has, we learn, just been completed by the Society of German Tramway and Secondary Railway Administrations an exhaustive enquiry as to the causes of accidents on electric tramways. The above-mentioned institution comprises about 100 different tramway and light railway undertakings, and its report contains particulars relating to some 58 tramways. The report, which deals with the year 1899, was presented at the society's annual meeting, which, we learn from the *Financial Times*, was held last week in Wiesbaden. From this report we notice that during 1899 accidents occurred to 973 passengers and 871 other persons, or 52·8 per cent. and 47·2 per cent. respectively. Of the total of 1,844 no less than 126 were killed, whilst 147 passengers and 146 other persons were severely injured. The report concludes that, as compared with 1898, there was a diminution last year in the number of accidents arising from persons unlawfully entering or leaving tramcars and from too high a speed being used in passing round curves, and a reduction in the casualties to children was also noticed. The result in the latter case is attributed to the adoption of improved mechanical braking arrangements. There was, however, an increase in the accidents due to collisions, the larger number affecting pedestrians, and especially cyclists. The percentage of accidents on these railways seems to be abnormally high, and one is inclined to think that more care might be exercised by those controlling the lines. We are not told what proportion of accidents occurred owing to electrical matters, but as it is not mentioned we presume it must be very small.

Technical Education.—With the approach of the winter session come the prospectuses of the various technical institutions. Thus we have received the prospectus of the Northern Polytechnic Institute, Holloway-road, N. This prospectus contains a considerable amount of reading matter relating to the various classes which are about to be held in the institute, and also has some good illustrations of the shops, halls, etc., of the building. The classes in electrical engineering are to include three courses, the first for very elementary students, the second for more advanced students, and the third for those who have passed the second course. With each of these courses laboratory work is taken. Mr. Mundella, the lecturer in this section, also has a class for electric wiring and fitting. There are a large number of other classes also in preparation, including both technical and commercial subjects. The principal of the Northern Polytechnic is Mr. J. T. Dunn. We have also received the calendar for the fifth session of the Royal Technical Institute, Salford, of which the principal is Mr. W. Wilson, M.A. In this institute is a very large number of classes which are practically all technical. In the physical and electrical engineering department, in which we are more particularly interested, the lecturers are Messrs. W. B. Burnie, E. S. A. Robson, E. H. Dixon, and M. H. Barnes, and there are classes for elementary and advanced students in electrical engineering, lighting, direct and alternating currents, wiring and fitting, electric traction and motors, central stations and distribution, etc. There are many other subjects taken, and the chief industries of Manchester and Salford are taught in the dyeing, printing, and bleaching department, which deals with the treatment of cotton goods.

Obituary.—We regret to have to record the death of Mr. Abdank-Abakanowicz, who for many years occupied a prominent position amongst the electrical engineers in France. He was born in 1852 in Lithuania, and commenced his technical studies at the polytechnical school at Riga. The deceased went to Paris in 1881, since which time he took an active interest both in the electrical industry and in the technical papers in that city. He was one of the original founders of *L'Industrie Electrique*, and it is from the obituary notice in that paper that we take the following facts. Like other early workers in the field of electricity, Mr. Abdank invented an arc lamp and also a dynamo, but his magnetic call system, which is so largely used on railways, obtained the greatest success of his earliest inventions. In connection with the 1889 exhibition in Paris he was dispatched as commissioner to the United States to induce the large electrical firms of that country to exhibit. The result was that the American section was one of the successes of the exhibition, and the Cross of the Legion of Honour was awarded Mr. Abdank for his labours. It was through this visit that he became connected with Prof. Elihu Thomson, and also with the Thomson-Houston International Company. Accordingly, when the company blossomed forth as the powerful Compagnie Française Thomson-Houston, he was appointed their consulting engineer. In this connection he did a great deal of work in the development of electric traction in France. He was also largely responsible for the establishment of the laboratory at Parc St. Maur. In this some valuable original work has been carried out. We gather from the columns of our contemporary that his colleagues on the staff of the above-mentioned company feel the loss not only of his expert advice, but also of a sincere friend.

A Cyclist's Lawsuit.—We notice in the *Street Railway Journal* for September an account of an interesting law case at Alleghany between a cyclist and a tramway company. The facts were that the plaintiff, an inexperienced cyclist, rode on to the railroad track when a car proceeding on a down grade was right behind him. He started to ride up the track in order to turn off, but had only proceeded some 140ft. when he was struck by the car and thrown down. The judge dismissed the suit for damages against the company on the ground that the plaintiff was guilty of negligence. The judge also stated that he had long been

Digitized by Google

impressed with the belief that the courts should take a firm hold of these cases where men risk their lives by just going before a car or travelling on a track before a car. If the plaintiff could be sustained in his action the result would be that bicyclists would get on to the track of a street railway, plod along that track, and expect that the motorman of the car would stop to let them off rather than hit them; and if this were the law, perhaps one-half the street cars would be delayed in their trips. We are afraid that the judge in question has not considered the other side of his verdict very much. It would seem that if any cyclist happened by chance to cross a street railway track, the motorman of a car coming along has full power to go full speed for that cyclist, and knock him over and perhaps kill him. He would, we should think, receive the judge's commendation for so doing. It seems to us, however, that in this instance we do things better than our American neighbours, in that we have a law making the obstruction of tramway cars a punishable offence. This is certainly not taken much advantage of, but it does not take many examples in the shape of smart fines to make cart drivers and cyclists get off tramway tracks when they hear the gong or whistle of the tramcar. In any case it would seem very peculiar law which allows a man to be seriously injured, or perhaps killed, when a fine of a pound or two would meet the case.

Submerged Accumulators.—A remarkable case of accumulators working while under water is spoken of in the *Scientific American*. The accumulators formed part of the municipal electric plant of Munich, the station of which is situated on an island formed by the Isar, and during the inundations of last year was partially submerged. The batteries of accumulators, which were on the ground floor, were first reached, and were soon entirely covered. One of the batteries was used on the city lighting circuit, and the other was connected in parallel with the dynamos for the traction system. As the tramway service had to be discontinued, the second battery was removed from the circuit, and it was thought that the batteries for the lighting circuit would also have to be cut out, as the flywheels of the engines were half under water, except two. Nevertheless, as it was almost indispensable to light at least the principal streets of the city, it was decided to try to operate the submerged battery. The attempt was successful, and the battery, which had been constructed to give 6,000 ampere-hours with a 600-ampere discharge, was able to furnish 4,000 ampere-hours during the night; the remainder was lost in discharges in the water. Encouraged by this success, the engineers charged the battery on the following day, and the discharge was repeated under the same circumstances. Two days after the water had lowered sufficiently to give access to the battery-rooms. It was found that the density of the acid had fallen, but not to a very great extent; from 22deg. B. it had fallen to 20deg. B. only, there having been scarcely any diffusion. Except for a layer of mud ¼in. thick upon the top of the plates and the connecting rods, the inundation had left scarcely an appreciable trace. It was supposed at the beginning that it would be necessary to replace the acid of the batteries, which represented a considerable expense, as they contained more than 30,000 gallons, but as the acid held its strength, a slight strengthening was all that it required.

Accumulator Traction.—We noted a month or two ago the removal of the last accumulator cars in Chicago, and now we hear of the same thing at Berlin. Thus we gather from the *Financial Times* that, in consequence of many interruptions in the service and of accidents on those sections of the Berlin tramways worked by means of accumulator cars, the German Ministry of Public Works recently appointed a technical commission to investigate the question of the suitability of these storage battery cars for the heavy traffic prevailing in that city. The unanimous report of the commission, which has just been issued, states that accumulator traction still exhibits great imperfections, and that it requires serious deliberation both in regard to security of working and safety of the public. As far as the exercise of tractive force is concerned, the method is far behind the overhead trolley or the underground conduit system; the charging of the batteries has to be too frequently performed, and, if charged from overhead trolley wires, the method also has considerable technical difficulties. The report submits that the batteries are so heavy as to undesirably increase the weight of the tramcars, with the result that, apart from the excessive wear of the rolling-stock, the car bodies are frequently damaged, and lead to interruptions in the traffic. The accumulators are dangerous from a fire standpoint, and in winter time, when the cars are closed, the development of acid fumes is not only oppressive to passengers, but also dangerous to health. On these grounds the commission concludes that storage battery cars are not suitable for the heavy street traffic of Berlin. As a result, it has been decided by Imperial authority to gradually abandon the use of accumulator cars on the Berlin tramways, and to substitute the overhead trolley system, except in special busy sections, where the underground conduit method will be introduced. We are sure that the citizens of Berlin will benefit by the change, and we think that the Public Works Department will also find that by adopting the overhead trolley system the cost of working will decrease.

A Scale of Charges.—The Electric Lighting Committee of the parish of Fulham has recommended the Vestry to accept as their scale of charges one drawn up by their consulting engineer, Mr. Medhurst. The general principle underlying the scale is that the consumer having the best average load should receive electricity at the cheapest rate. The fault connected with it is that the reduction is made on the basis of electricity consumed per 8-c.p. lamp installed. This with anyone looking into the system as a business man, will discourage the use of electric lighting in any place where the lamps are not likely to be used regularly, as such lamps would increase the bill. It is proposed that in Fulham consumers should pay 5d. per unit until the average quantity of 12 units per 8-c.p. lamp fixed has been consumed in any year. Beyond this figure and up to an average of 18 units per lamp, 3d. per unit will be charged, and above the average of 18 units per lamp, 1d. per unit. It is also suggested that the discounts should be deducted during the last quarter of the year, so that there may be, with a good consumer, a great difference in the bills for the March quarter and the December quarter, in spite of the fact that approximately equal quantities of electrical energy are consumed. This course of giving all the reduction towards the end of the year will greatly facilitate the book-keeping and accounts, as during the earlier quarter a flat rate of 5d. per unit will obtain. We think, however, that the extra labour each quarter of working out a compound rate is quite warranted in view of the encouragement which the reductions in the March quarter would give to consumers. The scale will give a cheap supply to the inhabitants of the parish of Fulham, and its only defects are those mentioned above, of which the most important is that of discouraging the use of electric light in the private rooms over shops and in other places where a regular supply is not required. We note, by-the-bye, that the charge for each of the 80

Digitized by Google

are lamps included in the first scheme is to be £20 per annum, and these will replace 163 gas lamps.

The Ostrich.—One of the facts in natural history usually accepted is that an ostrich, when it wishes to hide itself for any reason, puts its head into the sand, and believes that because it can see nothing its large body is effectually hidden. If equal acceptance could only be given to the theory of the transmigration of souls, one would believe that a certain amount of this characteristic of the ostrich existed in the mind of the editor of the *Journal of Gas Lighting*. The characteristic in question is particularly shown in the last issue of the above-mentioned journal, in which the gas affairs at Sheffield are referred to. We gather from the report "that the gas company in that town is exceedingly well managed, and that it has developed incandescent gas lighting to its utmost limits, in that the company now maintain no less than 30,000 two-light meters, which shows that they must supply a very large number of small consumers." The editor of our contemporary adds that the success of the gas company is evidently an explanation of the fact that the Sheffield Corporation are going to light their sewage works with electricity because "there will be small demand for it in the town." Seeing that the consumption of electricity is increasing at the rate of 30 per cent. per annum in Sheffield, a remark of the above kind is distinctly out of place. The particular point, however, in this week's issue of our contemporary to which we would call attention is one respecting "The Future of Light and Power Distribution," which is said to be a "communicated article." We are not quite clear whether the editor believes that his readers are also like the ostrich, but we should have had more faith in the article in question if it had been placed on the advertisement sheets. We have a great admiration for the Westinghouse gas-engine, and also for the way in which the Westinghouse Company manage their commercial business, but we do not care to see their circulars inserted in technical journals under the heading "Communicated Article." The statements in the advertisement in question are, of course, most interesting, but they are not supported by any facts, and particularly we notice that all reference to cost of upkeep of the engines advertised is omitted.

Alloys. — Amongst the papers read at the recent meeting of the British Association at Bradford was one by Mr. F. H. Neville on the "Nature of Alloys." The paper contained an abstract of the report of the British Association Committee on the subject. Thus it was stated that most students believed that certain definite chemical compounds existed in alloys. To prove this, however, certain means must be adopted to abstract the particular compounds. Ordinary chemical means of isolation were of no use under the circumstances. Fractional solution was effective in some cases, and by means of it several distinct metal compounds had been isolated from alloys, such as platinum-tin, copper-tin, zinc-copper, and other compounds. Another method was by observation of the "freezing point"; the molten mixture was cooled down slowly, and the temperature noted at which solid matter began to separate from the liquid. This varied with the proportion of the constituents, and by making many observations with varying proportions, a curve could be obtained of these solidifying temperatures, any irregularity pointing to the formation of something other than a mere mixture. By this means many interesting facts had been indicated which had subsequently been rendered evident by examination under the microscope. Valuable and interesting results had been thus obtained, both in this country and abroad. A remarkable instance of peculiarity was exhibited by mixtures of aluminium and antimony when all the mixtures froze at a higher point than either of the components, and showed two irregularities indicative of two distinct compounds. In these mixtures it appeared that the component that predominated to a considerable extent acted as a solvent to the compound formed with the other component; but as the proportion of the other component was increased the conditions became reversed. Interesting results had been obtained by observing not only the freezing point, but also the point where the whole mass solidified, so that for every mixture the exact composition of the mass from which the compound had separated and of the separated compound was indicated. Röngten-ray photography had also been utilised to demonstrate the formation of these intermetallic compounds. A long list of known and supposed alloy compounds was given in the report, and it appeared that the atomic relations generally held by chemists did not hold in the case of alloys.

Extensions.—The question of extensions in electric lighting stations is one of the utmost importance, as it is impossible to obtain additional machinery at a few months' notice. It, therefore, behoves all engineers responsible for the supply of electric light in towns to look well ahead, and to consider not only what the demand will be each winter, but also the fact that electrical contractors are human, and that a great number of them err by promising and then not keeping up to their specified dates. We believe that if a critical examination were made of all the electric light stations in Great Britain, it would be found that the plant in them was not sufficient at the present time to provide for the winter's load after allowance is made for a reasonable amount of spare. In other words, a chance breakdown, such as cannot be foreseen and prevented even by the best of electrical engineers, may seriously hamper the continuity of supply in certain of our large towns. That this was so during last winter was proved by the lamentable number of cases in which accidents occurred, resulting in a temporary interruption in the lighting owing to the want of reserve plant. It is, of course, rather difficult to persuade the untechnical men on committees that now is the time in which to make preparations for the winter's load of 1901 and 1902. As a case in point, we would mention Gloucester electrical works, which have only recently been opened, and for which extensions were authorised before the original works were completed. We have had some cuttings from the local Press sent to us containing letters from ratepayers which complain of these extensions on the ground that the plant now installed is much more than able to supply the load at present demanded. Assuming that the figures given are correct, we quite believe that this is so at the present time. On the other hand, we should be very surprised if in the winter days the engineer at Gloucester does not need as stand-by some of the additional plant now on order. One of the curious arguments put forward in this correspondence is that the plant depreciates in value through not being used each day. The argument is that the Corporation is compelled to write off for depreciation and repayment a certain sum per annum, and the writers evidently think that the value of the plant on the books varies with this reduction, and that the market value of the plant must be the same. It would be interesting to ascertain what the gentlemen in question think the value of the plant will be when the whole of the present loans have been repaid. On the same lines it would seem that the Corporation electric lighting station would be worth absolutely nothing because it had been completely paid for, but this is not the view which is usually taken in commercial circles.

BARNSLEY ELECTRICITY SUPPLY WORKS.

Historians have told us very little of the former position held by Barnsley, from which it may be reasonably inferred that the town was of insignificant moment prior to the advent of modern industries. The origin and growth of the place may be said, with sufficient accuracy for all practical purposes, to have been contemporaneous with the opening up of the rich mineral resources of the district

Exterior View of Works, Barnsley.

In the year 1832 Barnsley could boast of but some 8,000 inhabitants, though even then considered an industrial centre of no mean importance. Apart from coal, wire drawing formerly constituted almost the entire trade of the town, but the treatment of flax, bleaching of linen yarns, weaving of linen cloth, foundry and engineering work were also carried on to varying extents, each of these several industries attaining in turn to considerable importance. Nor must the local glass industry be forgotten, Barnsley having in the past gained a high reputation for the manufacture of black glass bottles. Though several of the industries mentioned above have dwindled appreciably, some almost to extinction, the linen-weaving and engineering industries of the town still flourish.

Staff of the Works, Barnsley.

But to the opening up of the famous coal beds in the immediate neighbourhood must be ascribed Barnsley's present-day importance. The well-known Barnsley seam alone averages from 8ft. to 9ft. in thickness, and yields the best steam and house coal in the world. There are also other seams, such as the Silkstone, the Thorncliffe, and Parkgate, which yield both house coal and gas coal in enormous quantities annually. Besides its ample supply of fuel from local sources, the town is well situated for trade generally, and enjoys the advantage of canal navigation, thus being exceptionally favoured as an industrial centre. Strange to say, the country around is also remarkably fertile, its wheat-growing capabilities being famous. From its open position the town has acquired the name "bleak Barnsley"—not "'black' Barnsley," as usually represented, though the latter designation is certainly equally appropriate.

Following the good example set by many other Yorkshire towns, Barnsley has not been slow to avail itself of the advantages to be derived from the practical application of modern science. One of the most recent examples of the town's enterprise is the Corporation electricity works, a supply from which was inaugurated in February of the present year. Before describing these works in detail a few notes

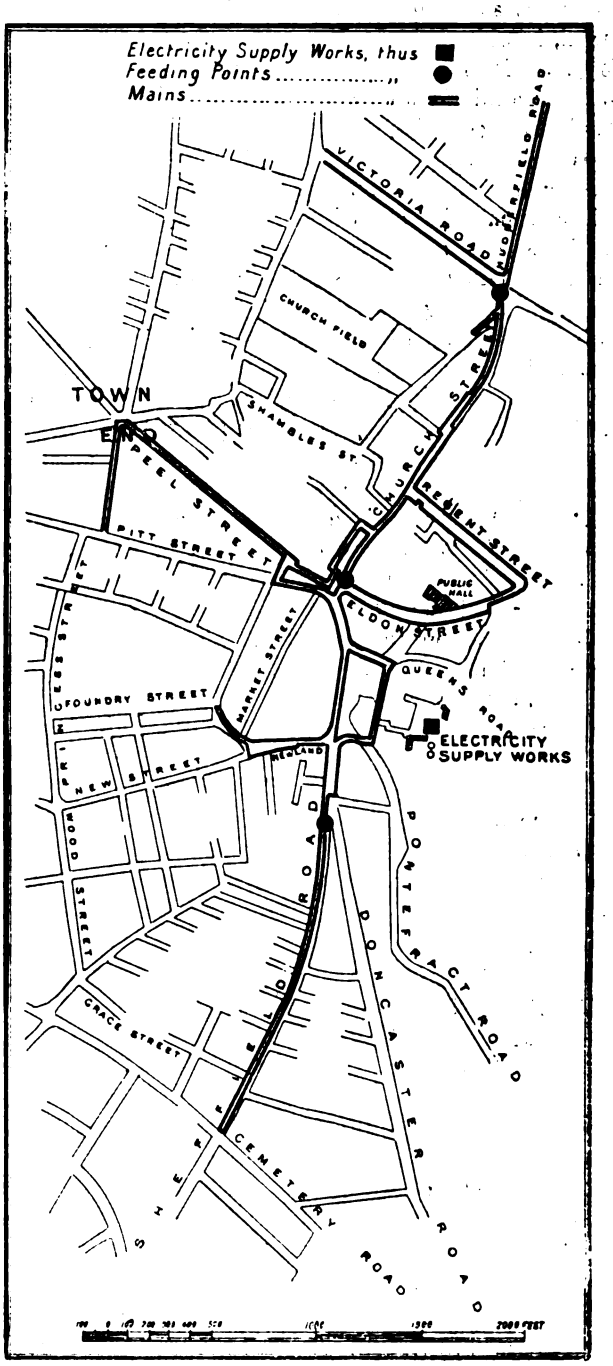

FIG. 1.—Map of Mains, Barnsley.

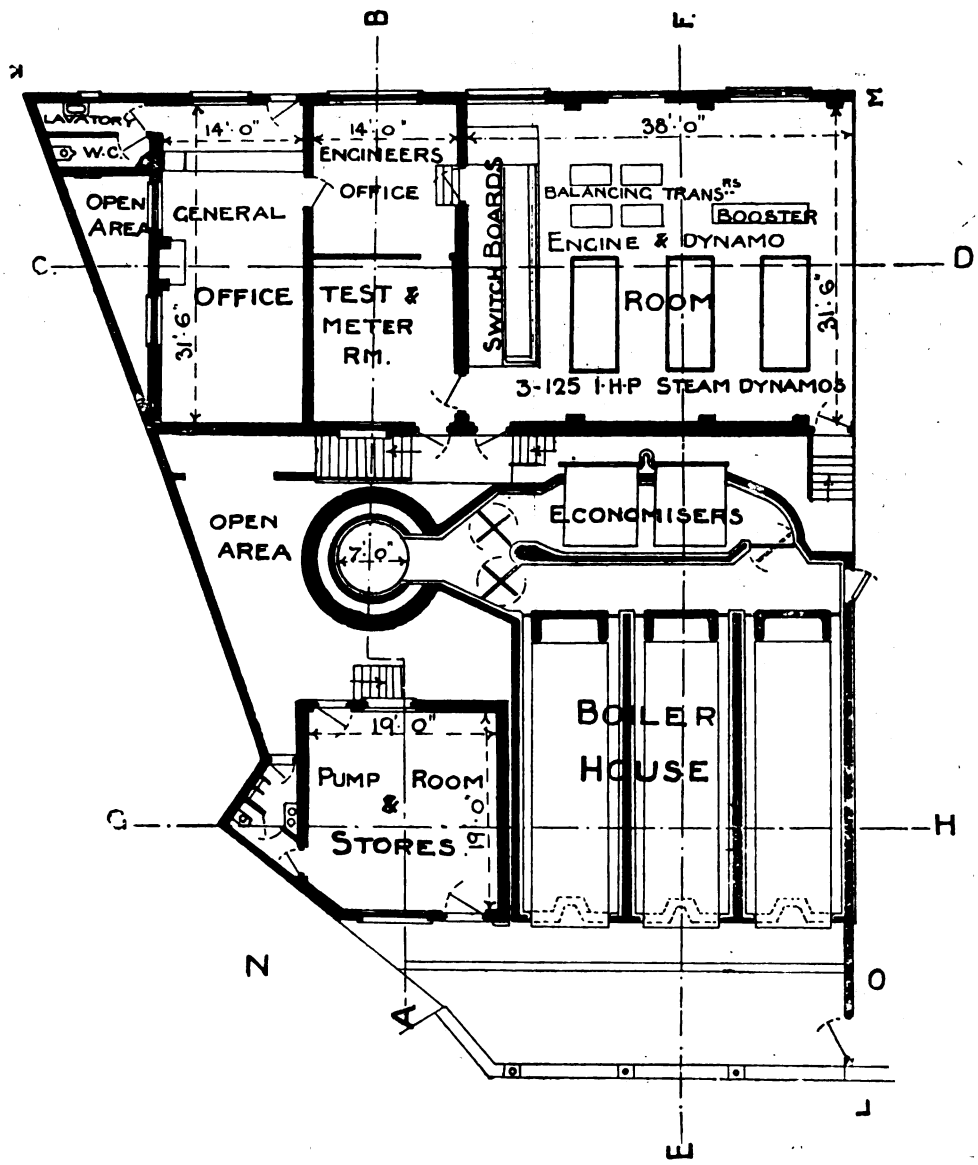
upon the history of the undertaking may be given. In this connection it should be mentioned that for the last 50 years Barnsley has been lighted by means of coal gas manufactured and supplied by the Barnsley Gas Company, whose works were constructed partly by the late Mr. Thomas Hawksley and partly by the late Mr. John Hutchinson and his son, Mr. Walter Hutchinson. But despite the proximity of Barnsley to the above-mentioned source of excellent gas coal, the price of gas as supplied by the Barnsley Gas Company ranges from 3s. 4d. as a maximum to 2s. 10d. as a minimum, subject in prosperous times to a deduction varying from 2½ to 7½ per cent. In justice to the policy of the gas company in charging these

Digitized by Google

high rates, it should be mentioned that the serious leakages from the gas-mains and services caused by broken and drawn joints, owing to the subsidences of the land from the colliery workings, no doubt heavily handicaps their undertaking. In consequence of the prevailing high price of gas, agitations have arisen at various times during the past 20 or 30 years to induce the local authority, formerly the Local Board, now the Barnsley Corporation, to purchase outright the gas company's undertaking with a view to endeavouring to produce and sell gas at a much lower rate than the company do. Nothing, however, so far as the gas supply is immediately concerned has yet come of these efforts, and the result is that the Barnsley Gas Company still flourishes, although the Corporation have at last established an electric lighting



GROUND PLAN

FIG. 2.—Ground Plan of Station Buildings, Barnsley.

plant not only to compete with the gas company, but to supply a light which many people prefer to that yielded by coal gas. As far back as 1882 the Corporation of Barnsley, partly with a view of influencing the gas company to be more liberal by selling gas at a lower price, and partly with the object of ascertaining how far the electric light would be suitable for street-lighting, made an arrangement with the Brush Electric Light Company to run a number of arc lamps in the streets for 22 nights. This experiment was carried out at a cost to the Corporation of £75 The result, however, was not satisfactory, the old arc lamps flickering and sometimes going out, and not being anything like so steady as was expected. The result was that when the arc lamps went out the shareholders in the gas company were jubilant, and when they were brilliant and steady the spirits of those same shareholders descended to so low an ebb that some of them sold their shares, believing the days of coal gas to be at an end.

However, from the year 1882 to the year 1888 no further progress was made in Barnsley towards the establishment of electric light, but between the years 1889 and 1892 no less than five reports were presented to the Council by Mr. J. Henry Taylor, M.I.C.E, the present borough surveyor, each of which was endorsed and approved by the Council, and it was duly recommended that the electric light be installed within the borough. The first report was practically an elementary treatise upon electricity and electric lighting for the instruction really of anyone interested at that time in electric lighting, but the later reports were of a more intricate and advanced character, going into estimates of probable capital outlay, revenue, and working costs, etc. The result of these reports was that in 1890 the Corporation, assisted by Mr. A. Bromley Holmes, of Liverpool, the late Dr. John Hopkinson, of Westminster, and the borough surveyor (Mr. Taylor) obtained a provisional order for electric lighting within the borough of Barnsley, and immediately afterwards invitations were issued to several companies to send in proposals for the erection of plant, laying of mains, and the running of an electric light station for the town and district. Proposals or tenders were received from the following firms—viz, New Gulcher Company, Manchester Edison-Swan Company, Messrs. Laing, Wharton, and Down, National Electric Supply Company, and the Westinghouse Electric Company. Advised by Mr. Bromley Holmes, the Council decided to accept the tender of the Westinghouse Electric Company

Digitized by Google

for the installation of a plant and the laying of the necessary mains, for the sum of £17,800; the buildings being estimated to cost a further £5,000, making a total estimated expenditure of about £23,000. Unfortunately, about this time financial troubles developed in the United States, where the Westinghouse Company's works were chiefly established, and this company were forced to withdraw their tender, leaving the Corporation again without any immediate prospect of having an electricity supply

S. E. BASTOW.

established. In order, however, to keep up the good feeling towards the electric lighting of the town, and to obtain further information, the Park and Lighting Committee visited various towns in the United Kingdom which had already adopted electric lighting, in the years 1891 and 1892, and presented further reports to the Council. As a result, the Town Council in 1898 appointed Mr. A. Bromley Holmes, M.I.C.E., and Mr. Thomas L. Miller, M.I.C.E., joint engineers to report upon a scheme of electric lighting for the town, but Mr. Bromley Holmes having just then been appointed chief electrical engineer to the Liverpool Corporation, and being practically debarred thereby from private practice, the work thus devolved upon Mr. Miller, who in March of the same year reported in favour of a three-wire direct-current system, with a pressure at consumers' terminals of 230 volts, the estimated capital cost for the establishment of a plant with cables complete for 6,000 8-c.p. lamps, including £3,000 for buildings, being £23,322. 15s., which in the application to the Local Government Board was increased to £25,000. The report being accepted, tenders were invited to the specifications of Mr. Miller for the plant, machinery, and foundations, and Mr. Taylor for the buildings, contracts for the work being placed as follows:

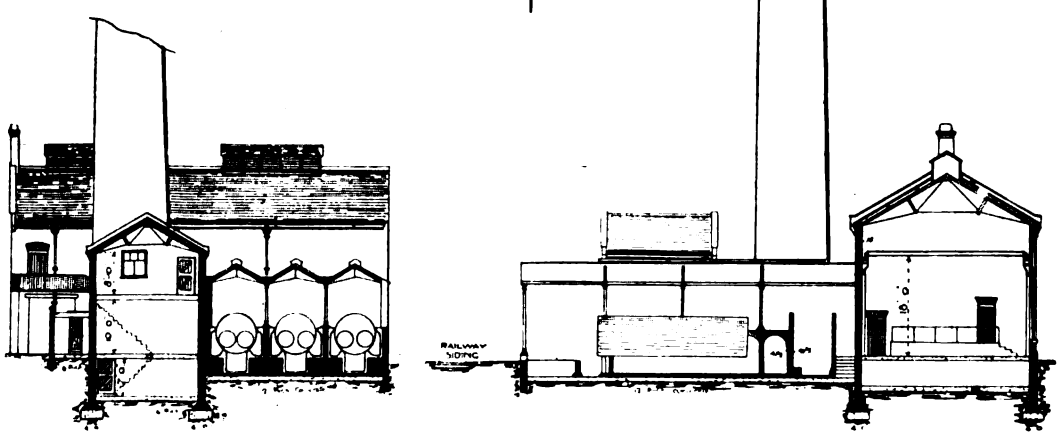
W. Arnold and Co., boiler-house plant	£3,260	0	0
Johnson and Phillips, electrical equipment	7,770	0	0
Pritchett and Gold, batteries	1,319	0	0
British Insulated Wire Company, mains	6,322	4	2
James K. Taylor and Sons and George Mellor respectively, buildings and chimney	3,080	19	8

which, with £1,442. 1s. 2d. for meters, indicators, and engineer's fees, amounts to £23,194. 5s., or £128. 10s. below the original estimate.

Owing, however, to the numerous applications for supply from the time of the commencement of the works to the spring of last year, it was decided in July, 1899, to extend the generating plant and make application to the Local Government Board for sanction to expend a further sum of £3,000, making £28,000 in all, and a supplementary order was placed with Messrs. Johnson and Phillips for a 150-kw. steam dynamo, the cost of which, including foundations, extensions to piping and switchboard, and engineer's fees, amounted to £2,342. 11s. In addition to this, the mains were extended at a cost of £130. 17s. 7d. The accepted tenders for the original scheme and extensions, excluding buildings, amounted to £21,533. 1s. 9d., but the final accounts, including all extras, amounted to but £21,531. 9s. 9d., or £1. 12s. less than the tenders originally accepted. The total cost of the works, including buildings, engineer's fees, etc., has been £26,552. 1s., or £70 78 per kilowatt installed. Regular supply was commenced in February of the present year, and on July 18 last the number of consumers on the books stood at 121, with an aggregate of 8,342 lamps of 8 c.p. or their equivalent connected to the mains.

Most, if not all, of the members of the Council who in years gone by fought and worked hard to get the electric light introduced into the town have passed out of the Council, notably ex-Alderman Blackburn and ex-Councillor Isaac Haigh, who both took a very active and intelligent part in advocating the introduction of the new light. It should be a great satisfaction to them to know that chiefly through their labours the electric light has at last become a reality in the town. The constitution of the present Parks and Lighting Committee is as follows: Councillor Walter Brady, J.P. (chairman), Aldermen T. Wilkinson, J.P. (mayor), C. Wray, J.P., W. Holden, Councillors W. Atkinson, W. H. Carter, J. Charlesworth, W. Foulstowe, R. W. Maddison, and J. S. Rose. Mr. Henry Horsfield is the town clerk.

As has already been mentioned, the constructive electrical engineer to whose plans and specifications the works have been equipped throughout has been Mr. Thomas L. Miller, M.I.C.E., of Liverpool, while the architect for the buildings was Mr. J. Henry Taylor, M.I.C.E., the borough surveyor.



SECTION ON LINE C.H. SECTION ON LINE E.F.

FIG. 3.—Section of Station Buildings, Barnsley.

The borough electrical engineer, who acted as resident engineer during the construction of the works, is Mr. Stephen E. Bastow, his chief assistant being Mr. E. A. Barker. Under the able management of Mr. Bastow the undertaking has continued to make rapid progress, and bids fair to become a complete financial success, besides being a benefit to the town in other respects. With regard to the possibilities of the undertaking, it may be mentioned that Barnsley possesses some 42,000 inhabitants, the area and ratable value of the town being respectively 2,386 acres and £88,000. The compulsory area of supply comprises some three miles of streets, constituting what is practically the centre of the town. A good field is offered for motors, the linen mills in the town being large users of power. We understand there is probability of two large mills connecting up to the Corporation's supply mains, an aggregate of upwards of 200 h.p. in motors being in prospect. The policy of the Corporation has been to anticipate the demand by extending the supply mains to probable large consumers of power. The shops, hotels, and private residents are availing themselves of the supply freely. Further, there is every prospect of a traction load being added at no very distant date. Some months ago the Corporation entered into an agreement with the British Electric Traction Company, whereby the latter are to construct tramways in the town within the period of three years, the Corporation to have the option of purchasing the same after 12 months' working. The proposed lines aggregate a length of about five miles. The agreement with the British Electric Company further provides that the necessary energy for working the lines shall be taken from the Corporation, a minimum consumption of 200,000 units per annum to be charged at the rate of 1½d. per unit, with a reduction of ·1 of a penny for every additional 75,000 units consumed. In anticipation of this load, traction type generators have been put down, which serve, meanwhile, for the ordinary requirements of the supply. A small scheme of public street-lighting by means of arc and incandescent lamps has already been adopted. This provides for 15 arc and 30 incandescent lamps, but represents only a small portion of the street-lighting scheme to which it is ultimately proposed to give effect. The present street-lighting by means of gas is managed by the Corporation so far as lamps, mains, and general supervision are concerned, the lamp standards, mains, and accessories being Corporation property. The necessary supply of gas is, however, obtained from the gas company. Electrical energy for lighting purposes is supplied to the ordinary consumer on Wright's maximum demand system, 7d. being charged per unit for the first hour and 3d. afterwards, while to consumers taking more than 10,000 units per annum a preferential rate of 7d. and 2d. is conceded. For power 2d. per unit is charged.

The site upon which the works stand was formerly a part of the manor of Barnsley, and was recently purchased from Sir Hickman Beckett Bacon, Bart., and others, for the purposes of a highways and waterworks depot, and for market accommodation. As will be seen from the accompanying map of the main (Fig. 1), its situation relative to the area of supply is very central. Apart from the latter advantage, the facilities which the site offers for economically coaling the station are also good, a coal siding from the Great Central main line hard by running right into the station yard. There are collieries within a mile of the station, but the present supply is obtained from pits situated at a distance of about three miles. With the coal trade in its normal condition we understand that suitable coal may be obtained at the pit's mouth at from 4s. to 4s. 6d. per ton, but the prevailing abnormal conditions have involved such an advance of prices even at this great centre of supply that 10s. per ton delivered at the works was the rate charged at the time of our visit some months ago, though doubtless local prices have suffered still further increase since then. Compared with prices ruling elsewhere, the price mentioned is, of course, extremely moderate; but, on the other hand, very high when local conditions are taken into consideration. The site of the station, in fact, is situated right over a coalfield, and surface coal was actually met with in excavating for the chimney shaft, while there is any amount of the commodity lower down. Not many stations enjoy such close proximity to a possible source of coal supply. In the event of a serious coal strike and consequent shortage of the supply, it seems quite within the realms of possibility

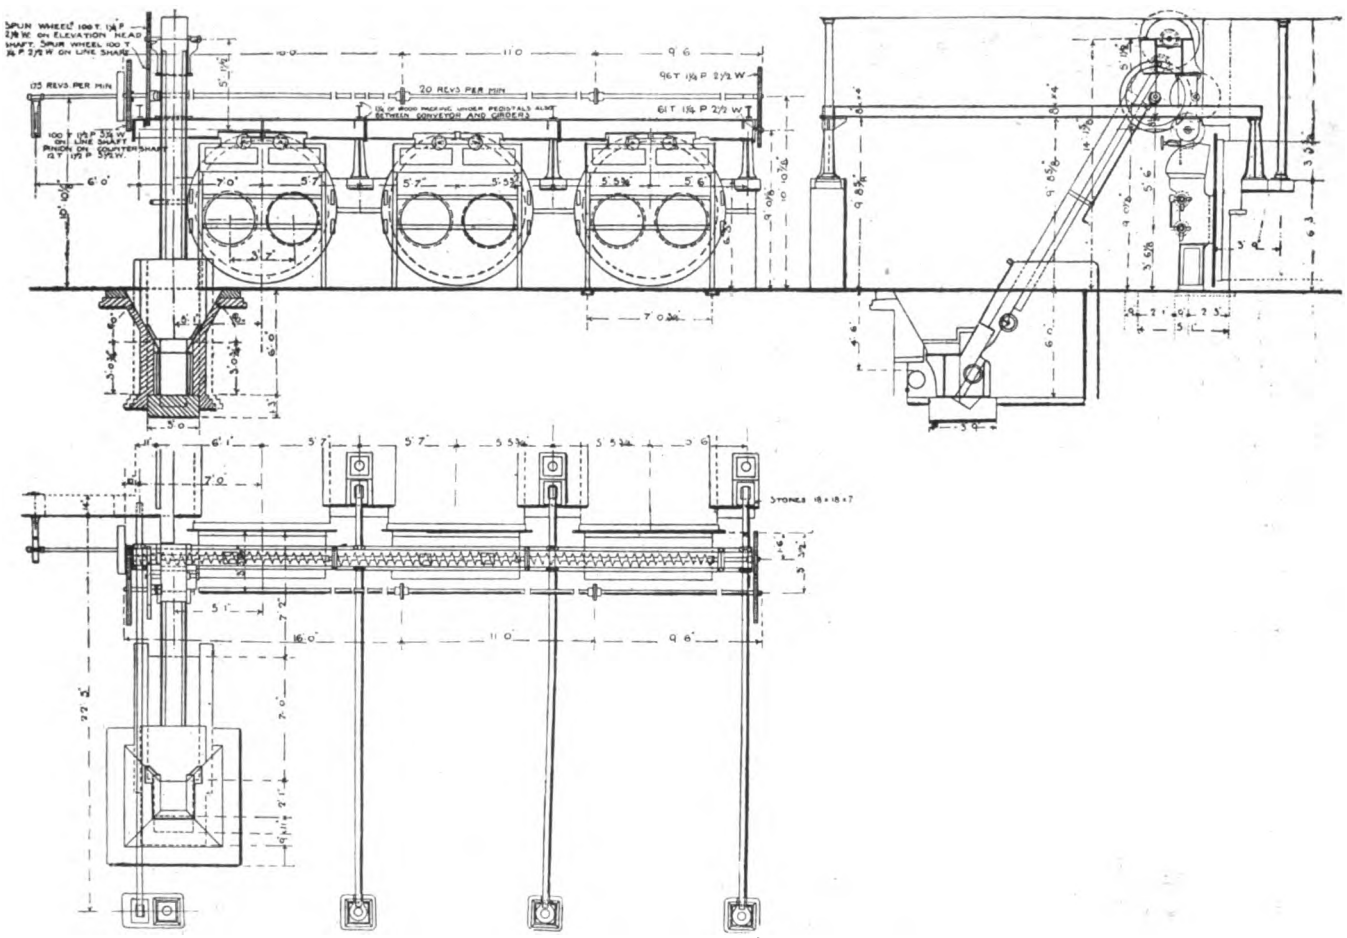

FIG. 4.—Arrangement of Coal Elevators and Conveyors, Barnsley

Digitized by Google

that the station's depleted bunkers might be replenished from the resources of the site, though it would present a curious spectacle to see the staff busily engaged in winning fuel for the immediate requirements of the station. As a set off against the advantages enumerated above, it must be mentioned that no water for condensing purposes is available upon the site selected—a serious drawback to a modern plant of considerable capacity.

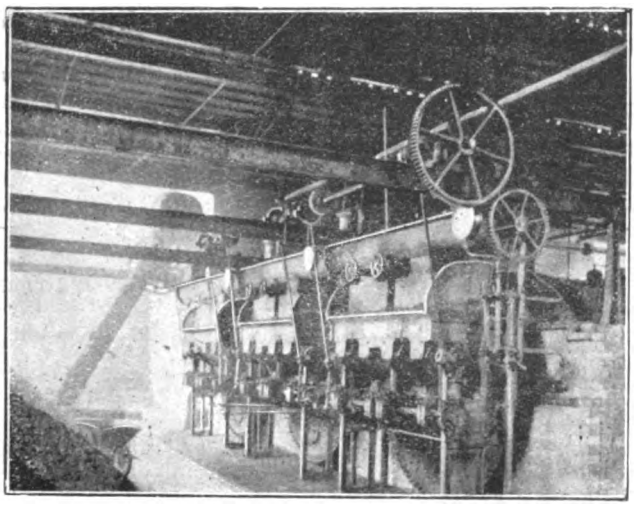

FIG. 5.—View of Boilers fitted with Mechanical Stokers, Barnsley.

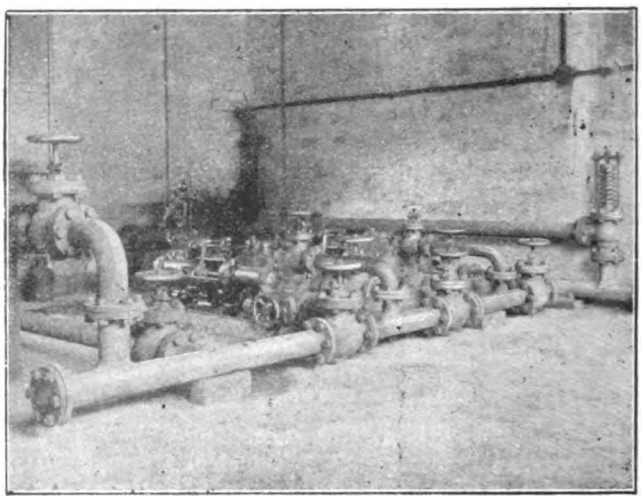

FIG. 6.—Interior of Pump Room, Barnsley.

The generating station buildings comprise a commodious engine and dynamo room, boiler-house, test and meter room, accumulator-room, pump-room and stores, engineer's office, and the usual general offices, etc. For the principal dimensions of these several departments we would refer the reader to the accompanying ground plan and sections (Figs. 2 and 3). The chimney shaft, better shown in the latter figure, has a height of 150ft, and an internal diameter at the base of 7ft. The foundations are of concrete, no piling being used. Great compactness, as will be seen, characterises the general design of the buildings, which are in every way eminently adapted to their purpose, the general arrangement adopted being calculated, moreover, to afford the maximum facilities for future extensions.

The boiler-house equipment includes at present three Lancashire boilers designed for a working pressure of 160lb. per square inch. Each boiler is 28ft. long and 7ft. 6in. diameter inside the outer ring of plates, and possesses two flues, each 3ft. diameter at the furnace end, tapering to 2ft. 6in. diameter at the back end, each flue being fitted with four conical cross tubes. The boiler mountings are of Hopkinson's make throughout. Before leaving the contractor's works each boiler was subjected to a pressure test of 260lb. per square inch. Mechanical means are provided for firing the boiler furnaces in the form of Vicar's mechanical stokers, driven by an 8-h.p. electromotor. The details of the system of elevators and conveyors, with the gearing necessary for driving the same, are shown in Fig. 4, while in a reproduction of a photograph of the apparatus in position (Fig. 5) the mechanically-fed hoppers of the stokers are also shown. The gear is capable of serving six boilers similar to the ones now installed. The coal store is situated immediately in front of the boilers, and, as required, a supply of the fuel is fed into the elevator pit (shown in Fig. 4), from which the buckets of the elevator raise it to the conveyor, which latter in its turn feeds the hoppers of the mechanical stokers. Simplicity and efficiency characterise the arrangement, which ensures minimum labour in handling the coal after it has been unloaded from the coal trucks into the coal store. One of Green's patent fuel economisers is provided in a by-pass of the main flue, as shown in Fig. 2. This economiser, which

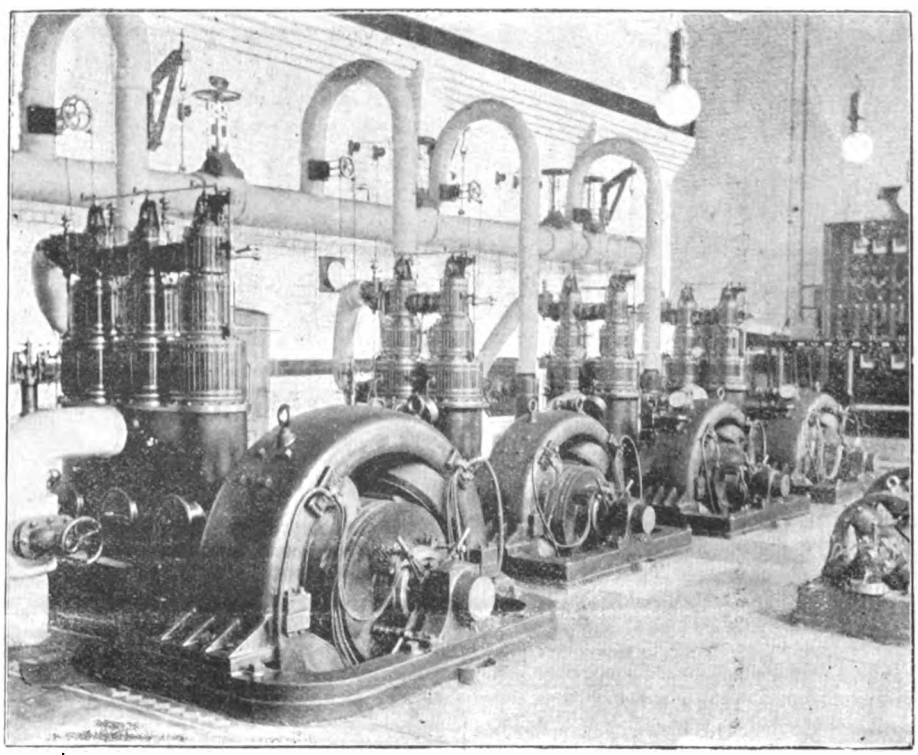

FIG. 7.—Engine and Dynamo Room, Barnsley.

Digitized by Google

is designed for a working pressure of 160lb. per square inch, consists of 192 tubes, each 9ft. long and about 4in. diameter inside. The scrapers are driven by an electromotor. Wing dampers and dampers in the flues serve to direct the waste gases from the boiler furnaces either through the economiser or to the chimney direct. The boiler feed pumps, situated as shown in Fig. 2, are of the Worthington type and make, and two in number. Each is capable of delivering 1,500 gallons of water per hour against the full boiler pressure of 160lb. per square inch. The feed pumps (Fig. 6) are arranged to draw from the hot-well, a separate suction pipe being used for each pump, with connections to either the feed tank or the low-pressure water-main. The delivery pipes are arranged so that the discharge from either pump may be taken direct through feed-water heater, and thence through the economiser to the boilers, or else through the heater and direct to the boilers, or past both the heater and economiser direct to the boilers. A Kennedy water-meter, reading to 10 gallons, is fixed in the line of delivery pipes to the heater, which latter is by Royles, of Manchester, and capable of raising the temperature of 2,000 gallons of water per hour from 55deg F. to 200deg. F. It may also be mentioned that the feed pumps are arranged to take steam from either side of the main range of steam-piping, and to exhaust into the main exhaust pipe to atmosphere, and provide a duplicate feed.

With regard to the steam-piping, a "ring" system with isolating valves has been provided. The pipes in the main ring are 8in. in diameter, being slung from the engine-room and boiler-house walls by means of rods and slings, as shown in Fig. 7. Hopkinson's isolating valves are employed. The main exhaust pipe, of cast iron, is 16in. in diameter, and arranged to lie in a chase formed at the side of the engine foundation. This pipe is connected to the heater above mentioned, and arranged with a by-pass, so that the exhaust steam may be taken through the heater, or direct to the atmosphere, the heater in the latter case being cut out. The clear-water drains from the steam-pipes, etc., are taken to a brick feed tank situated at the side of the chimney shaft, and from which the feed-pump supply is drawn. This tank, it may be mentioned, is covered in and provided with a duplicate supply from the Corporation mains.

We now come to the engine-room equipment, which includes three steam-driven 75-kw. sets, besides the 150-kw. extension set previously mentioned. The engines

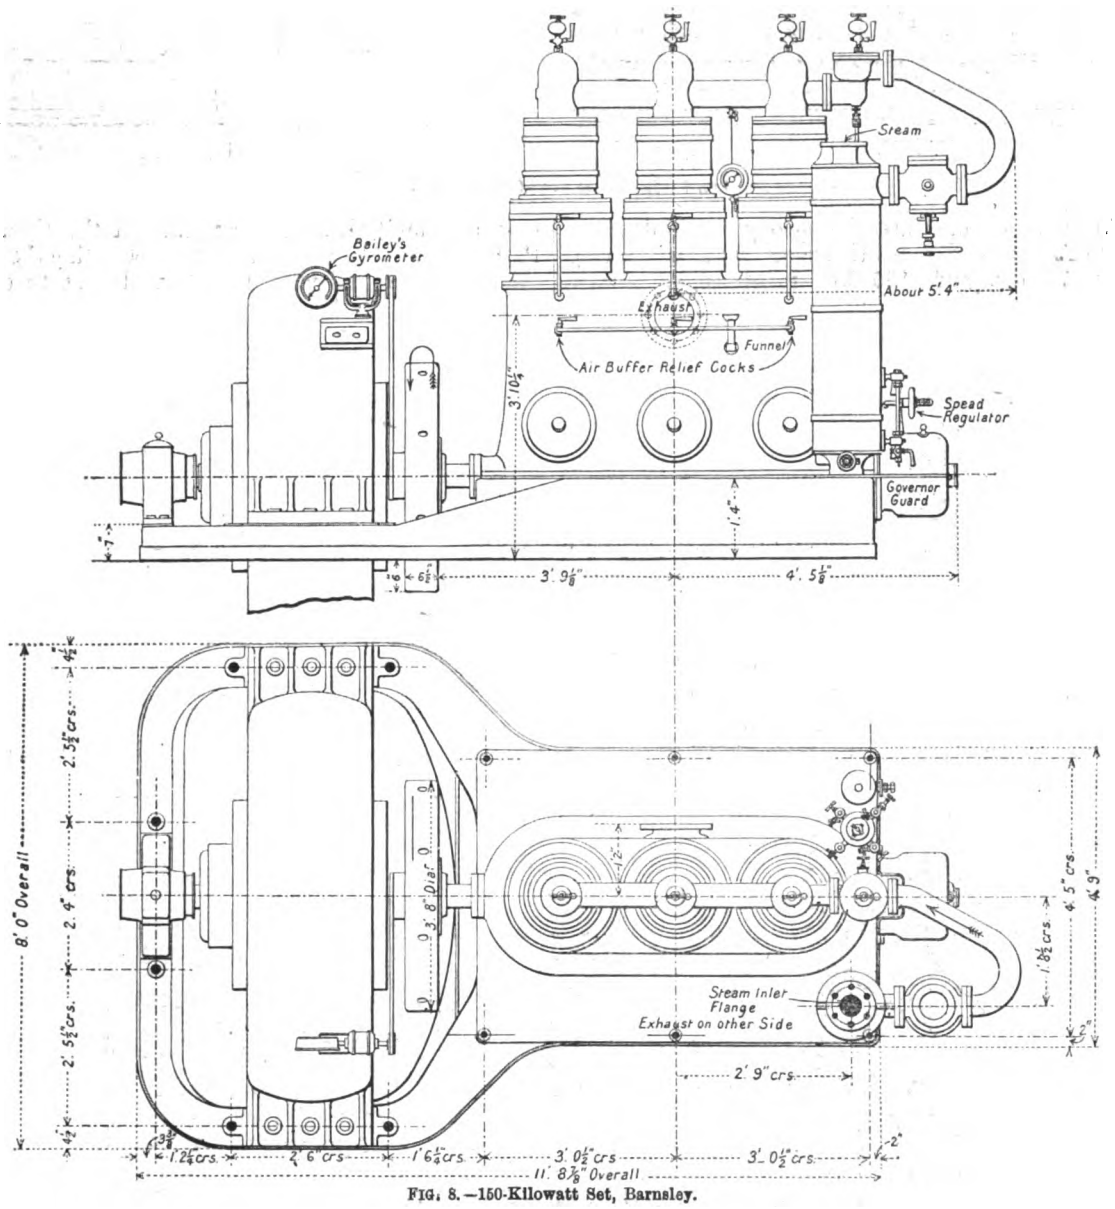

FIG. 8.—150-Kilowatt Set, Barnsley.

driving the 75-kw. generators are of the Willans compound non-condensing type, indicating 100 b.h.p. each when running at 450 revolutions per minute with a steam pressure of 150lb. at the stop valve. They are fitted with automatic expansion gear for regulating the cut-off when running on the anticipated tramway load, and further specially strengthened in order to better adapt them for supplying energy for tramway purposes. Corresponding parts of the engines are interchangeable, the great advantage of which arrangement has been practically illustrated in scores of cases. It was specified that the water consumption of each of these engines at full load should not exceed 26lb. per brake horse-power per hour.

The larger engine is of what is known as Willan's 3 H/s size. It indicates 250 h.p. when running at 380 revolutions per minute with a steam pressure of 150lb. at the stop valve. This engine has also

Digitized by Google

been fitted with automatic expansion gear, and will be used for driving the trams. Fig. 8 shows a plan and elevation of this set, with the principal dimensions. All four engines are direct-coupled to Johnson and Phillips's multipolar traction-type dynamos, giving outputs of 75 kw. and 155 kw. respectively. These dynamos, as will be seen on referring to Fig. 7, are four-polar, and each is arranged to stand on the same bed-plate as the engine driving it. Being required for traction work the machines are, of course, shunt-wound, and have drum armatures. Each of the smaller machines is capable of an output of 75 kw. at an E.M.F. of 460 volts, and is wound to give any E.M.F. between 460 and 520 volts when running at the specified speed of 450 revolutions per minute, the regulation being effected by means of resistance coils and multiple-contact switches in the shunt circuit. Particular attention was given in constructing the armature, the parts being specially strengthened so as to enable the armature to better withstand the stresses brought to bear on the dynamo when used for supplying energy for tramway purposes. It was specified that the temperature of any accessible part of the dynamo should not rise above 60deg. F. above the temperature of the surrounding atmosphere during a six hours' continuous run at full

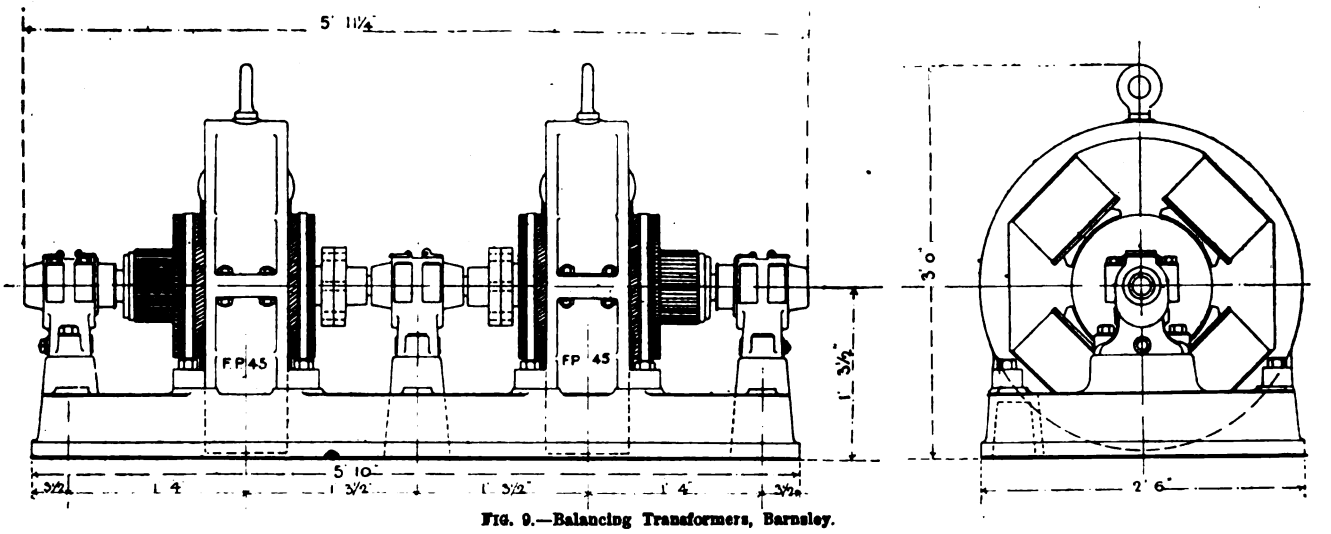

FIG. 9.—Balancing Transformers, Barnsley.

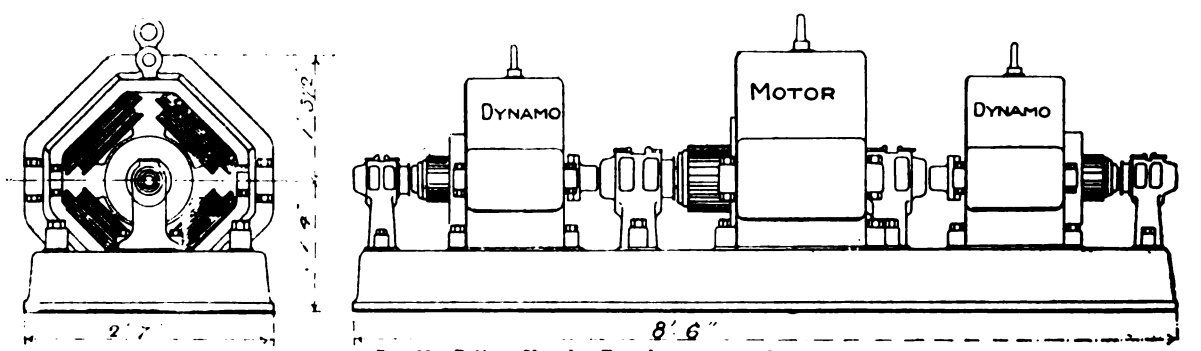

FIG. 10.—Battery Charging Transformers, Barnsley.

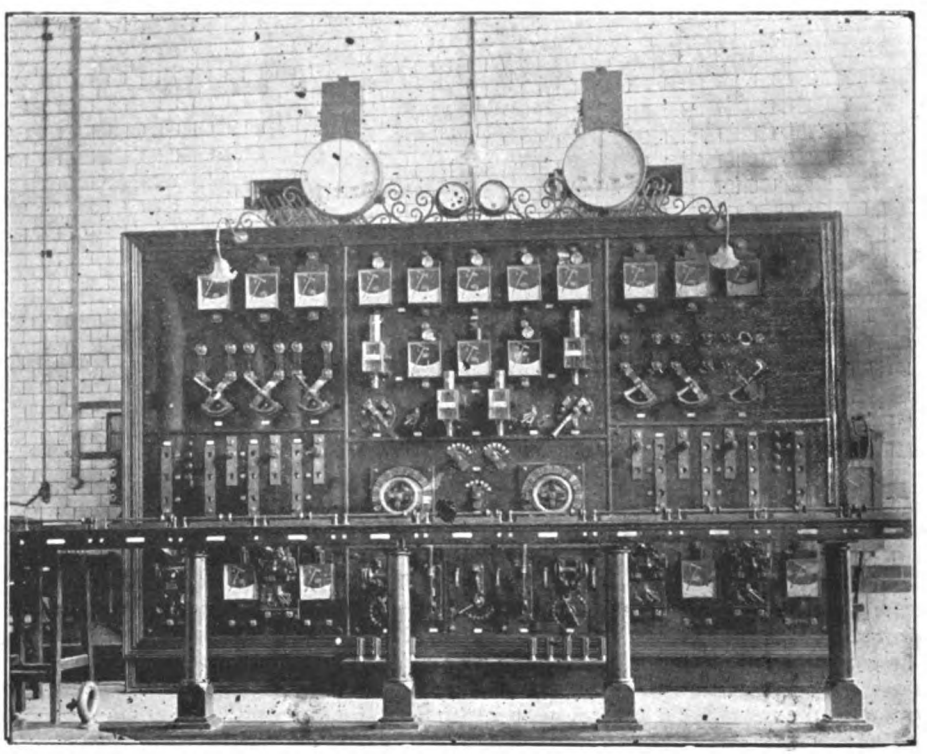

FIG. 11.—Switchboard, Barnsley.

Digitized by Google

load; also, that the combined efficiency of each set, or the ratio of the electrical horse-power at the dynamo terminals to the indicated horse-power developed by the driving engine, should not be less than 81 per cent. The engine-room equipment also includes two balancing transformers. As shown in Fig. 9, each of these transformers consist of two balancing armatures directly connected and working in separate fields. The transformers are connected across the outer mains of the three-wire system at the switch-board omnibus bars, and also to the middle wire. These balancers are each capable of balancing the whole system at any load, so that when there is a current of 75 amperes in either direction in the middle wire, the difference of E.M.F. at the feeding points between the two sides of the system shall not exceed four volts. Two battery-charging transformers or boosters (Fig. 10) are further provided, each of which is capable of an output of 130 amperes at 75 volts. These boosters are designed and arranged to give an E.M.F. of from 10 to 75 volts on open circuit, and also to be capable of running with any current from 0 to 130 amperes at any pressure up to 75 volts. The arrangement of the plant in the station in shown in Fig. 2, except the 155-kw. extension set, which latter is, however, shown in the foreground in Fig. 7.

The switchboard, which was supplied by Messrs. Johnson and Phillips, is erected upon a platform, as shown in Figs. 7 and 11. It is arranged for the connection of four dynamos, four feeders, two batteries, two balancing transformers, and two boosters. The middle wires from the feeder points are brought back and connected in parallel at the station, one middle wire connection only being made on the switchboard. The board consists of three slate panels carried in iron frames and neatly cased on the outside with varnished teak. The instruments and apparatus in connection with the batteries, the balancing transformers, and the boosters are arranged on the centre panel, together with the voltmeters and their switches, while the instruments and apparatus on the negative side of the dynamos and feeders are arranged on the right-hand panel, and those on the positive side on the left-hand panel. Connections to the dynamos are taken from the bottom of the board, and the connections to the feeders from the top of the board. It will be unnecessary to enumerate in detail the instruments, etc., in the circuit of each dynamo and feeder. Ample provision for the future extension of the board has been made, and also for putting the same in connection with the traction switchboard yet to be installed. The centre panel is provided with a battery emergency switch for cutting the battery out of circuit if required. A single-pole throw-over switch enables the battery to be placed either on to the booster circuit to be charged, or on to the mains, as may be required. All resistance coils are placed below the switchboard platform. The switchboard connections are clearly shown in Fig. 12. Before leaving the engine and dynamo room brief mention may be made of the overhead travelling crane, which is capable of lifting eight tons as the ordinary working load. All motions are worked from the ground by means of ropes. A specially

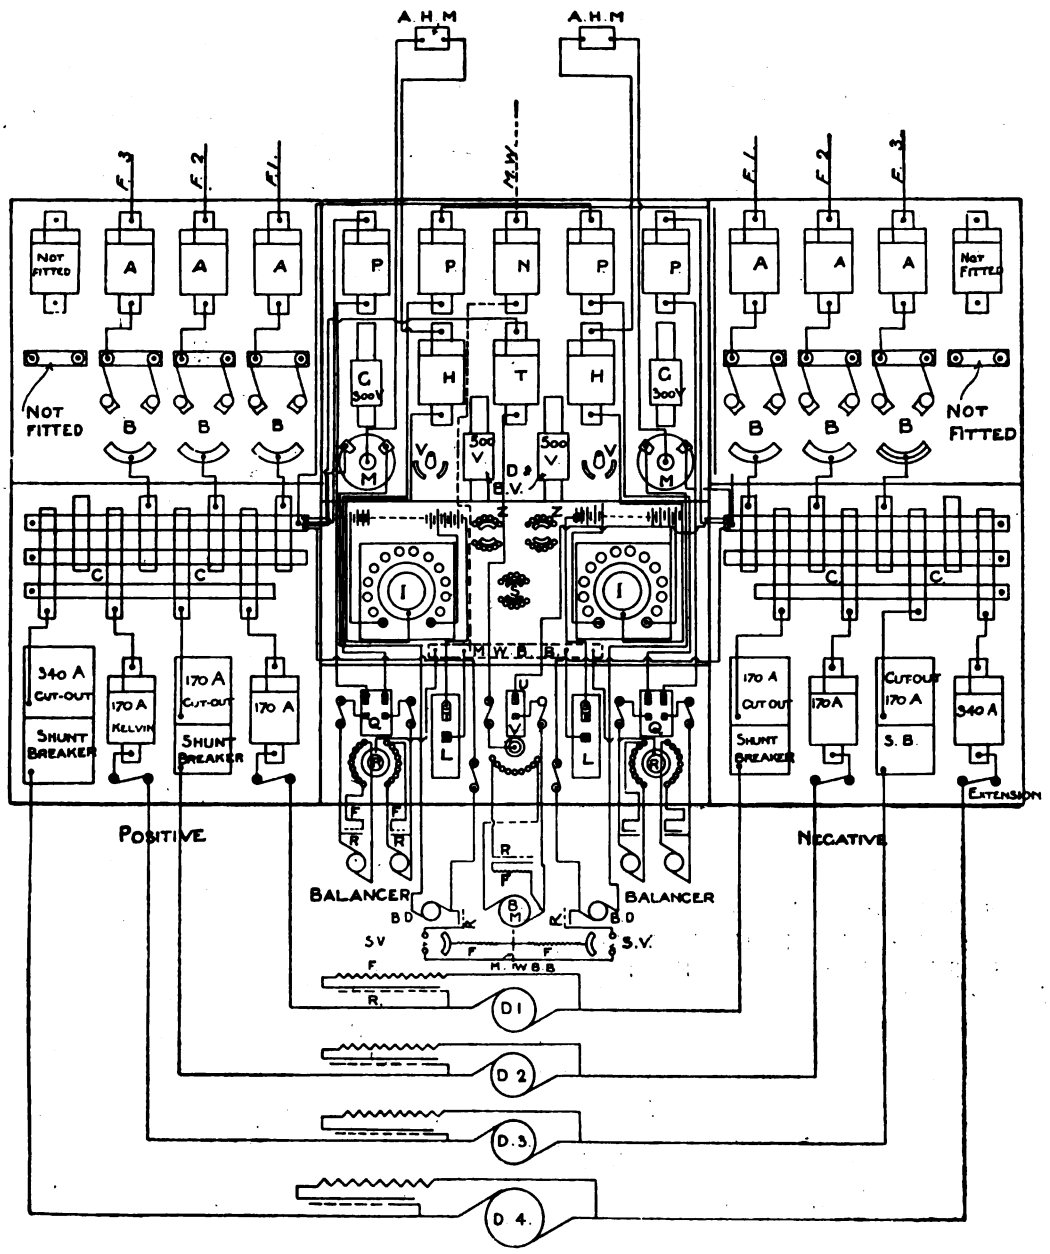

Fig 12.—Diagram of Switchboard Connections, Barnsley.

Digitized by Google

quick lift is provided for loads of one ton and under. The artificial lighting of the engine and dynamo room is provided by Lunar arc lamps.

With reference to the accumulators, it may be mentioned that these were supplied by Messrs. Pritchetts and Gold. The battery (Fig. 13) consists of 260 cells in glass boxes, each cell containing 23 plates, 9in. by 9½in., the positives being ⅛in. and the negatives ⅛in. thick. Both positive and negative plates were formed by the Planté process, and are of the make'rs standard type. The battery is divided into two halves for feeding the three-wire system, and the capacity is 500 ampere-hours at 100 amperes discharge, and 300 ampere-hours at 300 amperes discharge, the E.M.F. per cell at the end of either discharge being not less than 1·86 volts. The cells are mounted on wood trays with oil insulators, and are erected on substantial wood stands in two tiers. The connections between the rows and tiers and between the battery and regulating switches are made with bare copper rod supported on porcelain insulators.

There now remains only the distributing network of mains to deal with. This, together with the feeders, is on the three-wire single-cable system. The whole of the cables were manufactured by the British Insulated Wire Company, and are of their paper-insulated lead-covered type, laid in earthenware troughs filled in solid with bitumen. Three sets of feeders—·5 square inch, ·2 square inch, and ·5 square inch section—leave the electricity

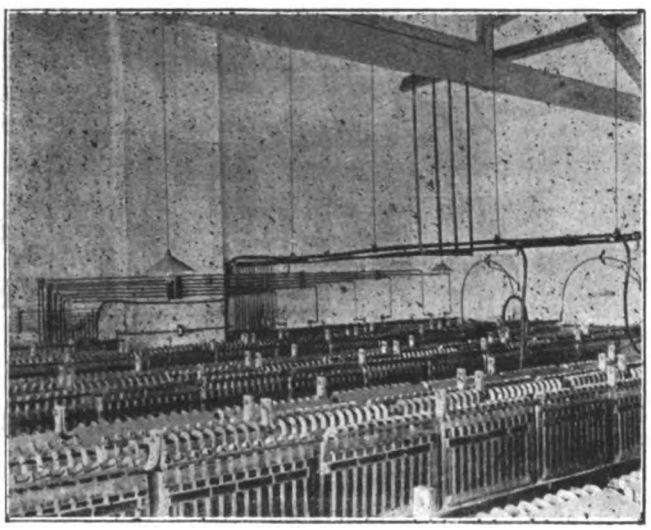

FIG. 13.—Battery-Room, Barnsley.

works, and supply feeding points in Huddersfield-road, Market-hill, and Sheffield-road, as shown in Fig. 1. To each of these feeding points a three-core pressure cable is laid along with the feeders from the station switchboard. The distributing cables are of

(·25 ·15 ·25) (·15 ·10 ·15) (·10 ·06 ·10) square inch section, and supply approximately six miles of streets. Cast-iron junction boxes, placed in brick inspection pits, are spaced over the area of supply, and the distributing network is so arranged as to allow of ample extension. House services, laid on the British Insulated Wire Company's solid system, are connected to the distributor cables by means of special boxes having glands cast to fit into the earthenware troughs.

The street-lighting immediately provided for consists of 15 10-ampere arcs and 30 16-c.p. incandescents, the latter being attached to the arc lamp-posts in pairs. The arcs are to be connected four in series across the outers of the three-wire system. Messrs. Crompton and Co. have secured the order for these lamps. It is proposed to largely extend the system of street-lighting by means of arcs and incandescent lamps at some future date.

It will have been gathered from the above that Barnsley has obtained a very compact and efficient plant at a cost per kilowatt installed which, having regard to the thorough manner in which the work has been done throughout, and the ample provision made for future developments of the undertaking, must be adjudged moderate. Great forethought is evidenced by the design of the station, whereby a plant has been secured which will serve to suit equally well the requirements of a lighting, traction, or ordinary power load.

In conclusion, we have to thank the consulting engineer, Mr. Thomas L. Miller, for his courtesy in according us facilities for collecting most of the information given above.

THE ELECTRIC LIGHTING OF THE CITY OF GLASGOW.

Like London, Glasgow was the scene of some very early attempts at electric lighting. The first one was the lighting of Hengler's Circus by means of the Jablochkoff candle, but the writer cannot fix the date. The next attempt was in 1879, when the British Electric Company illuminated St. Enoch Station with arc lamps, using Gramme dynamos, and Messrs. Crompton and Co., who, about the same time, installed the electric lighting plant in the Queen-street Station of the North British Railway Company. It must be very gratifying to Messrs. Crompton to see their latest type 750-kw. 12-pole dynamos in the new station, in view of the machines which for so many years did such satisfactory work, although built over 20 years ago, in the days when the magnetic principles of dynamo design were not by any means well understood.

About the same time that Messrs. Crompton erected the Queen-street Station plant, Messrs. Muir and Mavor laid down a temporary plant to supply electrical energy for lighting Glasgow Post Office, which was the first post office in the kingdom to be lighted by electricity. Eight years later Messrs. Muir, Mavor, and Coulson proceeded to lay down a high-tension alternate-current system, 2,400 volts, with transformers on consumers' premises transforming to the then orthodox pressure of 100 volts. Seeing the possibilities of electricity supply in Glasgow, Messrs. Muir, Mavor, and Coulson applied for a provisional order for electric lighting, so also did the Corporation, and eventually the private company withdrew in favour of the civic authorities, who afterwards purchased the company's undertaking for £15,000. A remarkable feature about the private company's system was their early recognition of the value of the maximum demand method of charging for energy, the charge being a fixed sum per unit with discounts as the consumption exceeded 300, 500, 1,000 or 1,500 hours maximum demand per annum.

On March 1, 1892, the municipality took possession of the company's undertaking, but as the Board of Trade would not permit the supply of electrical energy by means of overhead cables beyond August, 1893, the city authorities had to lose no time in getting their new station in working order. Acting on the advice of Lord Kelvin, a three-wire low-pressure continuous-current system was adopted, and Prof. A. B. W. Kennedy was appointed consulting engineer to prepare a general scheme. The result was the Waterloo-street station equipped with dry-back marine-type boilers, Willans engines, and Latimer Clark and Crompton dynamos, with a separate street-lighting plant consisting of belt-driven Brush arc-lighting dynamos. All this time the electricity undertaking was managed by the gas engineer, Mr. Wm. Foulis, M.I.C.E., with Mr. Wm. Arnot acting as resident engineer. In 1896, however, the city authorities saw that, to enable the natural process of evolution to take place, the electricity undertaking should be independent of the gas department. Development was now more rapid, and it soon became apparent that greater feeder capacity would be as necessary as generator capacity. To improve the load factor of the station, and relieve the feeders during the hours of maximum demand, two temporary accumulator sub-stations were placed at almost the two extreme ends of the distributing system; these were charged during the early hours of the morning or middle day, and discharged at the peak of the load, a plan which worked well for quite a long time. Meanwhile the committee, advised by their engineer (Mr. Wm. Arnot, M.I.C.E.), turned their attention to the acquisition of sites for two new generating stations, one on the north and the other on the south side of the city, and arrangements were made to erect the necessary build-

Digitized by Google

ings. About this time Mr. Arnot resigned to carry on business as a consulting engineer, and a few months later Mr. W. A. Chamen, of Messrs. Crompton and Co., was appointed resident electrical engineer, and the construction of the new stations pushed rapidly forward under his able supervision.

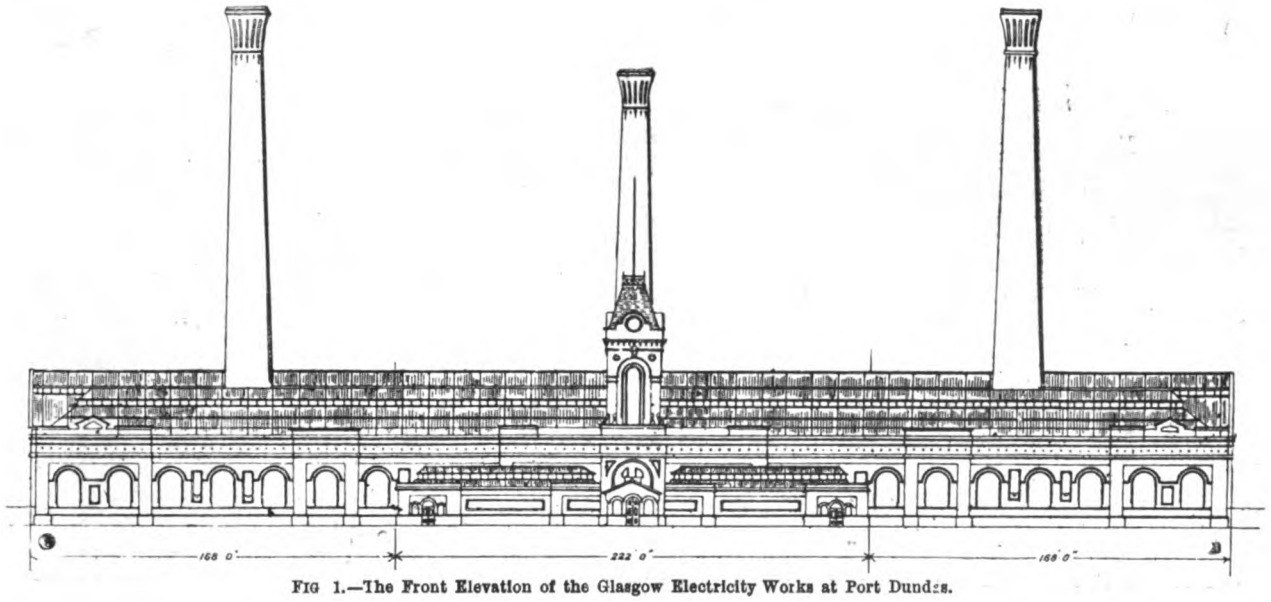

FIG 1.—The Front Elevation of the Glasgow Electricity Works at Port Dundas.

The practical results are seen in the stations which were formally opened on Thursday week, when a distinguished company, including Lord Provost Chisholm, Lord Overtoun, Sir Charles Cameron, M.P., Sir Wm. Arrol, M.P., Mr. David Cooper (manager, Glasgow and South-Western Railway), Mr. John Mathieson (chief commissioner of Victorian Railways), Bailie MacKenzie (chairman of Edinburgh Electric Lighting Committee), Prof. Andrew Gray, Prof. Archibald Barr, Dr. J. T. Bottomley, Mr. Wm. Beardmore (of Parkhead Rolling Mills), and 130 other gentlemen, attended the opening function. The party drove from the municipal buildings to Port Dundas station, where they were received by Bailie Maclay, who in a short speech welcomed the party in the name of the Electricity Committee. Mr. Porter, the building contractor, then presented the Lord Provost with a gold key, and his Lordship, having unlocked the door, declared the works open, and in a short speech congratulated the Electricity Committee on the successful outcome of their exertions.

After having inspected the engine and boiler rooms, the party re-entered the carriages and drove to the south side station at St. Andrew's Cross, where Bailie Maclay performed the opening ceremony with a gold key, presented by Mr. Green, the contractor. After a short speech describing the salient features of the station, Mr. Callender presented Bailie Willock, sub-convener of the Electricity Committee, with several pieces of silver plate as a souvenir of the occasion.

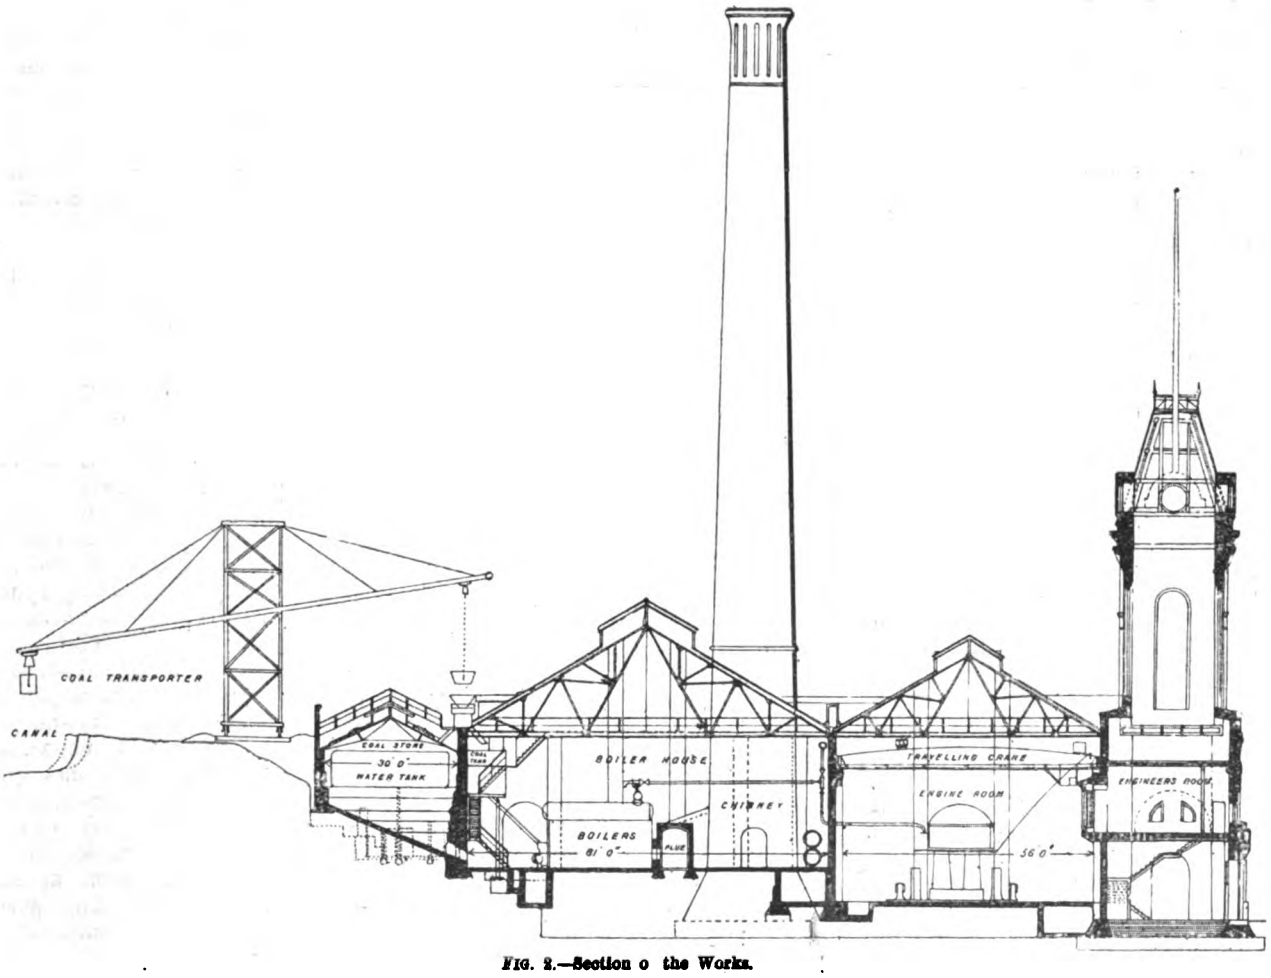

FIG. 2.—Section o the Works.

Digitized by Google

The party then returned to the City Chambers, where a banquet was given in the afternoon, the company numbering about 120. "The Queen" was given by the Lord Provost and duly pledged, after which Bailie Robert Anderson proposed "The Houses of Parliament," to which Lord Overtoun and Sir Charles Cameron replied. Numerous speeches and toasts followed. In the course of one Bailie Maclay, replying for the Electricity Committee, gave the chief engineer and his assistants credit for the indefatigable way they had worked to secure the successful issue of the huge undertaking in supplying the electrical needs of the second city of the Empire. Although an Englishman, Mr. Chamen had taken kindly to Glasgow, and he believed that in technical knowledge, zeal, and enthusiasm Mr. Chamen was not excelled by any other official in the Corporation service, a statement which was received with applause.

The Port Dundas Works.

Through the courtesy of Mr. Chamen and Mr. W. W. Lackie, his chief assistant, we had the pleasure of inspecting the station a short time after the opening ceremony. The works, which are on the north side of the city, are parallel with the Forth and Clyde Canal, which serves as a means of transporting coal to the station, passing as it does through a large portion of the Scotch coal district. The front elevation of the buildings is shown in Fig. 1. Their ultimate length will be 560ft., but at present only the middle portion is constructed. It has a length of 220ft., and at the front is located the engineers' and other offices, surmounted by a tower. Of the three chimney stacks shown only one is built—viz., the middle one, which has a height of 200ft. and a diameter of 11ft. The other two (one of which will shortly be commenced) will have a height of 250ft. and a diameter of 13ft.

Coal is brought to the station in barges, and the Temperley transporter shown in Fig. 2 and 3 lifts the coal in 15cwt. loads and transports it to the bunker. Before being discharged into this it is weighed in a weighing machine made by Messrs. H. Pooley and Co. The transporter may tip the coal either into the bunker or into tanks, which latter are directly connected to the hopper of the mechanical stoker by means of chutes. The transporter will empty a 60-ton barge in about 1½ hours. It is driven by a British Thomson-Houston standard traction motor, and as it has to work intermittently, and also reverse, it is controlled by a British Thomson-Houston controller with magnetic blow-out. The bunker, which is located on the canal bank over a large water-tank, has storage capacity for some 4,000 tons of coal. The coal-tanks, from which the coal falls by gravity to the mechanical stokers, each have a capacity of about 30 tons, and may be filled either from the barges at the wharf or from the bunker by means of the transporter. Should, however, it be considered necessary to work without the transporter, coal may be admitted directly on to the firing floor from the storage bunker; it would thus be possible to supply the boilers for 400 hours without transporting another ounce of coal, provided, of course, the bunker was full to start with. At the time of our visit the bunker was filled, and was being kept as a reserve against contingencies. A ground plan of the works as ultimately to be built is shown in Fig. 4.

Boilers.—The boilers, of which there are 10 installed, are by Messrs. Babcock and Wilcox, and are so well known that detailed description is superfluous. They are fitted with chain grate stokers and superheaters. The heating surface of each boiler is 4,020 square feet, and the working pressure 200lb. per square inch. Steel is used throughout, except the tubes, which are of wrought iron, lap welded. All the boiler fittings are Hopkinson's. Coal is brought down the chutes from the tanks already mentioned to the hopper. The chutes may be seen on the distant boilers in Fig. 5, while the coal-tanks are on the beams seen at the top right side of the photograph. From the hopper the coal falls on to the endless chain grate, which carries it forward into the furnace, the thickness of the fire being regulated by the height of the fire-door. Smokeless combustion is ensured by the slow feed, and the fact that the gases evolved from the fresh fuel has sufficient time to complete combustion before coming into contact with the relatively cold boiler tubes. The fuel is gradually consumed as the grate travels, and on reaching the end of the grate it falls over the dumping plate at the back into the clinker pit. This pit is opened periodically by means of gearing, and the ashes dumped into bogies which run along the ash tunnel. This tunnel traverses the entire length of the boiler-house. The ashes are thus removed without being brought near the firing floor. The bogies are hauled to one end of the tunnel, where at the tipping platform their contents are emptied into carts. The stokers are driven by two British Thomson-Houston enclosed motors of 10 h.p. each, so arranged that they may drive the stokers in one or two groups. The long row of boilers (there will ultimately be about 30) is divided into two long batteries by the pump-room, which at present contains two large feed pumps by Messrs. G. and J. Weir, one double and one single, with another double pump in course of erection. In addition there is a three-throw pump, supplied by Messrs. Wimshurst, Hollick, and Co., and fitted with their friction gear, which was described in our columns a few weeks ago. The city water supply is used in the boilers. No treatment is necessary, as it is an ideal water for water-tube boilers. In order to guard against total failure of the supply there are two water connections to the city mains, in two different streets, these mains entering the station from opposite ends of the building. The engines being condensing, only a small quantity of make-up water is necessary.

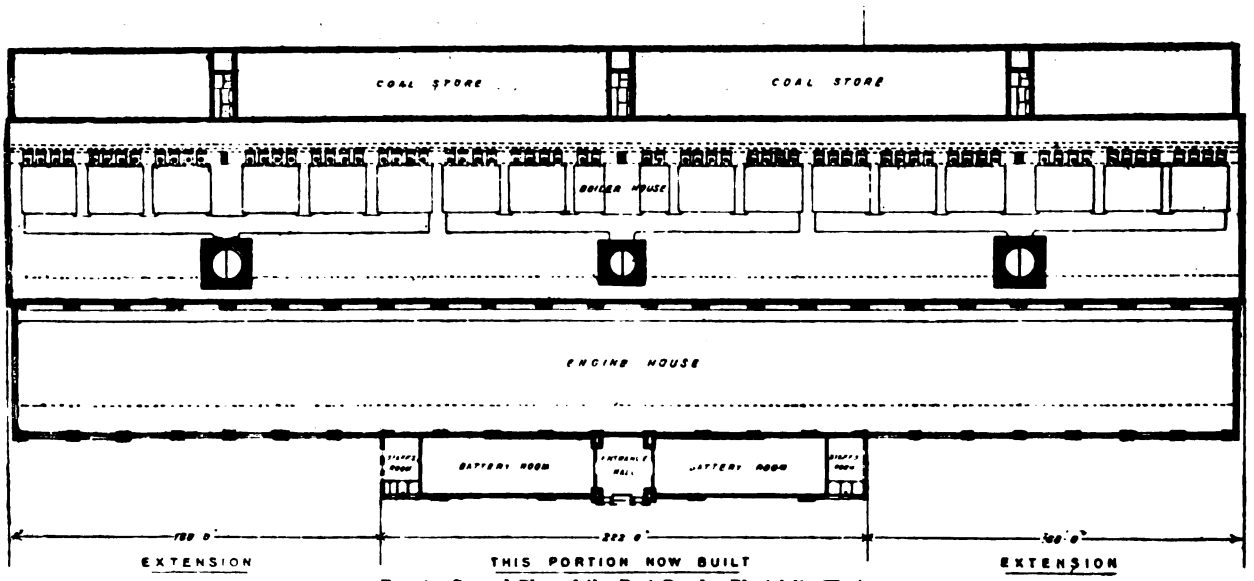

FIG. 4.—Ground Plan of the Port Dundas Electricity Works.

Steam-Piping.—From the boiler a 7in. lap-welded steel main passes across the boiler-room to a short vertical pipe on the wall, which may be divided by the valves as shown in Fig. 2. This vertical pipe connects with the 15in. horizontal steam-main, seen near the spring of the roof (this

Digitized by Google

main runs the whole length of the boiler-house), or it passes down and through the wall to the engine-room. From the arrangement of the valves it will be seen that it is possible to run any engine from the boilers, and to isolate any one of the boilers should that be necessary, all the necessary security being obtained without the use of a steam ring. It is worthy of note also that the steam-pipes are not duplicated. To provide for expansion, U bends are introduced into the middle of the boiler mains as they cross the boiler-house, while the bends in the 15in. steam-main to carry it round the chimney stack provide all the necessary expansion for its length of 200ft. All the pipes are of steel, lap-welded, and made by Messrs. A. and J. Stewart and Menzies. Below the steam-main and close to the floor are two large cast-iron water-mains. These can be seen between the chimney stack and the wall in Fig. 2. These mains are for the purpose of supplying circulating water to the surface condensers. The water is obtained from the canal, and circulated by means of centrifugal pumps. Each engine has a separate condenser, and the water is admitted to it by sluice valves operated from the floor of the boiler-room, one main being for the supply and another for the discharge.

THE SOUTHERN RAILWAYS.

Readers of the *Times* during the past few days who happened to be compelled to travel upon the southern railway lines will agree with the criticisms against the management, which conduces to waste of time and loss of comfort. It is proverbial that the lines catering for the south-eastern counties are the worst of any radiating from the Metropolis. Perhaps their condition is the result of circumstances beyond the control of the management, and unknown or unappreciated by the outsider. The starting of the twopenny tube has opened the eyes of the 'bus companies to the possibility of competition playing havoc with their daily receipts. Hitherto the competition of underground railways has had little or no effect upon the receipts of 'bus lines. Indeed, it is easy to understand that the new line may only have a temporary effect, and that the mere increase in comfort and convenience will lead to a corresponding increase in the number of travellers. If it does, in the course of time both tube and 'bus will be satisfactorily filled with passenger traffic. On the other hand, if the increase of traffic is not proportionate, then, because of its greater utility, the tube will receive the greater patronage and prosperity to the detriment of the 'bus. Long ago we pointed out that properly-constructed and well-managed tramways catering for suburban traffic against railways would probably take the greater portion of such traffic. If this view is even approximately correct, the wonder is that the railways have not themselves developed this class of traffic. Looked upon as a modified railway, the tramway is a step in upward development so far as suburban traffic is concerned. Compared, however, with the amount of traffic to be dealt with, the conclusion is inevitable that neither railway, nor tramway, nor any increased mileage of them can solve the difficulty. Our only hope is in the rapid extension of motor carriages. Within a radius of ten miles or so motor carriages will render their owners independent of either rail or tramways, their use will save time and money, and increase comfort to the individual, at the same time assisting to clear the streets and render them less insalubrious. Municipal authorities will not learn the lesson that stands clearly before their eyes; they persist in pigheaded wrongdoing. It took years to prove to them that electric lighting was possible, and now it will take years to prove that generating electrical energy upon a very small scale is not so economical as generating on a larger scale. The trail of scent left behind by the oil motor is not conducive to its adoption, but this can and will be mitigated. Already in the large towns upon the Continent motor carriages are plying for hire in competition with cabs, and, so far as can be seen, with satisfactory results. In London the attempt has been made to introduce cabs electrically driven, and failed. No one outside the company ever thought the vehicles introduced could succeed, and not till someone attempts who really understands the problem, and works in conjunction with the supply companies, will it be possible to obtain success. If people will persist in

Digitized by Google

attempting to supply what is not wanted, and supply, too, under the worst possible conditions, why they must fail. To return to the subject of railway reform upon the southern lines, or, indeed, any reform connected with commercial matters. The people who write to the papers about what ought or what ought not to be, too often forget how commercial enterprises have grown up. They have commenced by providing for the wants of the day and extending as requirements demanded. If, however, civilisation progresses too fast, or if the enterprises were initiated under conditions which prevent proportional extensions, the time comes and must come when they cease to provide the accommodation required, and then comes adverse criticism. Probably the southern lines are incapable of the necessary expansion so long as steam is the only motive power employed to adequately meet the requirements of to-day. The troubles, however, may be largely mitigated. Just as the introduction of motor traffic on common roads will assist to increase the capacity of these roads, so the extensive adoption of electricity on existing railways for the suburban passenger traffic would increase their capacity and decrease many of the troubles which are referred to by irate passengers. The trains would be lighter, would save time in starting, stopping, and running, and so enable the companies to economise time during the busiest hours of the day, and run more closely to the time-tables. So far as we can see, the difficulties to adapt existing railway lines for both steam and electricity are not very great, nor would the expense be a stumbling-block. Years hence, when America or the Continent have shown the possibility of a duplicate service, till electricity reigns alone, no doubt we shall in this procrastinating land remain content, and then to follow the leader, though, if report be confirmed, we may for once be leaders instead of followers. It is said that the Great Eastern Railway, pursuing that energetic course which has characterised it of late years, is preparing a scheme to be submitted to Parliament next session for the construction of an electric railway underneath the present track as far as Romford. We sincerely trust this report will be found to be correct, and congratulate the Great Eastern Railway upon its foresight and energy.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTROMAGNETIC INDUCTION.

SIR,—In your issue of the 14th inst. Mr. Dunton accuses me of having unjustly criticised his letter of the 25th ult. This is perhaps only natural, and I need scarcely say that I too felt perhaps an equal injustice after reading his letter of the 8th. Unfortunately for himself, the "gross misrepresentation" on which he apparently bases his accusation in no way affect the main points at issue. I pointed out that (1) the statement which he condemned as slipshod was in reality not slipshod, but a perfectly correct one; (2) that the example described by him for the purpose of proving his contention by *reductio ad absurdum* was not a legitimate one; and (3) that in this very example above mentioned an E.M.F. is induced on the vertical sides of the rectangle, in spite of his statement to the contrary. Should any doubt arise in Mr. Dunton's mind as to the existence of this E.M.F., an electrometer would be useful in clearing up the matter.

In his letter of the 8th inst., your correspondent, in referring to myself, says: "He then goes on to show that the statement to which I object does not imply that there will be a current under such conditions." This is a gross mis-statement of fact. What I actually *did* do was to point out that the statement to which he objected did not imply "that the wire connecting the ends of the conductor referred to should have an equal and opposite E.M.F. impressed on it." So much, therefore, for the "gross misrepresentation."

Mr. Dunton takes exception to a certain sentence in my letter on the ground that the second proposition "contained in it does not follow as a logical consequence of the first." Nor was it intended that it should. While admitting that in this respect the sentence lends itself somewhat to misconstruction, I would point out that the statement of two propositions does not necessarily imply that the one is a deduction of the other.

In spite of Mr. Dunton's views to the contrary, I still hold that the "lines" are graphical representations of the *direction* of the field. The *strength* of the field at any point is represented *not* by the lines, but by the *number* of those lines passing through unit area at that point.

In conclusion, I would say that, while in no way doubting the excellent authority upon which Mr. Dunton has based his contradiction, the authority in question has been misapplied.—Yours, etc., F. JOHNSTON.

Beechcroft, Holywood, co. Down, Sept. 17, 1900.

OBITUARY.

It is with great regret we have to record the death, on Wednesday morning, the 12th inst., of Mr. John Robert Jefferies, of the eminent firm of agricultural engineers, Messrs. Ransomes, Sims, and Jefferies, Limited, of Ipswich, in the prime of his life, being only in his sixtieth year.

Mr. Jefferies (whose portrait we have pleasure in producing) had been a strong vigorous man, as well in body as in mind, but had been somewhat ailing for a short time and became suddenly worse, and on the Tuesday, the day preceding his death, had an operation performed on him by his son in-law (Dr. Ward) and Dr. Herbert Brown, both of Ipswich. The cause of death was appendicitis. Mr. Jefferies was a native of Barford, in Bedfordshire. He

Digitized by Google

went to Ipswich in the year 1856, as a premium apprentice to the Orwell Works, and so attentive and assiduous was he to his duties that he was taken in as a partner by the then firm of Ransomes, Sims, and Head. When the great firm was converted into a private limited company in the year 1884 he became one of the managing directors. At first his prominent position was in the manufactory, but gradually, as some of the partners passed away, he assumed the control of the foreign and colonial departments, whilst his then co-director, Mr. James Edward Ransome, the head of the firm, devoted his time and attention to the home department. As is well known, there is perhaps no firm in the United Kingdom more eminently known than that of Ransomes, Sims, and Jefferies, Limited, and no agricultural engineer throughout her Majesty's Colonies was better known nor more highly respected and appreciated as well for his practical knowledge of business as for his urbanity and courteous manners than the late deceased gentleman. In addition to being a favourite with their many hundreds—aye, even thousands almost of employés, he was much appreciated by the members of the leading engineering firms throughout the country, and no better proof of this could be given than the fact that at his funeral, which took place on Saturday, there were representatives of most of the leading firms of agricultural engineers of the United Kingdom, amongst them being Sir Frederick Howard (of J. and F. Howard, of Bedford), Mr. Thomas Aveling (of Aveling and Porter, of Rochester), Mr. C. Burrell (of Charles Burrell and Sons, of Thetford), and many others. The funeral was a very largely attended one, there being some 50 carriages, and the streets through which it wended its way from his residence, St. Helen's Lodge, to the churchyard were densely thronged. The Orwell Works were closed for the day. The deceased gentleman will be much missed in Ipswich, for, in addition to being beloved by the numerous employés and the leading citizens of his adopted town, he was a prominent member of St. Helen's Church, and for many years a churchwarden. Mr. Jefferies leaves a widow, who is a daughter of the late Mr. Allan Ransome, the former head of the firm, three daughters, and one son, who at the present time occupies a prominent position in the business. *Requiescat in pace.*

ELECTRIC SUPPLY MAINS.

We have received from the Cablemakers' Association a model form of the general terms for a specification for the supply of electric cables and mains, which 11 of the largest firms of cablemakers in this country have adopted. The clauses in question are to take effect from Oct. 1 of this year, and the firms in question ask consulting engineers to include them in their specifications without modification, if possible. We do not know if the manufacturers in question asked any prominent consulting engineers to confer with them when drawing up these clauses, but they are so obviously in favour of the manufacturers that they can hardly be accepted always without question. Thus in clause No. 2, which deals with the guarantee, the manufacturers bind themselves not to guarantee their wares for more than 12 months without an annual charge is made for the cost of making good any defects which may arise. This is, of course, quite a trade matter, as certain of the cable manufacturers have elected to give a five years' guarantee of their cables in order to obtain a large share of work. The third paragraph of the guarantee section, however, reads as follows: "Should the contractor be required under the guarantee to locate and repair any defect which may occur in the cables, a charge for such work to be made by the contractors in all cases where there is no proof that the defect was caused by bad material or workmanship." This is absolutely absurd from the engineer's point of view, or, of course, we should say from the point of view of the local authority or electric lighting company which employs the engineer. In the case of cables with a large sectional area and current capacity, the effect of a fault is, as a rule, so destructive that the arc formed quite destroys the evidence of the original cause of the fault. Hence it would be quite impossible for the engineer to prove in a great many cases that the fault was caused by bad material or workmanship, rather than to defects in laying the cable, etc. The onus of the proof should, we think, lie with the manufacturer.

Clause 6, dealing with the suspension of the works, is fair, in that it makes the purchaser of the cable responsible for the reasonable expenses incurred due to the suspension of the works by the engineer, unless this suspension is due to any fault on the part of the cable contractor. It is not reasonable, as is too often done, to keep the workmen of one contractor on the spot when there is no chance of their completing the work due to either unforeseen troubles connected with the building site or to any other cause over which the cable contractor has no control. The Clause 8, dealing with engineer's certificates, is worthy of support throughout the whole profession, particularly when it undertakes that the purchaser should pay the contractor within one month of receiving the certificate from the engineer that the payment is due. We do not, however,

STANDARD SIZES OF CONDUCTORS FOR ELECTRIC SUPPLY MAINS.
To become operative on October 1, 1900.

Nominal size of conductors in square inches.	No. and diameter of strands.	Resistance in standard ohms per 1,000 yards.			Weight in lbs. per 1 000 yards.	
		Calculated.	Maximum allowable.	Maximum allowable for tinned wires.	Calculated.	Minimum allowable.

In concentric cables the outer conductors will have the resistance orresponding to the areas as given above.

Digitized by Google

think that the contractors are justified in trying to force the engineer to issue the certificate within 14 days of the presentation of the account. It frequently happens that 14 days is not sufficient to properly check and investigate the account and the points of difference which exist between it and what the engineer admits that the contractor is entitled to. On the whole we think that the clauses will be useful, with the exception of the few points to which we have drawn attention, and any difficulty about these, we think, would be avoided by consultation beforehand with a few of the engineers usually having control of such work. The table of standard cables reproduced herewith is issued with the clauses above mentioned.

FIRE AT THE MANCHESTER POST OFFICE.

About half-past one o'clock on Wednesday afternoon a fire broke out in the telegraph instrument room of the Manchester General Post Office, and before it could be got under had caused so much damage as to completely cut off all telegraphic and telephonic means of communication with the rest of the country. The fire was first discovered in a test-box, behind which were a number of wires. Suddenly flames were seen coming from the box, and immediately the whole apparatus was enveloped in flames. The woodwork in the room being very dry, the fire spread with alarming rapidity, the efforts of the clerks in the room to subdue it making not the least impression. Communication was thereupon made to the Manchester fire brigade, and within a very short space of time several contingents were on the scene. On their arrival, under Chief Officer Mr. Parker, it was found that the whole of the instrument-room on the top floor of the building on the Brown-street side was in flames, and at first sight it appeared absolutely hopeless to prevent the entire destruction of the building. Jets, however, were promptly got to work, and an immense volume of water was at once poured on the burning mass. In the meantime the flames continued to obtain the mastery, and in a very short time the portion of the room in which the outbreak occurred was completely dismantled. The telegraph instruments were, of course, very soon destroyed, and it was not many minutes before the roof fell in in several places. The telegraph wires over the building were dislodged from their supports, and this, coupled with the damage occasioned to the instruments, had the result of completely suspending telegraphic communication between Manchester and elsewhere.

Fortunately, although there were between 200 and 300 operators at work in the instrument-room when the outbreak was first discovered, there was not the slightest sign of panic manifested. Each one left his post and retired to another part of the building in admirable order. The appliances provided at the post office for dealing with emergencies of this character were inadequate to meet the demands made upon them, and had it not been for the timely arrival of the city brigade there can be no question that the whole building would have been doomed. As it was, the supply of water obtained from the main and poured upon the fire, under the direction of Mr. Parker, was sufficiently ample to bring the conflagration into subjection within a comparatively short period, and by two o'clock all immediate danger of any further spread was at an end. The postal authorities at once set about to devise means to remedy the inconvenience to which the public must necessarily be subjected in consequence of the dislocation of telegraphic communication, but for some hours everything was in a state of chaos, and it is impossible to say how soon things may be got to work again. In addition to the supply of water direct from the mains, it was found necessary to get one of the steam-engines to work, and this was the means of putting the finishing touch upon the efforts of the brigade to suppress the outbreak.

The fire, it appears, was caused by the bursting of a spirit lamp which was being used by some employés of the engineering department, who were repairing the wire coils near the test-box. This is the point where all the wires entering the building converge, and is, accordingly, one of the most important spots in the building. The whole of the work of the office, both telegraphic and postal, was for the time being reduced to a state of confusion when the employés re-entered the lower parts of the building. Announcements were, therefore, made, and within a few minutes, that no messages could be accepted for dispatch during the remainder of the day. The telephone department was also closed. Under ordinary circumstances, the inconvenience to the public would have been immense, but it will be all the greater just now in consequence of the pending Election, the arrangements in connection with which had been almost completed by the district superintendent. The department of the engineer-in-chief in London was communicated with at once, and it is hoped that the assistance to be obtained there, as well as from the engineering departments of some of the other principal offices in the country, will enable the Manchester authorities to remedy the effects of the disaster in the course of a week or so.

The building has sustained considerable damage, the whole of the roof of the northern wing having been burned away, and it will be many weeks before it can be replaced. It is hardly possible to exaggerate the enormous inconvenience and loss which must accrue to the business community of Manchester owing to the fire. Merchants and manufacturers are, for the time being, entirely cut off from their customers and from communication with their own mills, which are frequently situated many miles away.

For the above account of the fire we are indebted to the *Standard*. We also learn that at 4.45 p.m. connection between London and the Manchester Stock Exchange was established. The railway company put their wires at the disposal of the authorities. This is the second fire within a comparatively short period caused by a spirit lamp exploding and igniting the insulation on telegraph conductors. The first occurred in a street box in London, and resulted in great inconvenience. The monetary loss, however, to the Post Office authorities was comparatively small compared to that at Manchester. It shows, however, that the engineer's department should look into the design of their spirit lamps, as they at present seem to be far from safe.

THE EVOLUTION OF SWITCH GEARS FOR HIGH-PRESSURE ALTERNATING CURRENTS.

BY W. E. WARRILOW.

(Continued from page 374.)

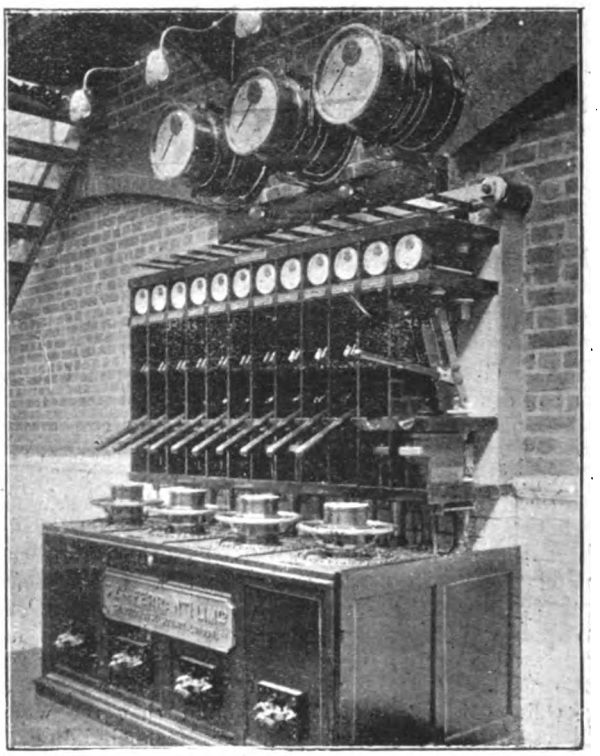
FERRANTI.

The switchboard introduced by Mr. Ferranti is a distinct departure from every other type, and it possesses such marked advantages in its arrangement that it is being almost generally adopted and replacing other gears. The principal features of the board have remained much the same as in the early types, the chief developments having taken place on lines of flexibility, or construction with an aim to standardisation. The gear is composed of four main slates grouted horizontally into the wall for support, and grooved at certain centres (according to power to be controlled—6in. for panels up to 600 kw., 9in. any higher power) for the reception of vertical slates which divide the main slabs into a number of cells. These slates are black enamelled, but the wall behind the compartments is faced with slates which are white enamelled. Each cell is fitted with cable receiver, fuse, switch, ammeter, and 'bus bar fitting, all these being so arranged that they complete the circuit without the aid of rubber cables or any connection behind the wall. Mr. Ferranti was the first engineer to advocate the connection of one conductor of a high-pressure system to earth, and the taking of every precaution to thoroughly insulate the other conductor. He put his suggestion into practice in the construction of his switchboard by connecting the outer conductor to an uninsulated bar beneath the gear, and carrying out all switching, etc., arrangements on the inner, which was most carefully insulated, the 'bus bar being located at the top of the gear.

The first complete board in this country on this principle was erected at Portsmouth in 1894, and the photographs

Digitized by Google

(Figs. 43 and 43A) show two views of the gear. At the top of the board, fixed on the wall, are the voltmeters, each mounted on its own converter, and underneath these are the synchronising lamps. On the high-tension board will



FIGS. 43 AND 43A.—Main Switchboard, Portsmouth Electricity Works.

be seen the inner 'bus bar (carried on shanks sulphured into porcelain insulators cemented in the wall), 'bus bar fittings coupled with spring copper link, ammeter, spring break switch, single contact fuse, and cable receiver. Below this gear is the regulating table carrying rheostat, ammeter and field switch. The resistance wires are placed directly

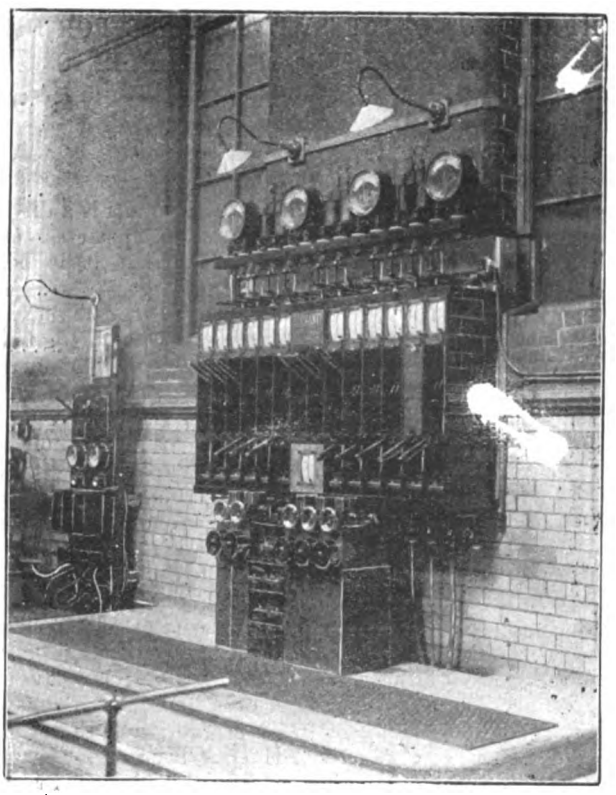


FIG. 44.—Switchboard at Hanley.

underneath the regulating switch and connected to the stops by cables. The ammeter being mounted in the centre of the handwheel of the rheostat, the exciting current could be easily seen during the operation of regulating the volts. The outer of the high-pressure concentric cable is connected to the shell of the receiver and thence to the outer 'bus bar (earthed) by means of a link, the inner of the cable being connected to the panel above. The fuse panel contains contacts into which an oil-break fuse of Messrs. Ferranti's well-known type is inserted. A short-circuiting plug is provided for the removal of the fuse. The switch is of the spring-break class, and is fitted with

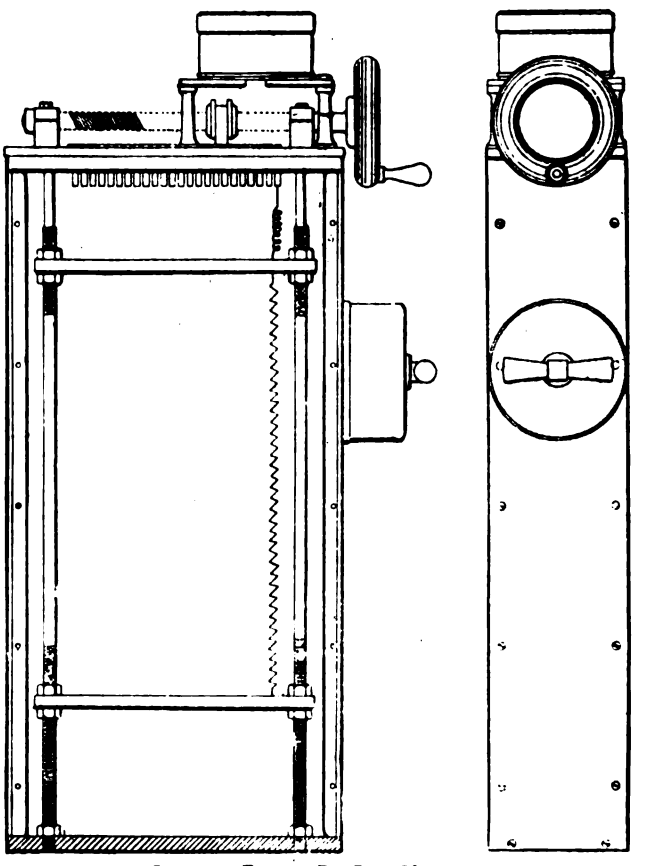

FIG. 44A.—Ferranti Box-Type Rheostat.

half-cock synchronising contact. This may be seen clearly in the side view photograph of the board. The ammeter is a circular one, and is connected to the main fittings by copper rods. Parallel running of the alternators was almost rendered necessary by the inner 'bus bar links, but

Digitized by Google

a certain combination of machines and circuits could be effected if desired.

Fig. 44 illustrates a stage in the development of the board. This was erected at Hanley, and when compared with the Portsmouth gear the differences will be at once evident. High-tension voltmeters and neat synchronisers are mounted on a slate above the main board, and each is arranged that its supports act as terminals, the high pressures being fixed into insulators at the front of the slate, and the earth terminals screwed into a common bar connected to the outer 'bus bar at the bottom of the board. Fine fuses drawn through glass tubes fitted to a suitable handle connect each instrument to its particular bar, and the withdrawal of the fuse makes the examination or removal of either voltmeter or synchroniser a safe operation. The ammeters, arranged to be easily removable, are provided with a bold open scale and large needle. In the fuse panel, duplicate contacts are fitted so that a spare fuse may be inserted or a faulty one removed without interruption of supply. The rheostats are constructed to occupy a similar width as the high-pressure panel, so that each may stand under its own line of apparatus. Fig. 44A will explain the construction of this type, where it will be seen that ammeter and field switch are included in the arrangement. This form of resistance will dissipate up to 300 watts, and the lower slate may be adjusted by nuts to take up any slack in the wires. This switchboard is fitted with two inner bars, which can be connected together by an interconnector switch, so that alternators running in parallel may be separated to supply a number of circuits on either side of the board.

(To be continued.)

MUNICIPAL TRADING.

BY ARTHUR PRIESTMAN.

The following is an abstract of a long paper by Mr. A. Priestman, read before Section F of the British Association at Bradford on Monday, Sept. 11. The author commenced by the assertion that "the subject of municipal trading is ripe for discussion. Anyone acquainted with the municipal work on town councils must be aware of the difficulties continually arising as to how far municipal activity is to be allowed to enter a domain which hitherto has been regarded as the exclusive province of the private trader. The London Chamber of Commerce has recently issued a circular to the provincial chambers asking for information as to what local evidence can be obtained on these points, amongst others: (*a*) whether the rates ought to be put into competition with private capital; (*b*) whether the local authority ought to become traders, by providing services which are not of general use to the whole community; (*c*) what the effect has been on local wage lists of the municipality setting a high standard of wages for the Corporation employés. The answers to these questions are desired in order that a case may be prepared in the interests of private traders. As you are doubtless aware, a Royal Commission has been sitting, which is to make a report to the House of Commons in due course, and upon which future legislation will probably be based. Few people will find cause to quarrel with municipal trading in water, electricity, and gas. What has come to be recognised by most as the rightful domain of municipal enterprise is so well established that we need not stop to consider the arguments for and against its continuance. The cities and towns have risen to their responsibility, and have spent vast sums of money in obtaining the consent of Parliament to their loans after semi-judicial public enquiry. The safeguards against rash or extravagant expenditure by these means appear to be most amply sufficient, and, if anything, err on the side of over-caution. The men on the city councils who are responsible for the civic enterprises in gas, water, and tramlines are in most cases the very men who have taken the most part in the private enterprises of the town, and have themselves become wealthy with the increasing local prosperity, and it is hardly likely that these men (provided they are returned as before) will engage in too rash or dangerous corporate experiments."

The author proceeded to deal with the increased municipal responsibility entailed by trading and on the backwardness of the United States in municipal works. As a mark of the growth of municipal enterprise in this country, Mr. Priestman instanced the amount of debt incurred by the local authorities in England and Wales, which, according to Sir Henry Fowler, was estimated in 1868 at £60,000,000. In 1875 this debt was nearly £93,000,000; in 1885, £173,000,000; and in 1898, £262,000,000. He informs us also that the National Debt in 1898 stood at £638,000,000, and that between the years 1875 and 1898, whilst the National Debt was reduced £131,000,000, the local debt during the same period increased by £170,000,000. But this sum of local indebtedness includes schools, asylums, highways, sewerage, and other necessary expenditure which cannot be classified as strictly municipal trading. Sir Henry Fowler classifies the local indebtedness of 265 municipal boroughs in England and Wales, excluding the London County Council, as follows: £137,000,000 for purposes which local authorities are bound to provide, £36,000,000 for educational and recreative purposes, £87,500,000 for trading, and the remainder for advances for private improvements to be repaid. These trading purposes may be divided into six principal classes: waterworks, gas, markets, tramways, electric lighting, and piers, quays, and harbours. Of the 265 municipal boroughs in England and Wales, but excluding the London County Council, 173 manage their own waterworks, 87 their own gasworks, 204 their own markets, 28 their own tramways, and 55 their own electric light works. But what is most remarkable is that, after paying interest on loans and sinking fund, the margin of profit generally applied to the reduction of rates is only ½ per cent.

The author then treated the subject of municipal buildings for the working classes, etc., and then came to the subject of telephones. On this head, he considered that the charges of the National Telephone Company for the use of their instruments in Bradford were high, being £10 per annum, whilst at a small town like Trondheim in Norway, with 30,000 inhabitants, the subscriber pays for a municipal telephone £3. 10s. per year, a charge which affords a surplus, after paying interest on capital, a reserve of 5 per cent. per year on the capital, and the insurance of employés against death, accident, and sickness. The Bradford Corporation surveyor had very recently estimated the complete cost of establishing a municipal telephone exchange in Bradford, based on the present number of subscribers on the books of the National Telephone Company, at £40 per subscriber, including all buildings, wires, and instruments, so that it is not unreasonable to conclude that the city could afford to supply a telephone service at no greater charge than Glasgow City Council is offering—viz., £5. 5s. per annum per instrument. Now that the newer system is to lay the telephone wires underground, the streets must be interfered with by the Telephone Company, and the municipality cannot grant powers to do this to a private company any more than they can grant powers to a private tramway company. It was never to the public convenience that two authorities should have power to interfere with the streets. Since the fire insurance companies have formed a combination and fixed upon a tariff rate which to most seems a very heavy charge, this will force the trading public to consider whether this monopoly charge must not be resisted. The conclusion of the paper was devoted to the support of municipal trading in its widest sense.

A paper on "Municipal Housing for the Overcrowded," by the Hon. Auberon Herbert, was then read, and the two papers were discussed together. For the report of the discussion we are indebted to the *Bradford Observer*:

Mr. E. Bond, M.P., who opened the discussion, said that the subject dealt with in the papers was one of great importance, and he really wished that the issue had been raised in a clearer form than had been done in the papers. What they had to consider was whether and to what extent they could enlarge the sphere of municipal enterprise, especially in the direction of taking up businesses that were ordinarily carried on by private enterprise for profit. He must say that the reader of the first paper had not clearly drawn any definition of the functions which municipalities should discharge, or which they might be called upon to define in the future. They were all agreed that a municipality should look look after the health of its population, should see that the streets

Digitized by Google

were properly paved and lighted, and should exercise a large number of multifarious functions depending to some extent on local circumstances, but not in any case for the sole purpose of making a profit. In these functions were included the supply of water, gas, and electricity, and they were all agreed that a municipality might well undertake businesses of that kind—businesses which were often carried on, no doubt, by private companies or individuals. The reasons given for that—reasons which he thought absolutely conclusive, at any rate in the case of water—were that it could be shown that by the municipality providing for the supply of water the ratepayer could obtain, without any loss, a supply as good and as abundant as he could obtain by private enterprise, and, further, that a municipality could do this work with almost perfect safety, as it was inconceivable that they could ever reach the stage when they could do without water as a prime necessity of life. Therefore, the municipality in that matter might be pretty sure that it would not become involved in financial disaster. He was rather more doubtful with regard to gas and electricity, because it was not beyond the bounds of probability that some new illuminant might be discovered that would entirely replace gas and even electricity. In such a case, a municipality might find itself in a difficult predicament, and as the members of the corporation were only human and were actuated by similar motive to other human beings, they might hesitate before giving their sanction or encouragement to introduction of anything new that was likely to endanger the capital invested by the municipality in its gas and electricity. He admitted that municipal gas undertakings had, on the whole, turned out well, though there was always the trouble of their being obliged to differentiate between their customers—of their having to decide whether they would supply business men with gas at a cheaper rate, or whether they would devote their energies to bringing the gas at the cheapest rate to the door of the poorer ratepayers. But it seemed to him that the question of profit was in most cases an all-important consideration. Mr. Priestman had pointed out that in the case of Bradford the gas enterprise had been making a large profit that had gone to the relief of the rates, but he was staggered to find that, owing to the increase in the price of coal, the profit this year would be converted into a deficiency. This showed the risks in which a municipality became involved when they embarked in these trading industries. One of the gravest questions arising out of municipal trading was the question of large numbers of ratepayers being in the employment of the municipality. A councillor might represent a district where the council's employés formed a large part of the electorate, and the interests of these employés might at any time be in conflict with the interests of the ratepayers at large. The result would be that there would be a strong inducement to a councillor to favour the interests of the employés at the expense of the ratepayers. In that way the door was opened to municipal corruption. The whole idea seemed to be that persons who otherwise had no special knowledge of the kind of business entered upon were perfectly capable of undertaking the control of any business simply because they were called a municipal corporation. Mr. Priestman seemed to see no limit to the kinds of trading into which the municipality ought to enter; anything that seemed to offer the probability of a profit should be grasped at. He expressed the opinion that every reason that rendered the municipalisation of the water supply desirable applied equally to the milk supply, but he (the speaker) did not agree with this at all. Even if it should be admitted that milk were a prime necessity—though it was not so to the same extent as water—yet the organisation of a milk supply was a far more complicated and difficult thing than that of a water supply, and involved an element of uncertainty that should not be undertaken by a municipality. Another objection to the further extension of municipal trading was the immense amount of work which was thrown upon the members of the corporation. In the case of the London County Council, of which he was a member, it was already found that the mass of work was so great that only a very small part of it could be properly understood by any one member. The result was that they had to rely more and more upon the paid servants of the Council, and though they might be on the whole well served—as he believed they were—by their paid staff, there was always the danger of the work getting into the hands of men who were either incompetent or who would yield to the temptation to corrupt influences. As illustrating the way in which a municipality failed to carry out its trading schemes successfully, he instanced the attempt of the London County Council to provide for the housing of the poorer classes—the people that were dispossessed by the destruction of insanitary rookeries and slums. The London County Council had found it impossible to provide the kind of dwellings required by this class of the people except at a great cost to the ratepayers, which it did not feel justified in incurring. For these reasons he thought they should be desperately on their guard against extending the system of municipal trading. So far from sharing Mr. Priestman's view that the health, wealth, and well-being of the community would be advanced by the extension of municipal enterprise, he was of a directly opposite opinion. He believed the municipalities would find themselves in a financial muddle if they went much further on these trading lines. There was no reason to believe that articles of general consumption could be supplied cheaper, better, or more suitable by the municipalities than they could be supplied by private enterprise. If an article supplied by private traders was unsuitable or unsatisfactory, the purchaser could go elsewhere, but if the municipality possessed a monopoly there was no inducement to supply the best or most suitable article, while the ratepayer would be in the position that he must take the article supplied or go without.

Prof. Silvanus Thompson said that in taking part in the discussion he would confine himself to one small corner of the subject raised, and that was as to the bearing of the electricity question on municipal trading. He would, however, just say that Mr. Priestman's suggestion was that no limit ought to be put upon the growth of municipal trading or to the development of collective enterprises. But he might be permitted to point out that there must be some limit, and he believed that even as regarded tramways and lighting the extent of municipal effort must be limited. With respect to electricity, he was glad to learn that Bradford was almost the first in the field in electrical lighting. They were excellently advised also when they proposed to supply electrical power cheaply to their customers. Again, he thought they were equally well advised when they determined to take over the tramways and to work them by electricity. But he would observe that when they did so they were bound to consider not only the needs of their own town, but the needs also of the districts outside that desired improved communications. They should bear in mind that their tramway system would be of far greater advantage if it were part of a network of tramways covering a large district, as had been done in many instances in America, where there were electric trams extending continuously for 20 or 30 miles. In Bradford they found themselves in possession of horse tramways with a narrow gauge. Why, when they had to relay these lines, did they not alter the gauge so as to make it the same as in the rest of Yorkshire? They would have to pay the penalty for that municipal mismanagement on that point in the future. In five, ten, or fifteen years they would have to take up their lines and relay them of the same gauge as the other Yorkshire lines. He understood that the reason the gauge was not altered was that the committee sought to save the cost of a few old tramcars which could be run until the electric ones were ready. There was now coming before them the far larger question of the supply of electrical power to mills and factories, to large consumers as well as small consumers. To do this they would have to have central stations that would supply electricity on a large scale, for 30,000 h.p., 40,000 h.p., or 50,000 h.p. was likely to be required. If they had a large central station they would be able to send out electricity at a far cheaper rate than if they confined their attention to the same area as for gas or electric lighting. It would be just as if a London vestry proposed to supply gas or water instead of allowing the County Council to provide it for the whole area. In the case of the supply of electricity on a large scale they must have, not the municipality as an area, but the county or a large section of the county. If the municipality did not provide for this, so much the worse for the municipality in the long run. As an illustration of this he referred to the fate of the Lancashire Powers Bill in the last session. That scheme, he said, was well thought out, and proposed the establishment of large centres whence they could carry electric cables through large districts. But certain bodies objected to the powers sought for, such as the power to interfere with the streets and roads, and other authorities objected that they themselves already possessed the powers to supply electricity. But the scheme proposed would not have interfered with any of the rights of those authorities; the proposal was to supply electricity in bulk to the authorities and to others who already possessed the power to distribute it. To get to these people it was necessary to pass through other areas that did not require the supply, but that ought not to have led these intermediate authorities to place themselves in antagonism to the scheme which proposed to supply other persons beyond who did need it. In the case of Bradford were there not urban districts beyond its borders who had as much right to a cheap supply of electricity as had Bradford itself? Why, then, should not Bradford be prepared to co operate with other places in establishing these great central stations? Another point was that the circumstances of different towns and industries varied. In Bradford they had one chief industry, and the various manufactories requiring power began and ceased work at the same time. The consequence was that the demand for electricity was restricted to only a portion of the day, and they required a large amount of costly machinery which would necessarily stand idle for the greater part of its time. But if they had areas of supply covering various industries, in which the times of working overlapped each other, they would be able to work with a comparatively smaller plant, which would run almost continuously, and the out-turn of power would be more regular and consequently cheaper. He, therefore, asked that the question of electrical power should not be regarded as a parochial or local question, but as a far larger question that involved the prosperity of the whole of Yorkshire.

Other speakers followed on the general question, and we regret that we have not space to reproduce their remarks.

Tariffs Remitted.—It is interesting to note that, in view of the electric lighting of Georgetown and New Amsterdam, in British Guiana, the tariff which has up till recently been imposed upon electrical machinery has been removed. Telegraph supplies and tramway material have also been added to the free list. The information is very pleasing, as it not only shows that great efforts are being made in British Guiana to keep up to date, but also that the Colonial authorities look with favour on these efforts.

QUESTIONS AND ANSWERS.

[N.B.—Will the gentlemen who sent in questions Nos. 304 and 305 kindly forward their names and addresses, as they cannot be traced? Their initials are "F. H." and "A. S."—ED. *E. E.*]

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

309. Explain, with sketches, all the connections of a balancer-booster on the three-wire direct-current system where the booster is used for battery charging.—F. H. P.

310. Describe a method of determining the current (with a certain temperature rise, say, 100deg F.) which can be carried by high-resistance wires, such as platinoid, rosteéne, tinned iron wire, etc., when used for resistance coils, and when their specific resistance is not known.—F. W. B.

ANSWERS.

Question No. 303.—Explain the use and working of the Kelvin earth-current recorder, with automatic short-circuiting switch. Give diagram of connections.

Best Answer to No. 303 (*awarded* 10*s.*).—A general view of a Kelvin earth-current recorder, with automatic short-circuiting switch, is given in Fig. 1. The recording ampere-meter, R Am, consists of a pair of coils, Am C, fixed in the bracket shown, and a series of small magnets attached to a pivoted aluminium frame not shown in the sketch. A light pointer with an ink pen at its end is fitted to the frame carrying the small magnets, the latter being free to move in the centres of the coils, the pen, of course, moving over a graduated paper slip on the clockwork drum. The automatic switch consists of the horseshoe magnet, H M, having a circular core iron dipping into the coil, S, the height above the coil being adjusted by the milled nut at the top. Below the poles of H M is pivoted an iron keeper, P K, which is pulled up by the magnet when the coil, S, is energised, thus lifting the small catch, T. The switch proper is shown closed in the sketch for the sake of clearness, but in its normal position it is lifted by hand vertically, until the rib, W, cast on the inside of the switch arm engages the catch, T, when it is held securely in that position.

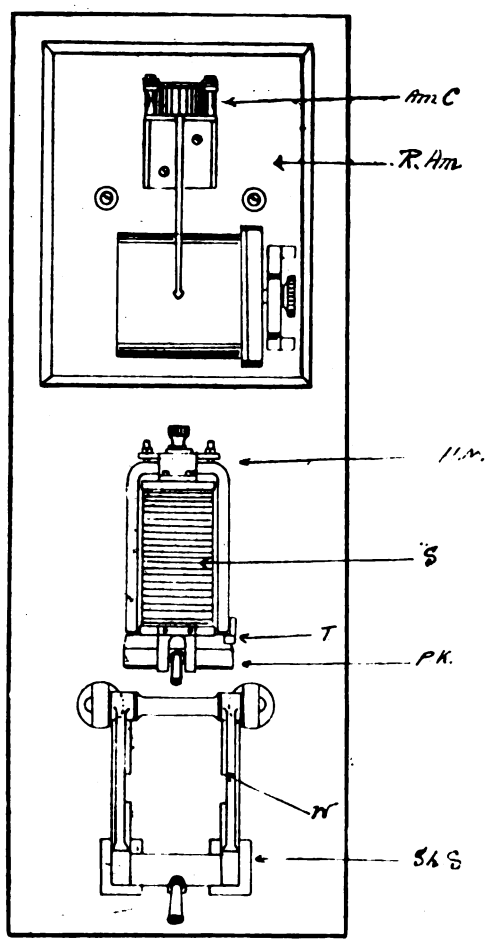

FIG. 1.

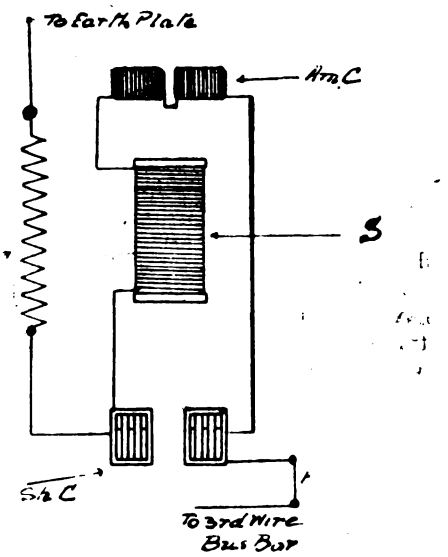

FIG. 2.

A diagram of the connections at the back of the instrument is given in Fig. 2, where Am C represents the ammeter coils, S the actuating coil, Sh C the short-circuiting switch contacts, and Sc R a special series resistance supplied with the instrument to carry about 15 to 20 amperes. The connections are represented for the earthing of the neutral wire of a three-wire system at the station end through the instrument. The action of the instrument should now be quite clear. Thus, supposing the magnet, H M, to have been so adjusted that when five amperes passes through the coil, S, it becomes sufficiently magnetised to raise the keeper, P K, until it lifts the catch, T, and so leaves the switch, Sh S, to fall of its own weight, thus bridging the contacts, Sh C (Fig. 2), the instrument then being cut out, and the resistance, Sc R, put to earth through the fuse, F.

To use the instrument to the best advantage, a three-way switch might be inserted between the fuse, F, and the source of supply, so that by moving the switch, say, to No. 1 contact, the instrument is coupled to the neutral wire, No. 2 to negative main, and No. 3 to positive, the contacts being so set out that they cannot be bridged; or, better still perhaps, a set of three plug sockets to receive the plug connected to fuse, F. By means of this method of connecting, the insulation resistance of the whole network may be taken roughly each day and notes made, so that the gradual development of a slight fault to earth may be watched; also by marking the scale for a positive or negative deflection, the faulty main may be detected. The above may be calculated from the formula $F = \frac{V}{d^1 - d^2} - g$, where F = insulation resistance of the whole network; V, the working pressure between the two mains from which deflections are taken; d^1 and d^2 deflections obtained from, say, middle wire and earth and one of the outers; g = resistance of testing ammeter and its auxiliary resistance. The expression $(d^1 - d^2)$ being the algebraical difference between the two readings, they must, that is to say, be added together if the deflections are to opposite sides of the zero. For a fuller description of the above and similar methods see Raphael's "Localisation of Faults in Mains."—A. H.

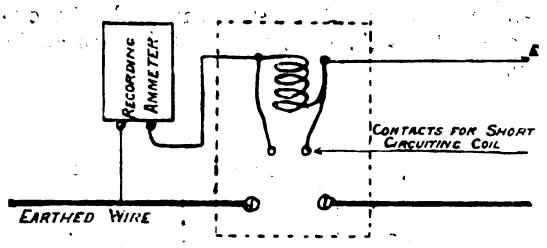
Answer to No. 303 (*awarded* 5*s*).—The Kelvin earth-current recorder is a simple recording ammeter constructed on the principle of the Thompson galvanometer with an astatic pair of needles, each being surrounded with its own coil, which are wound so as to be traversed by the current in opposite directions; these coils are built up of copper tape. For recording, the usual clock indicating arrangement being attached to the instrument, one terminal of this ammeter is put in contact with the wire to be earthed; the other terminal is connected through the electro-magnetic releasing arrangement of the short-circuiting

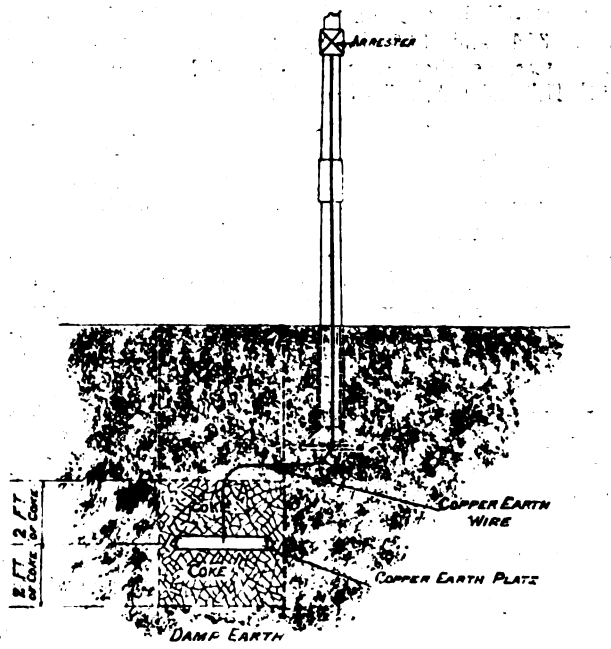


switch to earth. The short-circuiting lever, which consists of an ordinary knife-edge switch, is held out of action by a catch attached to the armature of the electromagnet, round the coil of which passes the current going to earth. The iron core of this electromagnet is so adjusted that when the maximum current allowable passes to earth the armature is attracted, thus raising the catch releasing the switch arm, which falls by its own weight into the contact-pieces, and thus complete the circuit through the switch arm without earth. Further, there is an arrangement on the arm by which the terminals of the coil of the electro-magnet, and therefore the recording ammeter, become short-circuited just before the switch makes contact with the two terminals of the wire that was previously earthed. A diagram of the connections is shown in the accompanying illustration.—J. C. B.

Question No. 304.—What are the best and most useful forms of earth-plates used for lightning arresters?

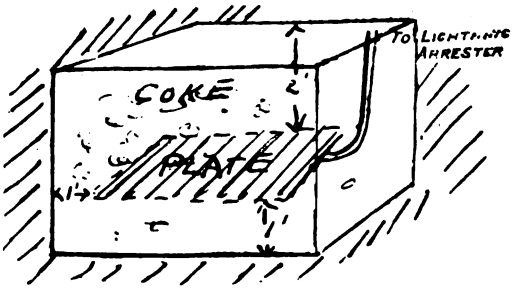
Best Answer to No. 304 (*awarded* 10*s*.).—The entire benefit to be gained by the use of lightning arresters may easily be neutralised by disregarding the importance of providing a good earth connection, so that too great stress cannot be laid upon the absolute necessity of making an efficient connection to earth. How this may be most easily and effectively accomplished will depend upon the nature of the soil at the point at which the arrester has to be earthed. The most desirable place for fixing an earth-plate is in a rich, damp soil, and although this dampness is essential for an efficient connection, the error is sometimes made of thinking that too much water cannot be present, and advantage taken of the close proximity of a pool or stream to totally submerge the plate in water. This is a great mistake, as in reality only a very poor earth contact is made, owing to the high resistance of water. We may also include clay, rock, gravel, sand, and dry earth as being unsuitable substances in which to bury our earth-plate.

The following remarks as to size and method of fixing and connecting an earth-plate may be taken as applying to average cases, although the dimensions are only approximate, and may be often deviated from to suit special requirements; for instance, it may be necessary to bank a large number of arresters together and connect them all to one plate, in which case this must naturally be increased in size. The plate should be made of 16 B.W.G. copper, and be approximately 3ft. square and be well tinned. A hole about 4ft. square should be dug in the ground until permanently damp earth is reached; the bottom of the hole should then be covered to a depth of 2ft. with small crushed coke or charcoal and the earth-plate placed on top of this, and then a further layer of 2ft. of coke, the hole being finally filled in with earth, running water being used to settle. Where it is impossible to find dampness, water should be provided by means of a galvanised iron pipe. The connection from the arrester to the plate should be as short and direct as possible, be made of copper, and well soldered all across the plate. The accompanying sketch roughly illustrates this method of fixing, which is very simple and efficient.

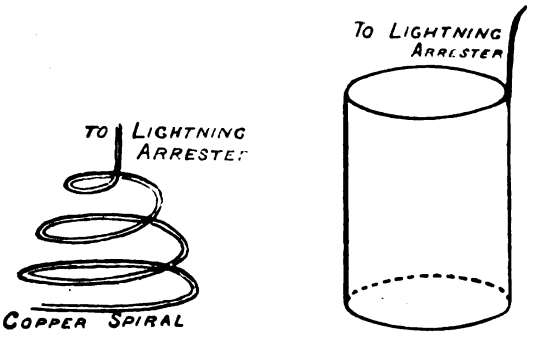


In cases of transmission of power schemes in which barbed wire is stretched from pole to pole above the transmission wires and the poles then earthed, a good connection may be made by burying a galvanised iron plate about 3ft. square at a point as near to the pole as the nature of the earth will allow, the plate and pole being connected by means of barbed wire well soldered to each.—F. A.

Answer to No. 304 (*awarded* 5*s*.).—There are several forms of earth-plates in use with lightning conductors; the most general is a flat copper plate, having an area of about four square feet. This plate is buried in coke, the coke being about 1ft. below, 1ft. round edge, and 2ft. above



the plate. The other forms of plate, which, however, are not in such general use as might be wished, consist of a copper spiral and a copper cylinder. They are buried in coke, and the object they seek to obtain is the tapping of a larger area of earth and the provision of a larger contact surface. The spiral consists of 2in. by ¼in. copper, and the



largest diameter is about 4ft., the height of the coil being also not less than 4ft. The cylinder, besides aiming at a large contact area, also aims at keeping the coke moist, and in such a state that its conductivity is increased. Either of these two forms are preferable to the ordinary flat plate.—A. G. M.

Answer to No. 304 (*awarded* 5*s.*).—A thoroughly good earth is really a geological question, and for a building of great importance a specialist on the subject should be consulted. Gas and water pipes should not be used for the purpose, as in dry weather these afford very poor earth connections. The best and most useful form of earth connections consists of a large plate of copper buried in the earth, surrounded with coke, cinders, or carbon, by which the surface of the plate is greatly increased, and a much more intimate contact with the surrounding earth is also made on account of the good conducting properties of the carbonaceous mass. The whole is afterwards saturated with water, thus increasing still further the surface and contact. Further, the copper plate becomes coated with a layer of sulphide by the chemical action, and is thus protected from any further corrosive action of the damp earth. In places where there is a watercourse, such as streams or rivers of sufficient size to be never dry in times of drought, or if lakes or large ponds be near the conductor, it is sometimes thought sufficient to place it in constant contact with the water; but there is always the liability of the metal corroding at the point of the liquid surface, and becoming eaten through, thus breaking the earth connection.—J. C. B.

LUTON ELECTRICITY WORKS.

Last week saw the laying of the foundation-stone of the new electric light works and highways depôt by Councillor Wilkinson, chairman of the Electric Light Committee. The stone bore an appropriate inscription setting forth that it was laid by Councillor Wilkinson, chairman of the Electric Light Committee. The names of the committee and the Council; Mr. A. J. L. Evans, architect; Mr. A. T. Snell, electrical engineer; and the builders were also added. The Mayor (Alderman Hucklesby), wearing his gold chain and robe of office, Mr. T. G. Ashton, M.P., Mr. G. Elliott, aldermen and councillors of the Corporation, representatives of various public bodies, and the borough officials attended. A luncheon followed, at which the usual toasts were proposed and duly honoured. We are indebted to the *Luton Times and Bedfordshire Advertiser* for the following description of the works.

The buildings have a frontage of 122ft. 6in. to St. Mary's-road, and a depth of 64ft., and are set back from the line of street 20ft. The block comprises—on the ground floor, accumulator-room, engine-room, boiler-house, pump-room, coal bunkers and workshop, engineer's office on first floor, and meter stores, etc., on the second. The front elevation to St. Mary's-road is faced with best Luton grey bricks, having panels formed with pilasters of Ibstock, red facings, and moulded bases, the cappings, reckings, and strings being formed with moulded Bath stone. The main entrance into the hall is built with red terra-cotta, having jambs and arch moulded and deeply recessed, also moulded and empanelled spandrils filled in with medallions. The same description applies also to the main entrance into the boiler-house, excepting that the words "Fiat Lux" are added in the spandril panels. Above the entrance a terra-cotta panel embraces almost the whole length of the building, and on this is worked "Borough of Luton Electric Lighting Station." The parapets are surmounted by Bath stone copings with richly-worked pinnacles at feet and apices of the gables. Between the two main gables is placed a large stone panel surmounted by a Grecian double shell hood. On the panel is emblazoned the representation of the borough arms in full relief. The front entrance hall is 8ft. 6in. wide by 16ft. in depth, and floored with pitch-pine wood blocks laid to special design. The walls have a dado of glazed tiles, also of special design. To the left is the drawing office, 20ft. by 16ft., with a floor of similar construction. Communicating with this is the workshop, fitted up with benches, etc.; this room is 20ft. by 16ft., and floored with granolithic paving.

Leaving the workshop, one enters the accumulator-room, 53ft. 6in. by 20ft., with its acid-proof floor laid to gradients, and with channels for quick cleansing. This room is well ventilated by lead-covered louvre frames. The engine-room is next to and communicating with the accumulator-room. Its size is 30ft. by 46ft., and will contain three high-speed engines, each of 1,351 h.p., and dynamos, each 85 kw., with space for future extensions. Here will also be the condensing plant and superheater and steam 42-kw. balancing set with 16-kw. charging dynamo, together with an excellent switchboard and insulating pads and stand. The machinery is to be of the most modern type, and supplied by the best makers. The walls of this room are lined with best white glazed bricks up to about 17ft. in height, and it has a dado of a darker colour of same material, and recessed, having moulded arches over the panels thus formed. The pilasters have moulded cappings, neckings, and bases. The travelling crane is carried on corbels of glazed bricks, running the full length of the room, to which are secured steel runners. This crane has a travelling capacity of six tons, ordinary load. Below the floor levers is a perfect network of pipe and cable trenches covered with iron plates. A clerestory is formed above the line of arcading, giving the north light, which is so desirable in a room of this kind. A skylight running the full length of the room is provided, and this performs the additional office of a ventilator. The height from floor to eaves is 22ft.

The boiler-house is 50ft. by 63ft., and communicates with the engine-house and front entrance hall. It also has a separate entrance in front elevation. Two Lancashire boilers and superheaters, each 30ft. by 8ft., are being placed therein, with economiser. All have special settings of new and approved design. The floor will consist of concrete with granolithic surface. The height from floor to plate is 18ft. The main flue of the boilers is kept at the upper end to allow for any future extension without disturbing the present structure. There is, however, a space reserved for another boiler of similar capacity to those already described, to be filled when occasion should arise. Adjoining the boiler-house is the pump-room, 16ft. by 10ft., which draws the supply of water for the boilers. Over this room is placed the large tank of 6,000 gallons capacity, with cooling tower and access ladder, in all weighing about 30 tons. Immediately communicating with the boiler-house are the coal bunkers, which are so arranged that they can have the coal discharged from ordinary wagons direct, or, if occasion should require, from a siding off the railway which might eventually be constructed. Mechanical stoking could also be applied. The wall of the boiler-house over the large opening into the coal bunkers is carried by an English steel riveted girder, 32ft. long. The material for flooring the pump-room and coal bunkers is precisely the same as used in the boiler-house. The coal bunkers are entered from without by large sliding doors.

The first floor, on which is the chief engineer's office, is reached from the entrance hall by a fire-resisting staircase and landings, having ornamental wrought-iron balusters and richly-moulded mahogany handrail and newel. The latter will be surmounted by a beautifully designed electric lamp. This office is over the drawing office, and is of the same dimensions, being ventilated, lighted, and heated in a similar manner to the room below. The cornices and enrichments will be of special design. This room communicates with a balcony overhanging part of the engine-room, and commands a complete view of everything therein. The second floor, on which are the meter stores, is reached by the continuation of the fire-resisting staircase already described. The buildings are covered with best brindled Broseley tiles on specially designed roof principals, all made of best English steel. A lantern running the full length of the building is constructed in the roof of the boiler-house, having glazed roof, and louvres at the sides for ventilation. The height from the boiler-house floor to this ridge is about 40ft.

The chimney shaft, which stands in the angle formed by the boiler-house and pump-room, but at the same time wholly detached from the main walls, runs to a height of 120ft. above ground level, and weighs about 75 tons; it stands on a bed of solid concrete 25ft. by 16ft. thick. Considerable difficulty was experienced in the process of excavating for the chimney bed, owing to the soft nature of the soil, which necessitated close piles being driven right through to the solid bottom. A good foundation was found at a depth of 25ft. below the surface. The shaft is built to a batter of 1 in 40 with Luton bricks, and lined with firebricks to half its height, with an intervening cavity of 2½in. inside. The whole is built in English bond, and capable of resisting a wind pressure of 42lb. to the square foot. The draught is equal to about 2,000 h.p., which can be considerably increased by forced draught. The shaft is surmounted by moulded necking and corbelled cornices in selected Ibstock bricks, and covered with a cast-iron cap, in sections, bolted together, and weighing 2½ tons. The chimney commences with a square base, and at a height of 26ft. an octagon is formed with broaches at angles of bed. The octagonal form continues to the summit.

At the lower end of the site a cooling pond is to be constructed, and the water from the Lea is to be used for condensing purposes. A few yards away to the north of this pond a well is to be sunk. This well will provide a constant supply of water for the boilers, which is pumped from here to the tank before mentioned over the pump-room. The position of the buildings is so arranged as to admit of very large extensions for the future. A road 36ft. wide is to be formed at the south side of the building, allowing room for carts and trucks, should a siding be constructed. The whole of the foundations, engine and boiler beds, etc., drainage and road-making, will be executed by the Corporation workmen, at an estimated cost of £1,400. The builders are Messrs. Neville Bros., Luton, whose contract amounts to £4,881.

The buildings were designed and will be carried out by the borough engineer (Mr. A. J. L. Evans); the whole of the

Digitized by Google

electrical plant, etc., by Mr. Albion T. Snell, consulting engineer, London.

A HIGH-VOLTAGE WALL PLUG.

The change from low-voltage to high-voltage supply has instigated the manufacturers to pay special attention to accessories suitable for the thus increased voltage, and we have before us a new wall plug, manufactured by the International Electric Company, of 55, Redcross-street, Barbican, London,

E.C., for which it is claimed that as far as insulation is concerned it will answer even the most stringent stipulations of central-station engineers. With this plug arcing, or short-circuiting is stated to be an impossibility, as all the current-carrying parts are deeply embedded in china, and surrounded by the same material, no metal parts being at the back of the china base. The plug itself is provided with a patent porcelain cord grip, and from the point of view of safety the article seems to fulfil all that is claimed by the manufacturers. The plug, of which we give illustrations, is exceedingly cheap, being sold at only 15s. per dozen. We are informed that central-station

engineers and others who are interested can obtain samples free of charge on sending a post-card to the firm.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Rochdale.—Tenders for the supply and fixing of a lift at the infirmary, to be worked by electricity, will probably be advertised shortly.

Hampstead.—The Vestry invite tenders for various plant for their central station, Lithos-road, Finchley road. Tenders by Sept. 27.

Piatra Neamtz (Roumania).—The Municipality invite tenders for the lighting of the town by electricity for 30 years by Nov. 2 concession).

Hoylake and West Kirby.—The Urban District Council invite tenders for wiring premises. Tenders by Oct. 4. Details in our advertisement columns.

Philippopolis (Bulgaria).—The Town Council invite tenders for erection and working of electric lighting and working of tramways. Tenders by Nov. 4 (concession).

Hackney.—The Electric Lighting Committee of the Vestry invite tenders for electricity supply mains. Tenders by Oct. 3. Details in our advertisement columns.

Birkenhead.—The Corporation invite tenders for the supply, delivery, and laying of feeder mains, etc. Tenders by Oct. 2. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for the supply of cast-iron bases for tramway poles. Tenders by Oct. 1. Details in our advertisement columns.

Santiago.—Offers are invited for the laying down and working of a telephone system in Santiago de Compostela, in the province of Coruna, Spain. Tenders by Oct. 19.

Azuaga.—Offers are requested by the Municipality of this town, in the province of Badajoz, Spain, for the installation and working of the electric light for 20 years. Tenders by Oct. 11.

Melton (Suffolk).—The Visiting Committee of the Suffolk County Lunatic Asylum invite tenders for wiring and fittings. Tenders by Oct. 5. Details in our advertisement columns.

Fuenteovejuna.—Offers are requested by the Municipality of this town, in the province of Cordoba, Spain, for the installation and working of the electric light for 20 years. Tenders by Oct. 9.

Manchester.—The Directors of the Lancashire and Yorkshire Railway Company invite tenders for the supply of various stores. Tenders by 10 a.m. on Oct. 8. Particulars in our advertisement columns.

Ilford.—The Urban District Council invite tenders for meters (direct-current) and cut-outs. Specification may be obtained from Mr. J. W. Benton, clerk, Council Offices, Cranbrook-road, Ilford. Tenders by Oct. 8.

Horton (Surrey).—The Asylums Committee of the London County Council invite tenders for the installation of boilers, engines, dynamos, etc, at the Horton Estate, Epsom, Surrey. Tenders by Sept. 22.

Whitehaven.—The Water and Lighting Committee of the Corporation invite tenders for the supply and erection of a switchboard at their electric lighting station. Tenders by Oct. 13. Details in our advertisement columns.

Fulham.—The Vestry invite tenders for the supply and erection of plant for unloading and storing coal at their electric lighting works, Townmead road, Fulham. Tenders by Sept. 25. Details in our advertisement columns.

Wigan.—The Corporation invite tenders for steel poles, section pillars, flexible bonds, trolley wire, overhead construction material, bracket arms, and castings. Tenders by 25th inst. Details in our advertisement columns.

Hull.—The Electric Lighting Committee invite tenders for steam and water pipes, feed pump, water softener, etc., at their Sculcoates-lane generating station. Tenders by Sept. 27. Full details in our advertisement columns.

Aberdeen.—The Tramways Committee invite tenders for the manufacture and supply of 25 electrical tramcars, and equipments for six horse cars, about to be converted. Tenders by Oct. 17. Details in our advertisement columns.

Dublin.—The Corporation invite tenders for electric motors and pumps for Ringsend drainage works. Specifications may be obtained at the office of the consulting engineer, Mr. Chatterton, 6, The Sanctuary, Westminster. Tenders by Oct. 3.

Tunbridge Wells.—The Corporation invite tenders for erection of an octagonal brick chimney shaft, 180ft. in height, at their central electric light station, adjoining S. E. and C. Railway goods station, Tunbridge Wells. Tenders by Sept. 24.

Bradford.—The Corporation invite tenders for the construction and delivery of an engine and dynamo, also switchboard apparatus, etc., for their destructor works, Southfield-lane, Bradford. Tenders by Oct. 9. Particulars in our advertisement columns.

Limerick.—The Town Council invite tenders for erection and completion of an electric generating station building at Frederick-street, Limerick. Drawings and specification may be seen at the office of Mr. J. J. Peacocke, B.E., city surveyor, Town Hall, Limerick. Tenders by Oct. 4.

Walthamstow.—The Council invite tenders for the supply, delivery, and erection of electric lighting plant and apparatus, consisting of gas plant, gas engines, dynamos, switchboard, booster, balancer, and measuring instruments. Tenders by Sept. 25. Details in our advertisement columns.

Bray.—The Urban District Council invite tenders for supplies required at their electric light works for 12 months, including cables, carbons, house wires, switches, lampholders, incandescent lamps, etc. Particulars may be obtained from Mr. P. MacDonnell, clerk of the Council, Town Hall. Tenders by Oct. 4.

Eastbourne.—The Corporation invite tenders for the supply and erection of a water-tube boiler, with fittings, feed pump, etc., a 400-kw. steam alternator, with exciter (vertical enclosed high-speed engine), and main switchboard and connections. Tenders by Oct. 4. Particulars appear in our advertisement columns.

Sheffield.—The Corporation invite tenders for specification No. 3 (a) two two-phase steam alternators and exciters, 600 kw.

Digitized by Google

each; (b) alteration of present single-phase plant to two-phase. Specifications can be obtained from Mr. S. E. Fedden, chief engineer and manager, Commercial-street, Sheffield. Tenders by Oct. 6.

Devonport.—The Corporation invite tenders for supply and erection of (Part 1) two vertical engines; (2) two 300 kw. generators, balancer, battery, booster, and motor; (3) switchboard for electric lighting and traction; storage battery and travelling crane (10 ton). Tenders by Sept. 26. Details in our advertisement columns.

Dundee.—The Dundee Gas Commissioners invite tenders for: (1) overhead travelling crane; (2) economiser; to be supplied and erected at the electric lighting station, Dundee. Specifications, plans, and forms of tender may be had on application to Mr. Walter H. Tittensor, city electrical engineer, Dunhope-crescent-road, Dundee. Tenders by 26th inst.

London, S.W.—The London County Council invite tenders for the supply within 12 weeks of the order being given of the mains required in connection with the electric light installation for the Victoria embankment and Westminster Bridge. Particulars may be obtained at the Engineer's Department, County Hall, Spring-gardens, S.W. Tenders by 24th inst.

Brighton.—The Council invite tenders for the supply and delivery of 2,000 tons of steel girder tramrails, 78 tons of steel fishplates, 90 tons of steel joists. Specifications and form of tender and all necessary information may be obtained on application at the office of Mr. Thos. B. Holliday, tramways engineer, Town Hall, Brighton. Tenders by Oct. 1.

Aberdeen.—The Electric Lighting Committee invite tenders for supply of (1) two 200-kw. direct-coupled continuous-current generators and one 120-kw. balancing set; (2) one 420-kw. direct-coupled continuous-current generator. Specification and form of tender can be obtained from Mr. J. Alex. Bell, city electrical engineer, Cotton-street, Aberdeen. Tenders by Sept. 29.

Dublin.—The Electric Lighting Committee of the Corporation invite tenders for the supply and laying of electricity supply mains and accessories. Specifications and form of tender may be inspected at the office of the city engineer, Mr. Spencer Harty, M.I.C.E., City Hall, Dublin, and at the offices of Mr. R. Hammond, consulting engineer to the Corporation, 64, Victoria-street, S.W. Tenders by Oct. 4.

Medomsley (Durham).—The Parish Council invite tenders for the supply and erection of electric lamps, posts, cables, etc., necessary for the lighting of the road leading from Black Hall Mill to Medomsley Village, via Westwood Colliery. Particulars may be obtained from Mr. M. T. Milburn, Medomsley, R.S.O., clerk to the Council, and the ground may be viewed on making an appointment by letter.

Brighton.—The Corporation invite tenders for the supply and delivery of 25 electric motorcars. The work is divided into three sections, and contractors may tender in respect of all or any one or more of such sections—viz.: (Section 1) 25 electric motorcar bodies; (2) 25 electric motor trucks; (3) 25 electric motor electrical equipments. The specification and form of tender and all necessary information may be obtained on application at the office of the tramways engineer, Mr. Thos. B. Holliday, Town Hall, Brighton. Tenders by Oct. 1.

Long Eaton.—The District Council invite tenders for the construction of a line of poles, also two wires (about 5·10 miles in length), with other accessories, for the purpose of establishing a telephonic and electro-mechanical transmitting and registering and recording apparatus between their waterworks pumping station at Stanton-by-Bridge, near Derby, and the service reservoir at Castle Donington, Leicestershire. Plan may be seen at the offices of the Council, Long Eaton, and specification, with form of tender, obtained on application to Mr. Frank Worrall, surveyor and waterworks manager, Council Offices, Long Eaton. Tenders by Oct. 1.

RESULTS OF TENDERS.

Heywood.—The Corporation have accepted the tender of Messrs. Crompton and Co., Limited, for the supply of plant for the electricity works at £8,389. 15s. 1d.

Aberdeen.—The Tramways Committee have accepted the tender of Macartney, M'Elroy, and Co., Limited, amounting to £6 597. 19s. 10d., for the supply of tramway poles, etc.

Leeds.—The contract for the iron and steel work for the boiler-house has been let to Messrs. Clayton, Son, and Co., Hunslet, and the building trades' contract to Messrs. Irwin and Co., Burley-road. The amount of the contracts is a little over £10,000.

Kensington.—The Hart Accumulator Company, Limited, Marshgate-lane, Stratford, have secured the contract for the supply of storage battery required by the Committee of Management of the Kensington and Notting Hill electric lighting for use in the lighting of their Wood-lane works.

Birkenhead.—The Corporation have accepted the tender of Mr. J. Merritt, Adelphi-street, for constructing and erecting a new car-shed in connection with the electric tramways in Laird-street, at £10,183; and the tender of Mr. W. R. Holland, Dacre-street, for alterations and additions to the tramway car-sheds, New Ferry, at £995.

Ilford.—The Urban District Council have accepted the tender and designs of S. Pontifex and Co. for lamp columns—viz., for 20 of No. 5 of the patterns submitted, weighing 2cwt. 3qr., 10ft. high, to be delivered for 30s. each. They have asked Messrs. Pontifex and Co. to quote for lots of 200, 300, 400, and 500 lamp columns.

Aberdeen.—The Town Council have accepted the following tenders: P. and W. McLellan, Glasgow, straight and curved rails, £7. 13s. 9d. per ton; P. and W. McLellan, fishplates, £8. 13s. 9d. per ton; Bayliss, Jones, and Bayliss, Wolverhampton, bolts and nuts, £16. 10s. per ton; A. and J. Main and Co., Possilpark, Glasgow, tiebars, £12. 7s. 6d. per ton.

Bradford.—The Guardians have accepted the following tenders in connection with the electric lighting of the workhouse: C. A. Parsons and Co., Section No. 1, £900; Electrical Power Storage Company, Section No. 3, £1,025; G. A. Steinthal, Section No. 4, £308; G. F. Cook and Co., Section No. 5, £613; C. A Parsons and Co., for steam separator and steam trap, £20.

Newcastle-on-Tyne.—The Corporation have accepted the following tenders: Mather and Platt, Limited, Salford Ironworks, Manchester, for erection of pumping plant for condensing water at the generating station, £1,470; J. J. Robson, Osborne-road, Newcastle, for carrying out the western section of the new electric tramways (Blackett-street, Gallowgate, Barrack-road, Stanhope-street, Westmoreland-road, and Hamsterley-road), £24 505; E. Nuttall, Manchester, for carrying out the eastern section of the new electric tramways (City-road, Walker-road, Raby-street, and Heaton-road), £26,072. 5s.

Tunbridge Wells.—The Town Council have accepted the following tenders for carrying out telephone installation: Henley's Telegraph Works Company, supplying, laying, and jointing of armoured telephone cables, £2,373. 10s.: Reid Bros., erecting and staying poles, wires, arms, insulators, etc., £1,080; General Electric Company, telephone instruments, £843; Wade and Co., creosoted poles, £702. 2s. 3d.; Bolton and Sons, hard copper wire, £518. 2s. 1d.; Telegraph Manufacturing Company, switchboard, £282. 15s. 6d., insulated wires £218. 10s.; General Electric Company, insulators, £216. 19s. 8d.; International Electric Company, lightning arresters and high-tension guards, £102. 1s.; Bullers, Limited, miscellaneous ironwork, £97. 2s. 2d.; Aspden and Co., oak arms, £64. 1s. 2d.; Dennis and Co., iron and steel stay wire, £37. 15s.; India Rubber, Gutta Percha, and Telegraph Works Company, batteries, £35. 5s.; Bolton and Co., soft copper wire, £21. 11s. 8d.; Potter and Co., arm bolts, nuts, and washers, £10.

BUSINESS NOTES.

TRACTION.

Folkestone.—The General Purposes Committee have decided to recommend an electric tramway sceeme, involving an outlay of £95,000.

Lambeth.—The Vestry have declined to contribute towards the cost of widening certain streets by the London County Council in order to construct tramways.

Ince.—The District Council have appointed a deputation to confer with the Hindley and Pemberton Councils upon the question of the purchase of the tramways within their district.

Huddersfield.—At the meeting of the Town Council on Wednesday the Tramways Committee proposed that tramway works be carried out by July 1 next to the amount of £68,953. 6s. 11d.

Sunderland.—The Tramways Committee's former minute relating to the application to the Board of Trade for permission to lay a double line of tramways in Vine-place has been rescinded.

Swinton.—A special meeting of the District Council will be held on Oct. 8 to consider the question of the purchase from the Manchester Carriage Company of the tramways within the district.

Ilford.—The Board of Trade have determined that the tramways authorised by their recent order shall be constructed on a gauge of 4ft. 8½in., and that no engine or carriage is to exceed 6ft. in width.

Ipswich.—Notice will be served upon the Ipswich Tramways Company requiring that company to sell the undertaking authorised by the Ipswich Tramways Order, 1879, to the Corporation of Ipswich.

North London.—A rumour, the source of which we have not been able to trace, is to the effect that an underground electric line from Liverpool-street to Romford is to form the basis of a Bill in the next session.

Torquay.—Mr. J. Taylor's scheme for five miles of electric tramway has been referred to a small sub-committee, who will consider the details and report. The cost of the scheme is roughly estimated at about £50,000.

Reddish.—The Urban District Council's parliamentary expenses incurred in obtaining a provisional order for the construction of a tramway through the district, extending from the Stockport borough boundary to the Gorton boundary, amount to over £560.

Wednesbury.—Notice will be given to the South Staffordshire Tramways Company requiring them to sell to the Council so much of the tramway undertaking as is within the borough of Wednesbury, and as was authorised by the Staffordshire Tramways Order, 1879.

Oberammergau.—According to a recent note in the *Globe*, the Passion Play at Oberammergau has been a great success from various points of view. Since May 24 the electric branch railway line from Murnan to Oberammergau has earned total receipts amounting to £21,222.

Leeds.—The new engines in course of erection at the generating station at Crown Point will be supplied with steam from nine boilers, each 30ft. in length and 8ft. in diameter. The boiler-

Digitized by Google

house will have a second storey which will form a coal store, where 2,000 tons of coal can be stored for an emergency.

Dundee.—Three additional electric bogie cars for the Lochee route have arrived in the city, and are being fitted up to be ready for the Board of Trade inspection of the line on the 27th inst. The Board of Trade have consented to the speed of the cars on the High-street and Nethergate being increased from four to six miles an hour.

Windermere.—The local opposition to the Windermere and district light railway scheme has resulted in the withdrawal of the present application to the Light Railway Commissioners. It is, however, stated that the British Electric Traction Company have made agreements with the local authorities, and will bring forward in November another application.

Hull.—A movement is in progress among the Corporation's electric tramway employés for an eight hours' continuous working day and an alternate Sunday off, or time and a half pay. The Tramways Sub-Committee have the matter in hand, and are endeavouring to obtain information from other large towns as to the working conditions of tramway employés.

Brighton.—The Tramways Committee of the Town Council have decided to take electricity from the Corporation supply for working the tramways at 5d. per unit for the first hour's consumption and 1d. per unit afterwards, and have asked the Lighting Committee to be ready to supply the current by Aug. 1 next. The estimated cost of wood paving the tramway area is £44,067. 16s.

Stourbridge.—Trial trips have been made along the Kingswinford electric tramway during the last few days, and the line will probably soon be opened for public use. Several new cars for this and connected branches have just been delivered at the Stourbridge goods depôt. They are two-deckers, and will carry 65 instead of 28 passengers each, as is the case with the present cars.

Cardiff.—Mr. Ellis, who has within the past week taken up his post, has submitted a report, in which he points out the short time that remains in which to accomplish a good deal of work. As a site for the generating station, Mr. Ellis recommends the committee to secure the Heath Brook site. The committee have come to an agreement to purchase land adjoining the scheduled site, which will enable the work to go on immediately.

Paisley.—The draft tramway order as brought forward by Bailie Bell has been remitted to committee for consideration and report. The cost of the scheme, which is practically the same as that promoted by Mr. Murphy, with the exceptions of the line to Meiklerigge and the extension of the line in Johnstone, is estimated at £200,000. This includes provision for 30 cars and the necessary sheds, £12,000 for the additional electric plant required, with 7 per cent. added to meet contingencies.

Devonport.—The Borough Council have adopted a report of the Tramways Committee recommending that the Corporation construct the lines authorised by the order of 1899 and the Act of 1900 if satisfactory arrangements are come to with the Devonport and District Tramways Company for the working thereof; and, further, that the town clerk be instructed to make an application to the Board of Trade for an extension by 12 months of the time within which the tramway may be commenced and completed.

Hyde.—The Stalybridge, Hyde, Mossley, and Dukinfield Electric Traction and Lighting Joint Committee have agreed to apply for an Act to carry out a proposed joint electric traction and lighting scheme. The capital required for the purposes of the scheme is to be raised by calls in a similar manner to the capital raised under the Ashton-under-Lyne, Stalybridge, and Dukinfield (District) Waterworks Acts, each corporation to contribute £100 towards the general expenses. The Council have ratified the committee's proceedings.

Twickenham.—The London United Tramways Company have written to the Council stating that the attention of the directors had been drawn to the proposed raiding of the district by a scheme of light railways on the part of the Middlesex County Council, and that the directors were prepared to entertain any proposed extensions of the London United system that may be deemed expedient. The Council have agreed to give their careful consideration to any further extensions of the London United system in the district which the company might desire to lay before them.

Holland.—A company has been formed, with the beautiful and simple name of the Zuid-Hollandsche Elektrische Spoorweg Maatschappij, for the purpose of constructing an electric railway to connect Rotterdam with the Hague and Scheveningen. The authorised capital is £300,000 of ordinary shares and £400,000 of obligations, and of the latter £100,000 in 4½ per cents. are now being issued in Amsterdam and Rotterdam. It is reported that the whole of the plant for the railway and all the electrical machinery have been ordered from Messrs. Siemens and Halske, of Berlin.

Sheffield.—A memorial has been presented to the Corporation, asking that in any continuance of the tramway on the Ecclesall-road route hardwood may be placed on either side of the rails. A similar memorial has been presented by the inhabitants of Fulwood-road and district. The matter was brought to the attention of the City Council at its meeting last week, but the chairman of the Tramways Committee said that neither the Highway nor his own committee had considered the matter, and he forebore giving his opinion, as he did not want to pledge the Tramways Committee without their authority.

Esher and the Dittons.—The London United Tramways Company intend to apply for powers to make and work a tramway from their boundary on the Portsmouth-road, Long Ditton, to High-street, Esher, and from Long Ditton, *viâ* St. Leonard's-road and Summer-road to Hampton Court Bridge. The Council will oppose any tramway being made in the district, but they decided last week that it would not be wise to bind themselves with Kingston in their application to the House of Commons, or with Surbiton, who were also anxious to get their help. The successful opposition to the light railway proposed by the British Electric Traction Company gave rise to a vote of thanks to the chairman.

Southend.—Great are the ways of red-tape! At a recent meeting of the Town Council the Electric Lighting Committee reported that an application had been made to the Local Government Board for sanction under the provisions of the light railways order to the use by the Corporation of the land at the rear of London-road, adjoining the Corporation's depôt, as a site for car-sheds and generating station, etc. The Local Government Board having doubts as to their powers in the matter, the Board were interviewed, when the town clerk suggested the difficulty might be overcome by the Corporation selling the land as superfluous land and then repurchasing. No objection to the proposal had been made, and the committee asked for an authorisation to do what was necessary. This was agreed to.

Wandsworth.—The Board of Works have received notice from the London United Tramways, Limited, of intention to apply for powers in the coming session of Parliament to construct the following tramways: Commencing at Hammersmith-broadway and passing along Queen-street, Fulham Palace-road, High-street, over Putney Bridge, High-street, Putney, Putney-hill, Kingston-road, and Kingston-hill, London-road, Clarence-street, over Kingston Bridge to a junction with authorised tramways at Hampton Wick. Also commencing at the junction of High-street, Putney, and Upper Richmond-road, along Upper Richmond-road, and Sheen-road, to Richmond. This communication is now being considered by the General Purposes Committee.

Govan.—The Tramway Committee of the Glasgow Corporation have agreed to recommend that the previous arrangement be amended, so far as applicable to Govan, as follows—viz., that in equipping the tramways in Govan-road from Linthouse to a point east of Whitefield-road, so far as is necessary to give a clear access to the 130-ton crane at Prince's Dock, for electric traction, the overhead construction should be so arranged as to permit, when the necessity arises, for taking any boiler or large piece of machinery along the Govan road, of a clear headway of 23ft. being given in the centre of the street above the level of the tramway rails, instead of at the side of the street, it being understood that the engineers and boilermakers shall use as low a bogie as it is possible to construct when conveying any boiler or other machinery of unusual dimensions along the streets.

Bolton.—At a recent meeting of the Tramways Committee a letter was read from the Turton Urban District Council, asking whether the Corporation would be willing to lease and work as a portion of their system a line between the Royal Oak and Bradshaw, and Dunscar Bridge, and upon what terms. The matter was referred to the borough engineer and electrical engineer to report upon. The borough surveyor was requested to prepare plans for the improvement of the curves of the tramlines at the junction of Knowsley-street and St. George's-road. Lieut.-Colonel Von Donop was to hold an enquiry on the 19th inst. into the application of the Corporation for powers to borrow money for tramways purposes. The borough engineer is preparing plans and estimates of the cost of laying double lines on the whole of the track where practicable, and the Board of Trade have been requested to postpone the enquiry.

Fulham.—The Vestry have received the following letter from the engineer of the London United Tramways Company, Limited: "I beg to inform you that it is the intention of this company to apply in the coming session of Parliament for powers to construct tramways in the parish of Fulham. A tramway commencing at Hammersmith-broadway, and passing along Queen-street, Fulham Palace-road, High-street, over Putney Bridge, High street, Putney, Putney-hill, Kingston-road, and Kingston hill, London-road, Clarence-street, over Kingston Bridge to a junction with authorised tramways at Hampton Wick, making a route mileage in your parish of about 1¾ miles. There will be certain improvements, street widenings, etc., involved in the construction of these tramways, which it will be my pleasure to explain and discuss with your committee at any time which they may make convenient for the purpose between now and the date fixed for making the parliamentary deposits."

New London Electric Railway Scheme.—According to the *Times*, negotiations are practically completed by which the construction of the long-projected railway from Charing Cross to Hampstead will be almost immediately commenced. It is stated that Mr. A. E. Gathorne Hardy, Lord Verulam, Sir D. L. Salomons, Sir E. Leigh-Pemberton, and Mr. J. Browne Martin, who have been acting as directors, have recently retired in connection with the negotiations referred to, and that a new Board will be appointed next week by Mr. Yerkes. The length of the projected line, including the branch to Kentish Town, is about 6½ miles and the total expenditure on the undertaking is estimated by Mr. Housman at between £3 000 000 and £4,000,000. The engineers are Sir Douglas Fox and Mr. W. R. Galbraith, and the solicitor is Mr. Perks, M.P. Mr. Housman will return to New York on the 29th of this month and Mr. Yerkes on Oct 6, but Mr. Davis will remain in London in connection with the scheme.

Thames Ditton.—The Highways and Drainage Committee reported at last week's meeting of the District Council as follows: "A letter was received from Mr. J. Clifton Robinson, stating that attention had been drawn to a proposed scheme of light railways to be promoted by the Middlesex County Council,

Digitized by Google

and stating that his directors were prepared to entertain any further extensions of the scheme in this Council's district which may be deemed expedient. The clerk was instructed to reply that the committee had not received any intimation from the County Council on the subject, and that if the tramways company had any proposals to make the committee would be glad to receive particulars thereof as soon as possible. A letter was received from the surveyor of the Middlesex County Council stating that the London United Tramways Company had submitted plans of the work they proposed to carry out on the portion of main roads within the District Council's district, and that before taking any steps in the matter of approval or disapproval of the plans and the materials proposed to be used, he would be glad to know the views of the District Council with respect to the kind of materials to be used. It was resolved to reply that the Council would require the company to pave, maintain, and repair with hardwood blocks the portion of the roadway which the company are required to maintain and repair under Section 28 of the Tramways Act, 1870, and also the remainder of the roadway in places where the tramway shall be situate within 3ft. of either kerb."

LIGHTING AND GENERAL.

Whitehaven.—The Town Council are taking steps to popularise the use of electric light.

Fallowfield.—The postal authorities are being asked to provide a telegraph office at Fallowfield.

Bangor.—It is reported that the electric light works will be ready by the middle of October at latest.

Trowbridge.—It appears that at present 144 replies have been received from householders willing to take current.

Grantham.—The Town Council are considering the advisability of establishing in the town the municipal telephone system.

Devonport.—Sanction has been obtained to loans of £15,250 for land and £52 700 for works in connection with the electric supply scheme.

Bedford.—The Town Council have decided to increase the price of electric current by 1d. per unit, giving six months' notice to Michaelmas.

Colwyn Bay.—The works by the contractors for both the machinery and buildings for the electric light installation are making progress.

Ince.—A meeting of the District Council is to be held on Oct. 8 to consider the advisability of applying for an electric lighting provisional order.

Walsall.—The Council propose to purchase 542 square yards of freehold land in Pleck-road, for the sum of £130, as a site for a transformer station.

Teddington.—The District Council have decided to engage a parliamentary agent for the purpose of applying for a provisional order for electric lighting.

Millarew.—The North British Electric Supply Company intend to obtain powers to supply with electrical energy the area over which the Council has jurisdiction.

Truro.—The report of Mr. Headley, electrical engineer, St. Austell, on the suggested lighting of the city by electricity, is under consideration by the Council.

Amazonia Rubber and Trading Co.—The directors have declared an interim dividend for the current year on the preference and ordinary shares at the rate of 10s. per share.

New Branch.—The British Thomson-Houston Company, Limited, of 83, Cannon-street, E.C., have recently opened a branch office in Manchester, in the Trevelyan-buildings, Corporation-street.

Barnet.—The North Metropolitan Electrical Power Distribution Company, Limited, started supply on Sept. 1, that being the date specified in their agreement with the Council for lighting the streets.

Barrow.—The Council have adopted a report from Messrs. Kincaid, Waller, and Manville in connection with the further application for sanction to borrow £6,690 for the purposes of electric lighting.

Stock Exchange.—The committee have been asked to allow the Aron Electricity Meter, Limited, 125,000 ordinary shares of £1 each, fully paid, Nos. 1 to 125,000 (special application), to be quoted in the official list.

Heywood.—At the last meeting of the Council it was stated that the tender for the plant at the electricity works amounted to £8,389. 15s. 1d., and it comprised all that was required from an engineering firm.

Swanage.—Letters from the Bournemouth and Poole Electricity Supply Company with regard to their application for a provisional order for the lighting of Swanage have been referred to a committee of the whole Council.

Electric Incandescent Lamp Regenerating Syndicate, Limited. This Company has been registered, Sept. 8, with a capital of £7,500, the object being to carry on the business of electrical engineers, manufacturers, etc.

Ashton.—The sub-committee appointed to visit and inspect electricity stations with a view of ascertaining the best makers and description of generating plant have visited Messrs. Musgraves and the Bolton Corporation electricity works.

Dollar.—The Burgh Commissioners have signed a provisional agreement with the electric company for the electric lighting of the burgh. The minimum number of lamps to be required has been fixed at two arc and 12 incandescent lamps.

Wisbech.—The Town Council are considering the expediency of applying to the Board of Trade in the ensuing session of Parliament for a provisional order to enable them to supply electricity for all public and private purposes throughout the borough.

Direct Spanish Telegraph Co.—The directors announce, in addition to the dividend at the rate of 10 per cent. per annum on the preference shares, an interim dividend at the rate of 4 per cent. on the ordinary shares for the half-year ended June 30.

Paris Exhibition Awards.—The awards given to the firm of Stern Bros., of London and Glasgow, makers of the Fram lubricant, and inadvertedly referred to as having been made in respect to lamps, were awarded for refined lubricating oils and greases and lubricators made by that firm.

Taunton.—The agreement between the Corporation and the National Electric Wiring Company has been terminated, owing to difficulties with regard to the arrangement for payment by the Corporation of a minimum charge. Arrangements are being made whereby the consumers can purchase their installations.

New Agency.—The British Thomson-Houston Company, Limited, of 83, Cannon street, London, E.C., have appointed Mr. J. W. Sheffield as their district manager of the branch depôt recently opened at Trevelyan-buildings, Corporation-street, Manchester, for the sale of electrical apparatus and general supplies.

Scothill Nether.—Representatives from the Northern Counties Electric Supply Company waited upon the District Council last week, and discussed the terms upon which the company would be prepared to apply for necessary powers to enable electricity to be supplied to the Council's district. The matter was left over for further consideration.

Kingswinford.—The deed of transfer of the Kingswinford Electric Lighting Order, 1898, as settled by the Board of Trade, was approved at the last meeting of the Urban District Council. The Clerk reported that the Council had been served with a notice in which the company expressed their desire to press on with the work of laying the mains.

New China Cable.—The Great Northern Telegraph Company and the Eastern Extension Telegraph Company on the 17th inst. completed the laying of the Shanghai-Chi-fu cable, placing Chi-fu, Taku, Port Arthur, and We-hai-wei in direct communication with the central station of the Great Northern Telegraph Company, and thus rendering those places independent of the Chinese land lines.

King's Lynn.—The electrical engineer's last report states that the number of applications for the supply of current is now 213, representing an equivalent of 6,696 lamps of 8 c.p., an increase of 232 lamps during the month. The offer of the committee to the Electrical Chloride Syndicate not having been accepted, Major Cardew has been nominated as arbitrator to deal with the matter.

New Brancepeth Colliery.—A meeting of the Lighting Committee of the Brandon and Byshottles Urban District Council was held at New Brancepeth Colliery last week, when the chairman of the Council, Mr. W. Willis, switched on the electric light for the first time. Twenty-seven electric lamps have been fixed in the public streets. Mr. J. J. Spoor, of Bishop Auckland, was the contractor.

Aberdeen.—The Town Council on Monday resolved that the present salary paid to Mr. J. A. Bell, the electrical engineer, should be increased by annual increments of £50 till it reaches £500 per annum. At the same meeting it was decided to spend £6,600 in constructing a subway for feeder and pilot cables which it will be necessary to lay from the new electric station at Dee village to the different feeding points.

Accident.—A lineman in the employment of the National Telephone Company lost his life at Aberdeen last week owing to the collapse of a standard which several men were engaged in erecting on a block of buildings in Holborn-street. The guy rope at the front of the building broke, and the man was precipitated to the ground with the standard, a distance of 81ft. He died after being admitted to the Royal Infirmary.

Rochdale.—The New Infirmary Committee have agreed that the wiring for lighting the new infirmary be done under the supervision of Mr. Senior, workhouse engineer, the clerk to get prices for the wires and tubing. It is also proposed that the union offices be lighted by electricity by the Rochdale Corporation. The method of installation, etc., has been referred to a sub-committee, which will consult with the workhouse engineer.

Fraud.—William Neal, 38, storekeeper, was convicted on the 13th inst. at Marlborough-street police court for fraudulently obtaining from West-end firms subscriptions towards an outing for the workpeople of the National Telephone Company. Detective West said that Neal had collected £21. 19s. and appropriated it. The "outing" existed only in his imagination. Prisoner pleaded guilty, and said he had done it as he was out of work. Mr. Fenwick sentenced him to a month's hard labour.

Camborne.—As the provisional order for the supply of electricity for public and private purposes in this district obtained in July, 1898, by the Camborne Electricity Company has been purchased by the Camborne and Redruth Tramway Company, negotiations will now be opened by the Council with the company with a view of ascertaining the fullest information as to the conditions, etc., for the supply of electric light for the street lamps, commencing, if possible, on Sept. 1, 1901.

Durham.—We learn that the mains of the Electrical Power Distribution Company, who have taken over the provisional order for the electric lighting of the city, will be completed by about the end of the present month. The work has been somewhat retarded, as the company desire to await the result of the forthcoming

Digitized by Google

enquiry into the Durham, Neville's Cross, and Brandon light railway order, but we understand that the electric light will be available for the city in July or August next.

Knottingley.—Some time ago the Northern Counties Electric Supply Company gave notice that they were going to apply to the Board of Trade for a provisional order to supply the district with electricity for public and private use. The Rural District Council have now resolved to adopt electric lighting if it was found to be cheaper than gas. The clerk has been instructed to ascertain from various companies what the cost would be for public lighting; also the relative value of electricity and gas of 16 c.p.

Sproatley.—An agreement with the Sproatley Parish Council for the establishment of a telegraph office at Sproatley has just been signed. A guarantee of £27 per annum for seven years was required by the postal authorities. Half that amount has been guaranteed by the Parish Council, and the other has been guaranteed by private subscription. From the £27 guaranteed will be deducted all the receipts from telegrams handed in at the Sproatley office, and the guarantors will be called upon to make up only half of the balance remaining.

Enfield.—The Urban District Council have decided to apply for a provisional order for electric lighting in their district. A committee has been appointed to consider the proposals of the Edmonton Electricity Company, the United Electric Light and Traction Company, Limited, and the North Metropolitan Electric Power Distribution Company, and report as to whether it is desirable to enter into an arrangement with either of them, and if so upon what terms, or whether the interests of the district would be better served by proceeding with the promotion of the joint Bill.

Maidenhead.—The Council have adopted the following recommendations of the Electric Lighting Committee with regard to the recent enquiry into their application for £25,000 for purposes of electric lighting: (1) That so soon as the sanction of the Board is obtained the town clerk be authorised to apply to the Public Works Loan Commissioners for the amount sanctioned; (2) that the committee be empowered to instruct the consulting engineers to proceed with all necessary plans, specifications, quantities, and other matters, and to advertise for tenders for executing all the contemplated works.

London Gazette.—The following estates have been released from trusteeship: E. B. Pym, 29, Bramham-gardens, South Kensington, and E. M. Winter, Amberley House, Norfolk-street, Strand. The last day for receiving proofs in the estate of A. G. Inrig (trading as the Globe Electrical Company), 46, Whitepost-lane, Victoria Park, London, is Oct. 2; Mr. E. H. Hawkins, Wholesale Traders' Association, 3, Barbican, London, E.C., is the trustee. A first and final dividend of 2s. 1½d. per pound has been declared *re* H. Sewell, 63, Birklands-road, Shipley, Yorks, payable at Official Receiver's chambers, 31, Manor-row, Bradford, from Sept. 20.

Horsham.—At the last meeting of the Urban District Council the Electric Lighting Committee reported that they had considered the plan and estimate of cost of the proposed building for an electricity supply station, and had taken steps to get the estimate reduced. They now put the approximate cost of the building at £3,100, but stated that the work might possibly be done for £3,000. The committee recommended that the plans should be adopted, that tenders should be invited for carrying out the work, and that they be empowered to engage counsel to represent the Council at the Local Government Board enquiry. This was adopted.

Brechin.—The Angus Electric Lighting Company have submitted to the Police Commissioners a series of proposals to form a basis of an agreement for the lighting of the streets in which cables were to be laid. The company propose to use 16-c.p. incandescent lamps in place of the present lamps and to provide lamps, connections, etc., the present lamp-posts to be allowed to remain. They would also agree to undertake the lighting and extinguishing of the lamps at such hours as should be fixed by the Commissioners, the charge to be at the rate of £1 per 1,000 hours per lamp, which would be at the same rate as paid for gas lighting. The letter is now being considered by the Electric Light and Lighting Committee.

Worthington Pumping Engine Co.—This Company, which rejoices in various titles, one of which is Worthington Szivattygep Reezveny-Tarsasag, has just published a well got-up souvenir of the Paris Exhibition, giving details of 25 of their installations of engines distributed all over the Exhibition. With the exception of three cases, all these engines are to be seen at work. There are 17 pumps comprised in the exhibit at the Eiffel Tower in the American section. In the English section we find an independent compound and one independent triple-expansion condenser. The latter is designed for use with a Willans and Robinson engine of 2,500 h.p. The illustrations of the booklet are well executed, and it is rather interesting to compare thus the various types side by side.

Appointments Vacant.—An engine driver is required at the Corporation electricity works, Bedford.—The Bermondsey Vestry require the services of a resident electrical engineer. Full particulars of these vacancies appear in our advertisement columns. There are also required, for the Cape Government postal service, good Morse sounder clerks, with an average speed of not less than 30 words per minute. Applicants must be single, and not more than 25 years of age, and must bear good characters. The appointments are permanent. Salary £120 to £145 per annum, with an annual increase of £12. 10s. or £15, according to class. Free second-class passage out on signing for two years. There is a pension fund. Letters of application should be addressed to Messrs. Preece and Cardew, 13, Queen Anne's-gate, London, S.W.

Gosport.—The General Purposes Committee are considering a letter from the Corporation of Portsmouth enquiring if the Council had any objection to make to the application to be made to the Postmaster-General by the Portsmouth Corporation for the establishment of a municipal telephone exchange at Portsmouth, the area to be co-extensive with that of the Telephone Company, or if the Council would support the application. It is estimated that with the districts of Cosham, Gosport, and Fareham, and possibly Havant, included in the proposed exchange, 1,000 subscribers could be obtained, and that the price would thus be reduced to £5. 10s. per instrument. The Council are considering a proposal of the Electric Power Distribution Company to take over and work their electric lighting order and to develop the tramways.

Presentation.—An interesting ceremony took place last week at the city electricity works, Bolton-road, Bradford, when a presentation of a case of cutlery, subscribed for by the chief officials and staff, was made to Mr. F. Kershaw, who has recently left the service of the Corporation to take up a post as chief assistant to Mr. A. H. Gibbings, consulting electrical engineer, Bradford and London. Mr. C. B. Holdsworth, chief clerk in the electricity department, who was voted to the chair, spoke of the painstaking and courteous manner in which Mr. Kershaw had always carried out his duties, and of the good feeling that existed between him and the rest of the staff. Mr. S. T. Dalton (chief assistant engineer), Mr. R. A. Chattock (city electrical engineer), Mr. Jones, Mr. Goff, and other officials in kindly terms reiterated the sentiments expressed by the previous speakers.

Swansea.—At the last meeting of the Corporation Electric Lighting Committee it was urged that the Corporation should wire houses free and increase the cost. The Chairman said that an application for such powers would cause considerable delay. The only place where he could find it had been done was Worcester. There the resident engineer received applications and submitted estimates of fittings, which were then supplied by tender by private firms, the consumer either paying for them in a lump sum or by instalments. In the case of the National Free Wiring Company, they supplied the capital—that was the difference. It was eventually decided to recommend the Council not to proceed in the contract with the Free Wiring Company, but to carry out the work itself on similar lines, and the surveyor was instructed to prepare an estimate of the necessary amount to be borrowed.

Hackney.—Considerable discussion took place at the last meeting of the Vestry on the recommendation of the Electric Lighting Committee to receive and open tenders for condensing plant, cooling apparatus, pipework and valves, feed-pump, switchboard and boosters, meters, travelling crane, and workshop equipment. Mr. Richmond moved that the opening of these tenders be deferred six months. He defied the committee to complete the buildings or the chimney stack in less than 12 months, and this plant would not be wanted till then. They had paid a lot of commission already for work put on order, which would not be delivered for 12 months. Therefore any sensible or discreet business man would adjourn the acceptance of these tenders. At the present time the cost of every metal was at the apex; prices could not be higher. Therefore by accepting these tenders now they would be throwing ratepayers' money away. The amendment was rejected, and the committee's report carried, the tenders being initialled by the chairman, and referred to the Electric Lighting Committee and the engineer to consider and report upon.

Blackhill.—Mr. Thomas Trotter, of Blackhill, in the *Consett Guardian* gives details of his proposal for the working of an electric light, refuse destructor, and tramway scheme. He estimates that with fares 60 per cent. below those of the railway companies for the same distance, two cars at 2d. per passenger (only two are counted as working, one being spare in case of a breakdown), and making 51 journeys per diem, would earn on an average 1s. 4d. per journey operating 6·5 days per week. This would total to £2,298. 8s. per annum. To this he adds the assumed gas account saving of £500, and thus £2 798. 8s. would be obtained from the combined tramway and lighting scheme. The waters of the Derwent are to be utilised, and the expenditure he estimates as follows: one waterwheel, £250; dam construction, £350; two 30-kw. dynamos at £110, £220; storage batteries, £120; three cars at £350 each, £1,050; poles and trolley wire erected, £1,250; power-house, £220; car-shed, repair shop, and office, £230; rails and track making, £7,500; cables, etc., £420; lamps and sundries, £390; legal expenses at 5 per cent., £600—total, £12,600. Working expenditure per annum: one commercial manager, salary, £104; one electrical engineer, and one mechanic at 38s. per week, £197. 12s.; four car drivers at 6d. per hour, 8½ hours per day, 6½ days per week, £287 6s.; four conductors, same hours, at 3d. per hour, £143. 13s.; three machine minders at 6d. per hour, eight hours per day, seven days per week, £218. 8s.; one labourer at 6d. per hour, 48 per week, £62; interest on £12,600 at 3 per cent., £378; depreciation, 5 per cent. on capital, £630; sinking fund, £630; sundries, £125—total, £2,776. 7s. Therefore estimated income £2,798. 8s. minus £2 776. 7s. working expenditure leaves a balance of £22. 1s. per annum on the right side.

Lowestoft.—Application is to be made for a loan of £20,000 for electric lighting extensions on the basis of the following figures: A three-wire network to be laid in the following streets—London-road, town hall to park, Victoria arcade, London-road South, Pakefield road, Suffolk-road, Waveney-road, and Marina, £930; 39 arc lamps, posts, and cables (complete), £1,595; spare 3in. stoneware pipes (7,400 yards in all), £617; alterations necessary

Digitized by Google

for strengthening buildings, raft for engine-room, concrete flooring for boilers, deepening trench across harbour to satisfy Great Eastern Railway Company, £1,000; a three-wire distributing network to be laid in the following streets—Tonning-street (part), Bevan-street (part), Clapham-road (part), Gordon-road (part), Alexandra-road, Arnold-street (part), Old Nelson-street (part), Commercial-road (part), Duke's Head-street (part), Kirkley Cliff-road, Carlton-road, Beach-road, Grove-road, and Whapload-road (part), £1,875; two feeder cables and pilot wires from the generating station to Pakefield and Belle Vue Park respectively, £3,608; additional network to be laid as and when desired, £3,000; additional meters, cut outs, and house services, £2 000; one 250-kw. steam dynamo with accessories, together with boiler pipework and switch gear, etc. (complete), £4,175; legal and advertising expenses, printing, engineering fees, etc, £1,200—total, £20,000.

Salford.—The *Salford Reporter* has the following report on the local tenders recently accepted by the Corporation: "Alderman Shaw moved the acceptance of the tender of Messrs. W. T. Glover and Co., Limited, for supplying delivering, and laying the lighting cables, tramway feeders, and street-lighting accessories for the sum of £159,648. 12s. 8d. This was the lowest tender which conformed to the specification, and the cable would be subjected to the test mentioned in the specification before it was taken over. The consulting engineers would see the cables tested. Councillor Higson said there was one tender lower than Messrs. Glover's, but the reason it was not accepted was because they proposed to substitute tar in place of a bituminous compound. The British Insulated Wire Company, of Prescot were £650 below, but they did not conform to the specification. He congratulated the Council and Messrs. Glover that they had a firm within the boundaries of the borough capable of undertaking the work. Councillor Hailwood asked what the time limit was for the completion of the contract. Alderman Shaw: Before we are ready. The Mayor said he was pleased to find that there were local firms capable of doing the work they required. He had heard it said that directly they had some money to spend, they spent it a considerable distance from their own town. The local firms, such as Mather and Platt's, Galloways, and one or two others, could do their work, and it was pleasant to think that they were practically employing their own people. The resolution was carried."

Wrexham.—The Corporation of Wrexham will shortly be in a position to supply electricity for lighting and other purposes, and they have circulated a pamphlet for the use of intending consumers, from which we take that distributing cables are being laid in the following streets and roads, but the Corporation will consider requests for cables to be laid in other streets: High-street, Town-hill, Hope-street, York street, Chester-street, Regent-street, Bridge-street, Charles-street, Queen-street, and Henblas-street. Egerton-street is proposed to be included. The anonymous author of the pamphlet remarks, justly, that in the case of churches, chapels, or other buildings where large numbers of people congregate, it is well known that, with other artificial forms of lighting, unless ample ventilation is obtained, the building soon becomes unbearably hot and stuffy, and the atmosphere impure. With electric lighting the advantages are very apparent, and instead of a hot stifling atmosphere it is pleasant and cool. We give the concluding remark, entitled "Municipal Control," in full: "The Corporation incur a large expenditure in order to supply electricity in the borough for lighting, power, and other purposes, and if the ratepayers largely support this scheme, by taking a supply of electricity, the cost of generating can be so reduced that the consumers may expect to reap a substantial benefit therefrom. The profits made by the Corporation on the undertaking will not, as in the case of a company, be distributed in dividends, but will go towards cheapening the cost of supply, and indirectly diminish the rates. If those ratepayers of the borough who are in a position to avail themselves of a supply of electricity will give the scheme their liberal support, its success, from a commercial and financial point of view, will doubtless be assured."

Telephony in Mid-Wales.—Colonel Pryce Jones, M.P., who takes a keen interest in the proposal to extend the facilities for telephonic communication to the principal towns of Montgomeryshire and to Aberystwyth, has been in communication with the Postmaster-General on the subject, but from the letter given below it will be seen that he considers the demand for such facilities is not likely to be sufficient to justify the Post Office in making any move in that direction. Colonel Pryce-Jones does not propose to let the project drop, and he proposes to ascertain the minimum number of subscribers requisite to justify the extension of the system at any rate to Newtown. The following is the letter of the Postmaster-General: "General Post Office, London, Sept. 10, 1900 Dear Colonel Pryce-Jones,—I have had local enquiry made regarding your proposal that the Post Office telephone system should be extended to Newtown, Welshpool, Aberystwyth, and other towns in Mid-Wales, and, judging from the reports which have been received, I fear that there is little probability that sufficient support would be forthcoming from any of the towns or districts named in your letters to justify the expenditure that would be involved. At Newtown there appear to be only seven firms besides your own who are at all likely to avail themselves of telephonic communication, and even they, it is feared, would not take advantage of the facilities to any great extent, as they do not at present make much use of the public telegraphs. As regards the other parts of the district the prospects seem even less hopeful, as the great majority of the people, being engaged in agricultural pursuits, would have little occasion to use the system. I am sorry not to be able to send a more favourable reply, and I shall be happy to consider any local representations showing that adequate public support would be given to any extension of the trunk telephone system, such as you say in your last letter are likely to be forthcoming.—Truly yours, Londonderry.—Colonel Pryce-Jones, M.P."

Batley.—The plans for the electricity works to be erected off Field-lane, according to the *Batley News*, comprise a boiler-house, 61ft. by 64ft.; engine-house, 64ft. by 31ft.; condenser-house, 18ft. by 17½ft; and accumulator-house, 24ft. by 33½ft., with offices, stores, lavatories, etc. The chimney will be 6ft. in diameter and 150ft. high. The generating plant for the supply of power to the tramways, and for public street and private lighting, will consist of three Lancashire boilers, each 30ft. long by 7ft. 6in. in diameter, equipped with mechanical stokers, electrically driven, and three triple-expansion engines, each rated at 250 h.p., but capable of running for short periods at 300 h.p. These engines will be of the high-speed enclosed type, running at 400 revolutions per minute. The dynamos will be directly coupled to the engines, and will each have an output of 150 kw., and an emergency output of 180 kw. each. The machines will be so arranged that they may be used for either lighting or traction purposes. In the former case they will generate current at a pressure of 440 volts, and in the latter at 525 volts. The exhaust steam from the engines will be condensed by a large jet condenser, the pump for which will be steam driven. An economiser will be provided for heating the feed water for the boilers. The feed pumps for the boilers will be electrically driven, and an injector will be installed as a stand-by. The lighting of the town will be done on the three-wire system, the supply to consumers being at 220 volts. For purposes of balancing the load on each side of the system, a "balancing" machine, consisting of two 10-kw. dynamos, coupled together, and mounted on one bed-plate, will be used. A set of 252 accumulators of 400 ampere-hours capacity is being provided, the cells being charged by means of a special motor generator. A separate switchboard will be provided for both the lighting and traction systems. A travelling crane of 15 tons capacity will be arranged to run the whole length of the engine-room to afford facility for handling the plant. The feeder cables will be laid in cast-iron pipes, and the distributing cables in stoneware casings. The principal streets will be lighted by 20 arc lamps of 2,000 c.p. each. The trams will be run on the overhead (trolley wire) system. Messrs. Lacey Clirehugh, and Sillar are the consulting engineers

HAMPSTEAD ELECTRICITY ACCOUNTS.

The following is the report of Mr. A. P. Johnson, clerk to the Vestry of St. John, Hampstead, to the Lighting Committee on the working of the electricity department of the Vestry for the 12 months ended March 25, 1900:

It is again my pleasant duty to congratulate the Vestry and the ratepayers of the borough upon the result of a commercial enterprise of such unqualified success. For during the past year the undertaking has continued to steadily expand, with the result that larger profits have been secured and the price of the current supplied to consumers substantially reduced. This statement of loans requires little comment. It will be noted that only one loan—viz, £2,560 to meet the expenditure on the West End-lane arc lighting scheme—has been negotiated during the year. Still, this by no means represents the capital expended during that period, as by reference being made to the capital account it will appear that there is a balance of over £30,000 due to the treasurer. To in part meet this adverse balance, the Vestry have applied to the London County Council for the necessary sanction to raise a loan of £97,178. Negotiations for this loan are still pending. It will be remembered that this sum of £97,178 is principally to meet the capital outlay on the building and equipment of the large additions now being made to the present station, a small part of this amount being allocated to meet the annual increase of expenditure on mains, transformers, meters, etc. As foreshadowed in my last report, the total amount of loans repaid during the year has considerably increased, in fact, more than doubled that of the previous year—viz., £2,896 against £1 197. Of necessity, the net profits of the year have suffered thereby, yet the fact that the capital is being so steadily repaid is one of the distinctly favourable features of the year's trading. The question, however, which is now exercising the minds of many members of your committee is: "Is the capital being repaid fast enough, having regard to the rapid deterioration of the plant of an electric lighting station?" It would appear that the only safe course to pursue is to undertake the formation of a depreciation fund. Attention is directed to the fact that the last loan negotiated (referred to above) carries interest at 3¼ per cent., whereas the interest on the three previous loans was 3 per cent. The present condition of the money market points to a still higher rate of interest having to be paid on loans raised in the near future. It will be seen that the total capital outlay has reached the sum of £162,212—an increase during the year of £36,802. Building and machinery account for a large portion of this increase—viz., £11,436 and £10,952 respectively, or a total of £22,388. It is only fair to point out that of this latter sum £11,820 has been so far unremunerative, as this sum represents the amount expended, to the date of closing the accounts, upon the enlargement of the station. Mains, transformers, meters, etc., account for the remaining increase of £14,414. Of this sum the West End light

Digitized by Google

ing scheme made up £2,185, and the remainder is the usual yearly outlay incurred to meet the continued growth of the undertaking. It will be noticed that the sum of £1,160 again appears in this account as the value of the lands belonging to the Vestry appropriated for the purposes of the station. This sum is a purely nominal one, and by no means represents the true state of affairs. Your committee decided that the only proper course to pursue was to purchase the stoneyard outright, and to debit the undertaking with the fair market value of the site thus appropriated. By agreement between yourselves and the Works Committee this value has been fixed at £12,500. The consent of the Local Government Board is now being sought to carry out this equitable transfer. In the event of this arrangement being ratified, the capital account next year will be swelled by that amount. Two transfers from the revenue account to this account have been made during the year. The Vestry adopted the suggestion which I ventured to put forward in my last report—viz., of transferring the sum of £873, that being the amount disallowed by the London County Council on the loan transactions up to date, from the revenue account. In addition, the Vestry resolved to defray out of revenue the sum of £218 for arc lighting expenditure, for which sum a loan had been sanctioned. The increase in the capital expenditure for each period since the commencement is shown by the following figures:

		Increase.
15 months to Christmas, 1895	£56,522	—
15 months to Lady Day, 1897	83,331	£26,809
12 months to Lady Day, 1898	100,177	16,846
12 months to Lady Day, 1899	125,410	25 233
12 months to Lady Day, 1900	162 212	36 802

The working expenses, revenue, and gross profits are disclosed by the revenue account. Taking the expenditure first into consideration, the total working costs amount to £14,336, as against £11,363 last year—an increase of 26 per cent. It will be noted at once that the item "coal," amounting to £7,357, is more than half the total expenditure. This item shows an increase of £2 226, or nearly 50 per cent. over that of the previous year. Unfortunately, the increased output of the station cannot be made accountable for the whole of this heavy expenditure. It will be found that the increased price of coal is the main factor, and one that must still more seriously affect the economical working of the station in the future. The amount expended on repairs and maintenance is £678, as compared with £1,446 the previous year. It will be within the recollection of your committee that during 1898-9 exceptionally heavy outlays had to be made on these items, as fully detailed in my report for that year; fortunately, during the past year it has to a great extent been found unnecessary to incur any such heavy outlay. As a set-off to this, however, the distribution expenses have reached £674, as against £187 last year. The chief cause of this large increase is attributable to mains. This is an expenditure which must of necessity increase the older and larger the undertaking becomes. The increase in expenditure on repairs and renewals of public lamps is accounted for by the larger number of lamps erected and in lighting in the borough. Only one other item calls for comment—viz., discounts. Last year this amounted to £611, and this year to £8. 7s. 10d. This decrease is due to the introduction of the demand indicator, which directly extinguishes this item, although indirectly a much larger discount is, as a matter of fact, allowed to "paying" consumers under that system. Turning to the revenue side, the total receipts amount to £30,661, an increase of £6,283, or 26 per cent. as compared with the previous year. This can fairly be considered satisfactory, considering the new system of charge, coupled with the decrease in the revenue derived from public lighting. The average revenue per 8 c.p. lamp connected works out to 6s. 2d., as against 6s. 4d. the previous year. The comparison between the last two years as to the revenue derived from private and public lighting, taking into account discounts, is as follows: for 1899-1900 private lighting, £27,767; 1898-1899, £21,010—increase, £6,757. For 1899-1900 public lighting, £1,734; 1899-1899, £1,923—decrease, £189. The decrease thus shown in the public lighting is entirely due to the altered system of charge for the current supplied to the arc lamps. Formerly the charge was 6d. per unit with discounts, now the charge is fixed at £28 per annum per arc lamp, this charge representing the actual cost of supplying the current, together with renewals, etc. The result of this change has brought about a decrease in the revenue, notwithstanding the increase in the number of lamps in lighting. It is obvious, therefore, that formerly a considerable profit was secured under this head—this profit has, however, now ceased to exist. It may be remarked, *en passant*, that during the year the price to private consumers has again been largely reduced—the largest reduction so far made—namely, 6d. per unit for the first hour, and 2½d. afterwards, against the previous charge of 6d. for the first two hours and 2½d. afterwards. I here append the usual table showing the expenditure and income under their various heads (see Table A).

I cull the following figures from a report of the engineer presented to your committee, as being of interest: Lamps (8 c.p.)—1899, 82 672; 1900, 104,579; increase, 21,907. Consumers—1899, 1,268; 1900, 1,671; increase, 403. Weekly outputs in units: Highest winter load—1899, 43,027; 1900, 63,441; increase, 20,414. Lowest summer load—1899, 11,181; 1900, 14,633; increase, 3,452. A severe check was given to the number of consumers connected during the year owing to the Vestry having to refrain from taking new customers. This was unavoidable through lack of power at the station. Sir William Preece, the expert called in by the Vestry at the outset, reported in 1891 as follows: "If the experience of other localities is any guide, we may reasonably hope

TABLE A.

* In this year an additional amount of £68. 13s. 6d. was written off for preliminary capital expenses.

that in Hampstead we shall ultimately supply and fix about 24,000 16-c.p. lamps." This statement was, at the time, thought by many to be extremely optimistic. It will be gathered from the above figures that at Lady Day, 1900, the number of 16-c.p. lamps fixed was equivalent to 52,290! From the net revenue account it will be gathered that repayment of principal of loans, with interest, absorbed no less than £6,619 out of the gross profits of £16,325, while interest on bank overdraft (£348), and bad debts and allowances (£81) still further reduce the figures to £9,277, which, however, are increased again by the interest on stock investment (£80) to £9 357. As formerly, I would point out that, assuming the Vestry to be a private company, and the principal repaid to be equivalent to a contribution to a depreciation fund, the shareholders' dividend (assuming again that the whole of the remaining profits were appropriated for this purpose) would be 8·23 per cent. I give the "dividends" of previous years by way of comparison, it being necessary, however, to again point out that the decrease last year is brought about by the reduction in the price of the current: 1896-7, 5·59 per cent.; 1897-8, 7·0 per cent.; 1898-9, 9·5 per cent.; 1899-1900, 8·23 per cent. The following table gives the gross and net profits since the commencement of supply:

Gross profit.		Interest and principal of loans.	Interest on overdrafts, less credits.	Bad debts.	Net profit.
	£	£	£	£	£
To Christmas, 1895 (loss)	1,002	1,498	416	—	2,916 (loss)
Lady Day, 1897	5,258	2,288	1,066	4	1,900
" 1898	8,081	2 917	1251	8	3,905
" 1899	13,015	4,168	493	14	8,340
" 1900	16,325	6,619	268	81	9,357
	41 677	17,490	3,494	107	20,586

The total net profit, therefore, since the commencement of the supply is £20,586. Of this sum, £69 was allocated to write off th

Digitized by Google

preliminary expenses in 1896-7, while during the past year the deficit of £873, disallowed by the Council from the Vestry's applications for sanctions for loans, and the item of £218 in respect of arc lighting capital expenditure, for which a loan had been sanctioned, have both been defrayed out of revenue account, thereby still further reducing the surplus to £19,426. Of this surplus, it will be remembered that the Vestry have already invested £6,000 in London County 2½ per cent. consolidated stock as the first instalment of the reserve fund. Acting on the resolution of the Vestry—viz., that so far as the profits will allow, the reserve fund shall be kept up to 10 per cent. of the total capital outlay, in accordance with the terms of the provisional order—your committee have, on the presentation of these accounts, invested a further sum of £10,221 in the same stock. Thus there is at present standing to the credit of the reserve fund £16,221, an amount equal to 10 per cent. of the total capital outlay to Lady Day last. With regard to the balance—viz., £3,205—this has by the advice of your committee been placed to the formation of a depreciation fund, an amount equivalent to nearly 2 per cent. of the total capital. To show the allocation of the profits at a glance I append the following:

Total net profits as per above statement	£20,586	Written off for preliminary expenses, 1896-7	£69
		Loan deficit	873
		Transferred to cover capital expenditure, arc lighting	218
		Reserve fund.....	16,221
		Depreciation fund	3,205
	£20,586		£20,586

As regards the reserve and depreciation funds, I believe I am correct in stating that no other municipal undertaking in London of a like nature stands in so favourable a position as does that of the Hampstead Vestry. The wisdom of the Vestry in so dealing with the profits is unquestionable, for it must be understood (1) that the whole of the loans are borrowed for a period of 42 years; (2) that renewals during that period cannot be met by further loans; (3) that taking into account the high and continuous pressure at which the station is run, very heavy renewals of plant, etc., will have to be made from time to time; (4) that constant changes and improvements take place in the electrical world necessitating the replacement from time to time of antiquated plant by new and improved machinery, etc.; and (5) that in case of sudden and unforeseen accident or calamity happening at the station or elsewhere there is no fund to fall back upon save that of the rates. It is the primary wish of your committee to first place the undertaking in such a sound financial position that when in the future contributions can be made to the rates, such contributions shall be both uniform and sustained. The balance-sheet calls for no comment. The assets, as far as the consumers' accounts are concerned, are now almost wholly realised, and the liabilities entirely discharged. The engineer's statement as to the number of units generated, etc., is attached to the accounts as usual.

16049. Improvements in electric commutator bars. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (William Le R. Emmet, United States.) (Complete specification.)

16050. Improvements in controlling high-potential electric circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edward W. Rice, junior, United States). (Complete specification.)

16051. Improvements in systems of electrical distribution The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

16052. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

16064. A new or improved apparatus for automatically charging accumulators. Béla Klein, 55, Chancery-lane, London.

16081. A device for putting into and cutting out of circuit liquid rheostats operated by means of compressed air. Coleman de Kandó, 18, Buckingham street, Strand, London. (Complete specification.)

16082. Combined reversing switch and automatic maximum current interrupter for multiphase reversed current motors. Coleman de Kandó, 18, Buckingham-street, Strand, London. (Complete specification.)

SEPTEMBER 11.

16094. Walsh's connection rope to table attachment for use in the drawing in of electrical cables through iron, earthenware, or other conduits. Edward Walsh, 28, Newhall-street, Dudley.

16127. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

16128. Improvements in compounding electric alternators. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edwin W. Rice, junior, United States.) (Complete specification.)

16129. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

16130. Improvements in high-potential electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edward M. Hewlett and William Le R. Emmet, United States.) (Complete specification).

16144. Improvements in apparatus or means for varying the speed of electromotors. George Jackson Churchward and Francis Loder Waite, "Fairholm," Swindon.

16146. Process of making metallic duplicate phonograph records. Thomas Alva Edison, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16147. Improvements in electrically-propelled motor vehicles. Thomas Jefferson Ryan, 18, Buckingham-street, Strand, London. (Complete specification.)

16148. Improvements in electrically-propelled motor vehicles. Thomas Jefferson Ryan, 18, Buckingham-street, Strand, London. (Complete specification.)

16159. Improvements in and relating to lifting magnets. Eugene Bradley Clark, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16164. Improvements in electrical measuring instruments. Arthur Cecil Heap, 28, New Bridge-street, London.

SEPTEMBER 12.

16225. Improvements in measuring electrical energy and in apparatus therefor. Rankin Kennedy, 89, Gathorne-terrace, Leeds.

16226. Improvements in or relating to machinery or apparatus for covering electric cables, wires, and other cores. Isaac Lovell Berridge and Benjamin Kerr, 111, Hatton-garden, London.

SEPTEMBER 13.

16289. Improvements in induction coils or transformers. Herbert Watson Sullivan, 19, Great Winchester-street, London.

16290. Improvements in and connected with electric circuits for the transmission of energy by variable currents. George Ashley Campbell, 55, Chancery-lane, London. (Complete specification.)

16291. An electromagnetic regulator of the admission valves of gas or oil motors. Charles Denton Abel, Birkbeck Bank chambers, Southampton-buildings, Chancery-lane, London. (La Société Anonyme des Anciens Etablissements Panhard et Levassor, France.)

16293. Improvements in electric furnaces. John Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery lane, London. (La Société Electro-Metallurgique Française, France.)

16299. Improved construction of electric switch. Eduard Schulz, 166, Fleet-street, London.

16308. Improvements in switchboards applicable for electric call apparatus. Charles Shore and Charles Heap, 6, Bank street, Manchester.

SEPTEMBER 14.

16329. Improvements in or connected with electrical switches. Samuel Simpson Berry, Market-street, Huddersfield.

16357. Improvements in underground electric railway systems. John Denis O'Brien, 23, Coleman-street, London. (Charles Alexander Balph, United States.)

16375. Improvements in accumulator boxes. Henry Herbert Hill and William Frederick Hill, 4, South-street, Finsbury, London.

16389. Improved apparatus for trimming commutators. John Phillips, 37, Chancery-lane, London.

16395. Improvements in electric locomotives. John Smith Raworth, 46, Lincoln's-inn-fields, London.

16408. Improvements in the electrodes of electrochemical accumulators. Johannes von der Poppenburg, 160, Friedrichstrasse, Berlin, Germany. (Complete specification.)

SEPTEMBER 15.

16424. Improved automatic electrical cut-in and cut-out switches. Joseph Edmundson, Penny Bank-chambers, Halifax.

16466. Improvements in electro-hydraulic brakes. André Goldschmidt, 6, Lord-street, Liverpool.

Digitized by Google

16458. Improvements relating to the terminals of fuses, switches, and other electrical appliances. Archie George William Baxter, 18, Southampton-buildings, Chancery-lane, London.

16483. Improvements in portable electric batteries. Manes Ephraim Fuld, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Oct. 6.

1899.

14304. Application of electric motors for automobile vehicles. Thompson. (Cantono.)

18550. Armoured insulating conduits and the method of treating same. Brookes. (Lougee.)

18759. Disconnecting boxes for electric cables. Fowler and Reason Manufacturing Company, Limited.

19710. Wireless telegraphy. Brown.

20110. Electrical accumulators. Loppé, Morin, Martin, and Griner. (Date applied for under International Convention, April 1, 1899.)

20387. Manufacture of cement applicable for uniting porcelain, glass, metal, and other substances for the manufacture of electric glow lamps and for dental and other purposes. Sehr.

20438. Means for holding shades or globes for electric and other lights. Barker.

20793. Apparatus for regulating the speed of gas and like engines driving dynamo-electric machines. Richardson and Highton.

21082. Electric circuit breakers. Wright. (Date applied for under International Convention, March 23, 1899.)

21083. Controllers for electric motors. Davis and Wright. (Date applied for under International Convention, March 24, 1899.)

21670. Alternating electric current transformers. British Thomson-Houston Company, Limited. (Everest.)

21810. Electrical measuring instruments. Davis and Conrad. (Date applied for under International Convention, April 1, 1899.)

22164. Electromagnetic ignition device with revolving armatures for gas, petroleum, and similar motor engines. Thompson. (Sturm.)

22754. Alternating arc lamps. Davy.

23293. Trolley stands for electric railways. British Thomson-Houston Company, Limited, and Samuelson.

24437. Coin-controlled mechanisms for use in connection with prepayment electric meters or the like. British Thomson-Houston Company, Limited. (Cox.)

24740. Electric switches. Ely.

25701. Controlling apparatus for electric motors. Steven and Haigh.

1900.

7133. Incandescence electric lamps. Lake. (Washburn and Tinkham.)

12152. Method of increasing the capacity of lead secondary batteries in practical use. Heim.

NOTES.

"Science Abstracts."—We have received the September volume of *Science Abstracts*. The volume contains, as it usually does, a large number of abstracts of a very useful and interesting nature dealing with general physics, light, heat, sound, electricity, steam plant, telegraphy and telephony, etc.

National Telephone Company.—We note that the head offices of the National Telephone Company have been removed to Telephone House on the Victoria-embankment. The erection of these fine offices has occupied a considerable time, and it must be admitted that this building helps considerably to improve the appearance of the Blackfriars end of the Embankment.

Central Technical College.—The third annual dinner of the Association of Old Students of the Central Technical College is to be held on Tuesday, Oct. 2, at the Restaurant Frascati, Oxford-street. We are asked to state that old students can obtain further particulars from the hon. secretary, Mr. M. Solomon, 12, Edith-road, West Kensington, W., to whom applications for tickets should be made.

Poona College of Science.—We note that Mr. H. M. Page has been appointed to be professor of chemistry and geology, and to act as professor of physics and electrical engineering at the Poona College of Science. It would seem to us that Mr. H. M. Page's duties in his new positions will be too many to allow of the proper fulfilment of his duties in either of the departments, and we think that the post is one which should have the attention of two professors.

The Metallurgical Congress.—This is a year of congresses, and one is not surprised to find that a metallurgical congress has just been held at Paris. At this congress on Saturday the Swiss representative read a report on the situation of unionist metal workers. It was subsequently decided to hold a congress every five years. The congress also approved a proposal made by the British representatives in favour of a certain number of workmen belonging to the federation being sent from one country to another.

The Central London Railway.—After a very considerable period of waiting, the passenger by the twopenny tube who wishes to alight at Bond-street Station may now do so. The station was opened to the public on Monday last, and appears to be quite as popular as the other stations in Oxford-street. The station has during the past month or two had a rather ghostly appearance, owing to the use only of the incandescent electric lamps, which, with the white walls of the station, had a rather depressing effect. This is, however, now all changed, and the bright arc lamp sheds its rays in London's last new station.

"The Masonic Illustrated."—We have received a copy of the first number of the *Masonic Illustrated*, which, as its name implies, deals entirely with news concerning the fraternity of Freemasons. The paper is to be issued in monthly parts, and will, we presume, chronicle all the events, meetings, etc., which take place in the community which it chooses to represent. The journal is plentifully illustrated with portraits of various Masonic officials, as well as some views of the interior of the Freemasons' Hall in Great Queen-street, to which has recently been added a new wing. The usual first-number presentation plate is issued, the subject naturally being the Grand Master of the Order, the Prince of Wales. The editor in his leader speaks in a very optimistic way as to the future of his magazine, and we think, judging by the present issue, that to some extent this is justified.

Motor Mail-Vans.—Postal motors of various kinds have been tried from time to time in several large towns in different countries. The last one to take up the question is Paris, in which city the Paris correspondent of the *Daily Telegraph* states that there will be running a motor postal service. Mr. Mougeot, who is well known in connection with the French Post Office, is said to be studying a plan for the utilisation of electrically-worked cars or voiturettes for the speedy distribution of letters and telegrams. The cars will have somewhat the appearance of the tradesman's distributing cycle, and will have four wheels. We hope that these new aids to the quick delivery of letters and telegrams may be a great success.

The New York "Electrical Review."—We note with interest that our contemporary, the New York *Electrical Review*, by reason of its great success and the consequent expansion of its business, has found itself compelled to remove its offices from the Times Building to more commodious premises at 13, Park-row. The office building to which our contemporary has removed has a certain distinction of its own, it being the highest building in the world used for office purposes. It has no less than 31 floors, and requires 900 h.p. for its 7,500 electric lights and 10 electric lifts. We must heartily congratulate the editor of the *Electrical Review* on the success to which the paper has been brought, and hope that this success may be even greater in the journal's new home.

Electromobiles.—In a recent article the New York *Sun* thinks that at present the automobile which is most in favour is the electrically-propelled vehicle. It, of course, enumerates the objections to the accumulator-propelled car—that it cannot go very far with one charge, that the batteries are heavy, etc.—but yet thinks that electricity where it can be used is the favourite. Gasolene motorcars are stated to be very objectionable, owing to the odour which they emit, and which for some minutes after they have passed makes the air smell like burnt oil. Steam is said to be popular for long-distance travelling, this being naturally so, as it is fairly cheap and does not smell badly. It is to be hoped, however, that in a few years' time improvements will be effected which will give the electromobile a much wider range, and stations at which the accumulators can be recharged will also be probably more common.

Penny-in-the-Slot Telephones.—We notice that it is reported in the daily Press that Mr. C. J. Bayard and Mr. Arthur Lamkin, two London electricians, have invented an ingenious arrangement for supplying telephone calls for a penny-in-the-slot. In this instrument, by dropping a penny into the slot, it is put into working order, and the central exchange can be called up. The whole thing is automatic, and if a user does not want to bother with pennies every time he calls anyone up he can have each call notched against him by a ratchet-wheel arrangement. The great feature of this machine is, however, that if one puts a penny in the slot, or has a call notched against one, and the person called up cannot be put in communication with the caller, the telephone operator can cancel the notch or make the instrument return the penny by switching in another current. The instrument would seem to threaten the existence of telephone rentals.

London United Tramways.—The London United Tramways Company, having obtained concessions as to electric tramways in Middlesex, is now apparently turning its attention to Surrey. Thus a letter was read from Mr.

Digitized by Google

Clifton Robinson at the meeting of the Richmond Town Council last week, stating that although the time was yet somewhat distant for lodging formal proposals, he thought it only an act of courtesy to give them early intimation of his company's intention to apply in the next session of Parliament for powers to construct additional extensions to the existing tramways in the Richmond district, and to connect and work the same as part of their comprehensive system of electric tramways in Middlesex. If the tramway company obtains the powers for which it is apparently going to ask, there will soon be existing from the West of London to the nearer towns and villages an electrical tramway service which cannot fail to be of immense value both to Londoners and those in the towns through which the tramways run.

Rapid Transit.—Mr. H. C. du Val, of the New York Central Street Railway, recently returned from Europe to America, and consequently has given his views on how the traffic is managed in Paris and in London. The Parisian electric railroad, which has only been in operation a few months, he does not seem to think much of, and says the way of managing in Paris would not suit America. His first objection is that the cars seat only 36 persons, and there is standing room for eight; so that 44 passengers are taken up, and the crowd waits for the next car, which is besieged until another 44 are on board, when the crowd has still another wait. This does seem rather a bad plan, and Mr. du Val thinks that if the French officials had to handle a six o'clock crowd at Brooklyn Bridge, they would resign within 24 hours or end up in a madhouse. He does not say very much as to London, but remarks that there is the same wait as in Paris. We would, however, point out that there is generally room on the electric railways in London to take the waiting passengers, and the waits are not very long.

Damaging Electric Lamps.—We noted some time ago the case of a boy who was fined for throwing stones at telephone wires and insulators. A variation of this amusement is reported from Bootle, where the boys turn their attention to damaging the arc lamps in the town. The amusement consisted in the interference with the switch gear inside the lamp columns. The boys got a piece of wire and inserted it in the keyhole in the lamp column, and this in some way caused a short-circuit, which burnt the mechanism and damaged the enclosing box. The actual damage done to a particular lamp was about fifty shillings' worth, but the total damage during the week was estimated at £10. Mr. Wright, the electrical engineer, said he thought the boys did it to get a little shock, but very serious damage might result. In reply to the Bench, Mr. Wright said the lamps were similar to those in other towns, but the Corporation were about to take measures to prevent any recurrence of the mischief. The magistrates inflicted a fine of 1s. and costs upon each of the defendants, and ordered them to pay £1 damages. The parents were also warned to look after the boys, as if the latter came to the court again they would have to go to gaol.

Derailment Prevention.—Mr. W. T. Van Dorn has invented a device by which he claims high speeds can be obtained without derailing the cars. There is in the device no material variation from the ordinary standard road bed and rolling-stock. The only difference is that for about every fourth tie one somewhat longer is substituted on which to fasten the brackets for the support of the safety rails. These consist of ordinary T-rails turned upside down and bolted securely to the brackets, in this way somewhat increasing the stiffness of the road bed. The car axles, instead of terminating in a grease-box, are extended until they project out under the inverted safety rails, and are provided with a small anti-friction roller at their extremities, which travels along those rails. By having this roller insulated from the axle, and using a contact shoe on each side of the car, the safety rails may, it is stated, be insulated and used as the two sides of a trolley circuit and the cars run electrically, this being the most likely form of power for a high-speed service. The invention is no doubt one which is well worth considering, but it would appear to us that the inventor places too much confidence in anti-friction rollers, and we think that he would have great difficulty in overcoming the friction of which he speaks so lightly.

The Lakeside Tramways.—The inhabitants of the Lake District have recently been much disturbed, owing to the British Electric Traction Company having expressed its determination to seek powers to run an electric tramway in the district. The tramways are intended to compete with the coaches which run in the district, and which carry passengers to and from particular portions of the neighbourhood round the lakes. It is argued by the local people that electric tramways would entirely spoil the beauty of the place, and would prevent a large number of people who go there for quietness and solitude from patronising the district. To this the traction company reply that they quite appreciate that some people dislike, not only electrical tramways, but railways as well, and the few living in this secluded district may wish to maintain their seclusion. This, however, it is argued is not fair to visitors who go there, and who cannot afford to pay the excessively high coach fares which are charged. The company further state that there are numerous places of great natural beauty in America and in Europe in which electric tramways are used for communication, and the view in these districts is almost invariably that the greater the number of persons within whose reach the beauties of the district can be brought the better, and also that the introduction of electrical tramways appreciates the value of the property and the attractions of the district.

The Determination of Magnetic Force.—The committee of Section A of the British Association appointed to ascertain the most suitable method of determining the magnetic force on board ship, presented an interesting report to the section at the recent meeting at Bradford. The report was not read, but was briefly referred to by Dr. Lees. He pointed out that the great difficulty in determining the magnetic force on board ship was due to variations in strength of the magnets used. In fact, a number of the observations so obtained were rendered almost valueless by the assumption that the magnetic moment of the needle used in the experiments was constant. Up to the present the committee favoured the method of experimenting devised last year by Captain Creak, which was devised with the special object of getting over this defect. By this method two magnetic needles were used, and the experiments consisted in finding out the alteration in readings given by adding weights to the needles. In this way two determinations were obtained, and the third equation required to eliminate the magnetic strength of the two needles was made by observing the deflection caused by one needle on the other. In this way, with three observations one could be absolutely independent of the variations of the magnetic moment of either of the needles, and the true values of the magnetic force of the earth can then be accurately made on board ship.

Electric Heating.—Electric heating and cooking apparatus would seem to be more of a success in America than in England. It is true that Messrs. Crompton and Co. have a department which deals with this subject, but since the removal of the heating and cooking utensil works from Fulham to Chelmsford the matter would seem to have

Digitized by Google

taken somewhat of a back place in the firm's manufactures. At the last meeting of the company the shareholders were informed that the department was still carried on, and that it just paid its way, but that no very special efforts were being made to develop the industry. From America, however, we have received a catalogue of the Simplex Electrical Company, of Cambridge Port, Massachusetts, which deals entirely with electric heating. The process of manufacture, that of burying the resistance in enamel, which has been burned on to the article, would appear to be very similar to the Crompton method. The articles can be used both on alternating and direct currents, and they can be had for any standard voltage up to 220 volts. The articles include almost all domestic utensils which are used for boiling, grilling, frying, etc., and irons, sealing-wax pots, soldering irons, kettles, coffee-pots, foot-warmers, stoves, radiators, etc., are amongst a few of the numerous articles to which electricity is applied as a source of heat. With the development of electricity in Great Britain we may, however, look forward to the time when, instead of the ordinary coal fire or gas stove, our kettles will be boiled by simply turning a switch on or off as required.

An Overhead Line to France.—An idea, which does not strike one as being very practicable, was explained in a recent issue of the *Daily Mail*. An Italian with the high-sounding title of Comte Pompio Pieri claims to have invented a scheme by which the Channel Tunnel will be rendered needless, if ever it was otherwise. The inventor proposes to take passengers from Dover to Calais and *vice versâ* in a quarter of an hour without sea sickness, danger, and with a sea breeze thrown in. The electro-aerial railway which is to do all this is said by French engineers to be simplicity itself. Two strong cables, the upper one being charged with electricity and the lower one for steadying purposes, are to be upheld by some 50 captive balloons, and are to go from the highest points on the English and French coasts. Along these two cables cars capable of containing 10 persons, and supplied with electric motors, are to travel at lightning speed, this speed being accelerated by the sag in the wire. The car is to be built of aluminium and cork, and will float right side up if it happens to be precipitated into the sea. The wire will be supported at either end by large captive balloons, and small captive balloons will serve the purpose of lifts and land the people in the cars. The count thinks his scheme is daring but quite practicable, and states that we should have nothing to fear from France owing to its connection to us with this line, as the cables could be cut in five minutes, which, as our above-mentioned contemporary remarks, would be bad for those enjoying the sea breeze on it at the time.

Automobile Racing.—The automobile races which have taken place recently in America do not seem to have been so generally appreciated in that country as such races are in France. For instance, our contemporary, the *Electrical World* of New York, points them out as "a fine example of fruitless competition," and there is no doubt that this was the right way of looking at the particular races spoken of. They were open to all, like some horse-races, there being no limit to weight, size, etc. There was consequently a general scramble, out of which the machines with the biggest motors came first. The electrical machines, we notice, did well even under these absurd circumstances. Our contemporary protests against such foolish and reckless races, which, it thinks, will bring the automobile into disrepute, and will probably end in such restrictions being placed on motor driving as to prevent any enjoyment or use being derived from it. "Developing a speed of a mile per minute huddled up behind green goggles on a gasoline tank may be sport after the Gallic canons," thinks our contemporary, "but it will not go far or fast towards encouraging the general use of automobiles for practical purposes." The road races of the early summer were more to the point, as they brought out machines capable of fairly hard service and ample speed for ordinary uses. The faults of automobiles at present are not in the speed, but in weight, noise, smell, short radius of action, and general complication. For pleasure riding, a machine that can make 15 miles an hour if necessary, or run 40 or 50 miles without attention and with the reasonable certainty of getting home, is much more useful than a racer which may make 40 miles in an hour, and have to be left on the road to be sent home by rail.

A Submarine Arc Lamp.—It may be remembered that some time ago an arc lamp for submarine purposes was invented, but which failed for various reasons. We now learn from the *Electrical Review* of New York that the inventors did not despair of accomplishing their object, and after a considerable amount of investigation claim to have at last obtained an arc lamp suitable to submarine use. In this lamp no air-tubes are used, oxygen being fed to the lamp by a secret process. The diving outfit includes the lamp, portable waterproof cable, and switch for turning the light on and off. The lamp consists of an upper mechanism chamber, containing a solenoid and other mechanism. The lower chamber is enclosed in a glass globe, which is hermetically sealed by means of rubber gaskets to the upper chamber. Inside this lower chamber is placed an inner globe and carbons. The length of the lamp is 22in., and the metal parts are of gunmetal. The glass globes are constructed to withstand a pressure of 500lb., allowing a depth of 1,000ft. to be reached with safety. This is, of course, more than sufficient for all ordinary diving cases. The lamp is equipped with Holophane globes, these having a high diffusive quality, and avoiding the casting of sharp shadows by the framework of the lamp. The lamp is very compactly built, and can be used in very confined spaces. In the light of the enclosed arc lamp practice, we are not quite sure that it is the inclusion of oxygen which it is said is required in order to make this lamp a success, but think it might possibly be that some means should be provided to enable the gases to expand, and also those gases formed by combustion to escape. It is interesting, however, to note that the inventors, the Naval Electric Company, have succeeded in getting an arc lamp which will be of real use in submarine work.

Commutators.—The bursting of a commutator on a booster at the Plymouth electricity works reminds one that in designing commutators the mechanical details require careful construction. In the early days we remember two or three similar accidents in which a commutator burst, throwing sections of copper in all directions. More recently we have heard of large machines in which the mechanical details for securing the commutator sections in place have been defective. With these large commutators and high-speed engines the circumferential speed is very considerable, and the centrifugal force reaches a high value. One is not surprised, therefore, that steel of a high quality is entering into the construction of practically all commutator supports for large multipolar machines. Referring to the accident at Plymouth, we notice that a most circumstantial account has been published in the local papers, in which the engineer in charge of the station at the time covers himself with glory in giving exceedingly full details of what he did after the accident happened. The gentleman in question is lucky not to have been in the line of fire when the fragments were flying round,

Digitized by Google

but we do not think it does any good whatever to the undertaking to put accounts of such detail in the untechnical Press. Although serious damage might have been done, no personal injury was caused, and as soon as Mr. Rider arrived on the spot the tramway service was restarted. We therefore hold that the local papers should have been satisfied with the statement that there had been a slight mishap to one of the running machines, which would in no wise interfere with the running of the tramways, nor would it cost any considerable amount to repair. We do not quite go so far, however, as one borough engineer of our acquaintance, who, when the arc lighting of the public streets went out, assured his committeemen that he had cut them out in order to test the circuits. He did not state that the testing was a necessity owing to a bad breakdown in the insulation.

The Question of Brakes.—When commenting a few weeks ago on the report of the commission of the New York State, in which it was advised that more powerful brakes were required on most of the tramcars in that State, we alluded to the fact that the committee of enquiry, although appointed by the State, had not means to enforce any decision on the tramway companies. It will be remembered that a large number of trials were undertaken with electric brakes, from which good, useful conclusions were derived as to which of the various electric, compressed-air, and hand-power brakes were most effective. We now notice in our contemporary *Electricity*, of New York, that they interviewed the presidents of the Metropolitan Street Railway Company, and also of the Brooklyn Rapid Transit Company. Both of these gentlemen are apparently experts in avoiding a direct reply to a question, and the first, Mr. Vreeland, even questions the advantage of having powerful brakes. He asks who would care to ride in a car, the brakes of which would stop it within 30ft. or 40ft., and he appears to infer that once in a way the car not so equipped should be stopped by running into a brick wall or into other traffic. He, of course, has a word to say as to the advantage of using a couple of chains instead of one on a hand-power brake, which his company has done. President Rossiter, of the Brooklyn Rapid Transit Company, gave his views on the same general lines. His company were extremely interested in the trials made on behalf of the State, in order that they might be compared with similar trials which they themselves had undertaken. Of course his company were exceedingly anxious to adopt the best brake, and having hedged to that extent, one gathers from the remaining statements that he would neither accept the verdict of the committee as to which was the best brake, nor would he advise any extra expenditure on the brakes for his tramcars at the present time. In fact, neither of the gentlemen will take any advice from the committee, nor will they expend anything on improving their systems of braking in consequence of the report. We here therefore reiterate our point, that in such matters Government control, as exercised by the Board of Trade, is the best.

Water Power from the Rhone.—We notice in the August issue of the *Bulletin* of the Société des Ingénieurs Civils de France a description by Mr. M. F. Bonnefond of the water power available and of the schemes for utilising the same on the higher waters of the Rhone. The author states that from Pyrimont to Fort de l'Ecluse the Rhone falls rapidly through a series of gorges and waterfalls. Thus in a length of 12½ miles the total fall is no less than 210ft. Again, the Lake of Geneva acts as a reservoir to keep the flow in the river within limits, and the minimum amount of water passing down the river is said to be at least 5,250 cubic feet per second. From this the author works out that the minimum effective horse-power which can be obtained from the water in the driest months is 100,000 h.p., while for nine or ten months in the year one could depend on getting at least 200,000 h.p. Up to the present the only quantity used amounts to 10,000 h.p., which is obtained by an Anglo-Swiss company, but there are three schemes on foot organised by French companies, which only wait for the formal sanction of the authorities before commencing work. It is said that this consent is now exceedingly difficult to obtain quickly, and that whereas 30 years ago all the formalities could be completed within three months, it is now actually two years since the present French companies first applied for permission. The author then proceeds to describe these three schemes and the civil engineering works which will be necessary in carrying them out, but for these details our readers will do well to seek the volume above mentioned. The names of the schemes and their engineers will, however, be of interest. The first, which would have its works about 2½ miles from Bellegarde, would when completed be able to provide 25,000 h.p. even in the winter months, when the river is lowest. The engineer who is responsible for this scheme is Mr. Supéry, of Lyons, and it is being financed by Messrs. Planche et Cie. The next scheme takes its name from the Boucle du Rhone, and would develop 30,000 h.p. from a fall of about 90ft. The engineers for this scheme are Messrs. Gotteland and Garcia. The third scheme, called after the Pont de Grésin, is due to Messrs. Buffaud and Tavian, of Lyons. In this case the fall utilised is above Bellegarde, and here again 30,000 h.p. is expected to be obtained. The horse-power which will be developed at these three stations would be largely used for electro-chemical and electro-metallurgical purposes, but, of course, the electricity could also be transmitted to the various industrial centres within a range of from 75 to 100 miles. The author states that the various promoters think that £2 per horse-power hour per annum will repay for the cost of the works, and this will be about one-tenth of the cost of the horse-power per annum in the district when obtained from coal.

The Viagraph.—At the recent meeting in Bradford of the British Association, Mr. J. Brown read a communication on an instrument, called by him the viagraph, for testing and recording automatically the unevenness of the road surface. The subject is one which is of great interest to manufacturers of automobiles, and hence to those electrical engineers who are working on the problem of accumulator traction on ordinary road surfaces. Since the meeting we have had the opportunity of inspecting the instrument in London, and one cannot but be struck by the simplicity of the mechanism and by the ingenuity displayed by the designer in its construction. The viagraph consists of a sledge, the runners of which are straight edges about 16ft. long. In the middle, between the two runners, is a toothed wheel of from 3in. to 4in. in diameter, which always rests on the road surface. The revolution of this wheel is reduced by suitable gearing until it moves the drum carrying the recording paper. The reduction is such that ⅛in. of the motion of the paper represents 1ft. along the roadway. The vertical movement of the wheel which is carried on the lever is reproduced to scale by a pencil resting against the recording strip of paper. In this way a jagged diagram is produced, which gives one a good idea of the local unevennesses which occur on the road surface. In order, however, to give some indication of some of the vertical movements through which the wheel resting on the road surface is moved, an ingenious arrangement is added of the following nature: A cord from a point on the lever near the wheel axle is carried over guide pulleys to the driving wheel of a counting train. This driving wheel is provided

Digitized by Google

with a ratchet, so that it only drives in one direction, and moves back without altering the train in the other. In this way a record is obtained of the total vertical displacement in one direction only. The author gave as an example the record obtained in this way when on the Guildford road, on which the sum of the depth of the ruts is from 12ft. to 14ft. per mile. On the Prescot road, from Liverpool, the average of several readings gave 42ft. per mile, while on the Lisburn road, near Belfast, no less than 134ft. of rut per mile was recorded. The above figures suggest an interesting experiment as to the additional energy required to drive a vehicle over an uneven road. The actual energy wasted in the vertical vibration in the framework of an automobile, and also of its contents, is a subject which requires careful investigation. That this vertical vibration would waste a considerable amount of energy, is obvious from the great advantage given by pneumatic tyres over solid rubber tyres, as experienced by the cyclist. It was suggested in the discussion which followed Mr. Brown's paper that such experiments should be actually made. In this case, trials made with an automobile supported free from the ground, with brakes applied to the driving wheels, would be used as the datum line.

Radio-Telephony.—We notice in the *Revue Générale des Sciences* a description by Prof. A. Popoff, of Kronstadt, of some experiments in radio-telephony. He states that in May, 1899, he was experimenting with wireless telephony on two islands near Kronstadt, when suddenly the signals ceased to be received although transmitted. He then tried the effect of placing a telephone in the circuit of a radio-conductor and dry battery. He then found that the signals transmitted were perfectly audible in the telephone. On other trials he found that only weak currents would produce this effect. For experiments at long distances he used a glass tube in which were pasted small bands of platinum upon which rested steel filings mixed with crushed pearl. The tube was well dried and hermetically sealed. This radio-conductor, he found, was preferable to any other. The electric waves were found to successively increase and decrease the resistance of the radio-conductor. After reading an article by Hughes, the inventor of the microphone, which stated that a combination of the microphone and telephone might show the existence of electric radiations, the author tried several forms of microphones, but found the combination only good for more powerful currents. Last winter, Prof. Popoff states, an accident occurred to a war vessel in the Gulf of Finland, and to facilitate the work of saving the vessel, which was ice-bound, it was necessary to establish a system of wireless telegraphy between the island against which the injured vessel lay, the continent, and the ice-breaking vessel, "Ermack.' The professor was intrusted with this work. Sets of apparatus were placed on the island and at the village of Kotka. The first trials were made with a kite in order to determine the best position for the masts. When the masts were fixed, dispatches were easily sent and received. An ice-floe had broken adrift with 27 fishermen upon it, and a dispatch was sent to the ice-breaking ship in a few minutes. The dispatch was received perfectly, and the ship saved the fishermen, who were floating out at sea on the ice-floe. This immediate application of wireless telegraphy, he states, caused some sensation. The posts which were established included two telegraphists and an assistant electrician. The two stations were supplied with Ruhmkorff coils giving long sparks. The masts at Kotka and Hohland were about 50 yards high. Messages were regularly transmitted between the posts, and during the 84 days in which work was going on, 440 officia telegrams were exchanged. The longest dispatch contained 108 words, this being the Press message to the effect that the vessel was saved. The weather was very bad, heavy snow falling, but the messages were not interrupted. The author believes this to be the first regular service of wireless telegraphy. During the time the telegraphy was employed the temperature did not rise above 12deg. F., and went down as low as 20deg. The author thinks that, in view of the work done in this instance, the use of radio-telephony, being very simple, will become of great service in the future.

An Electric Automobile with Trolley.—Mr. J. W. G. Aldridge's paper on "An Automobile for Electric Street Traction," read before Section G of the British Association at Bradford, was remarkable for the inconsistency of certain of the opinions expressed. Mr. Aldridge is, however, to be congratulated on the use of the cinematograph for illustrating the flexibility of the system he advocates, although the instrument at the same time illustrated defects in certain respects. The system of electric traction in question is that developed in Paris, on the road to Vincennes, by Mr. Lombard Gerin. While up to the present we do not think the system is commercially feasible, every credit is due to the inventor for the ingenuity displayed by him. We have previously referred to this system, which consists of a motorcar running on the ordinary roads and fed from two trolley wires by the side of the road. Instead of the usual trolley for collecting the current, a flexible cord containing six conductors is used. This cord connects to a small carriage which runs on the two trolley wires, and which is driven by means of a synchronous three-phase motor, which is supplied with current from three slip rings on the motor on the car. The speed of the small motor on the trolley wires is made slightly more than is required to keep pace with the vehicle, so that the dragging on the wire is avoided. By means of a brake the advance can be restricted by the driver. The author explained that the jolting of omnibuses on the common roads was so terrible that they would have to be replaced, but he failed entirely to explain how he expected the electrically-driven 'bus to avoid the jolts which are due rather to the road surface than to the means of propulsion. The great objection to the system up to the present seems to us to be that the small motors running on the trolley wires will not be able to pass each other. Thus we were shown on the cinematograph the operation which had to be conducted when two of these electric automobiles met. It involved the change over of the conductor from one car to the other, and although the work was smartly done, the interval was much too long to be allowable on any important roads. We were told, however, that the inventor had succeeded in solving the question which has so long troubled the mind of the erratic engine driver of how two trains running on the same line towards each other can pass without destruction. The other alternative, of providing two trolley wires on both sides of the street, considerably nullifies the author's claim that the system is cheaper than the ordinary trolley. In the discussion which followed the paper, one or two of the speakers mistook the action of the motor on the trolley, thinking that it was a converter from direct current to three-phase current. Another suggestion was that the underside of the trolley motor, which with its wheels weighs about 40lb., should be provided with rubber springs, so as to reduce the damage done when the said motor falls on the heads of pedestrians passing underneath. The weight of the vehicles was stated by the author to be about three tons empty and five tons loaded, and at ordinary speeds on ordinary roads they required from 130lb. to 160lb. per ton-mile,

THE ELECTRIC LIGHTING OF THE CITY OF GLASGOW.

(Concluded from page 413.)

The engine-room presents some novel features; indeed, one's first impression on entering this portion of the station is that it is the electrical section of an international exhibition. There are dynamos from England, America, and Germany; engines of four different types from as many different makers in Scotland, England, and America. The plant first installed was set to work in a wooden shed built inside the main engine-house, it being imperative to get a supply of current for the winter of 1898-99, and all quarters of the civilised earth was searched with a view to obtaining the necessary plant. The smallest unit consists of a 200-h.p. set, comprising a Crompton bipolar dynamo of 125 kw. output coupled to a Mirrlees-Watson engine of 200 h.p. The combination runs at 380 revolutions per minute. Next in point of size comes another Mirrlees-Watson-Crompton set. The dynamo is of the usual bipolar type, having an output of 255 kw., and driven by two engines, duplicates of the one already mentioned. The two engines are coupled in line, and give a brake horse-power of 400 at 380 revolutions. They can easily be seen in Fig. 6, the set almost immediately below the crane hook. Recognition will be easy, as they have the doors of the crank chambers removed. The large unit beyond is an ordinary marine type three-crank triple-expansion engine, made by Messrs. Matthew Paul and Co., of Dumbarton. The indicated horse-power is 900, and it has its own condensing plant driven from the engine cross head in the orthodox marine fashion. It is the only unit in the station which drives its own condenser; the others have independent motor-driven condensing apparatus. This marine engine drives a 12-pole dynamo by the Schuckert Company at a speed of 120 revolutions per minute. One distinctive feature of the machine is its armature, which is smooth core—the only smooth-core machine in the station. Its output is 650 kw. The set at the extreme end of the engine-room consists of a Ball and Wood engine of 100 h.p., with two Walker dynamos, one on each end of the crankshaft; their output is 350 kw. each, and as the E.M.F. is 250 to 270 volts they are used as balancers on the three-wire system (500-550 volts between outers). It has an independent motor-driven condensing set, which will afterwards be described.

The more recent additions to the station plant consists of three units. Two are Belliss-Thomson-Houston sets, and one a Willans-Crompton set, and they can easily be recognised in the foreground of Fig. 6.

The Belliss engines consist of six-cylinder three-crank triple-expansion engines. The cylinders are one high pressure, two intermediate, and three low-pressure, the three latter being placed below the single high and the two intermediate cylinders. The slide valves are of the piston type, the high or intermediate and low pressure valves being on the same valve rod and operated by a single eccentric. Each engine is capable of giving 1,100 b.h.p. continuously when running at 230 revolutions per minute with steam at 180lb. (stop-valve pressure), or 1,500 h.p. for short periods. Coupled to each engine is a 12-pole British Thomson-Houston dynamo, having a rated output of 655 kw. at 500 to 550 volts, and over-compounded for a rise of pressure of 10 per cent. at full load (they are generally run as simple shunt machines). They are of standard B. T.-H. design, having all the usual features. There are as many sets of brushes as there are poles; each set consists of seven carbon brushes.

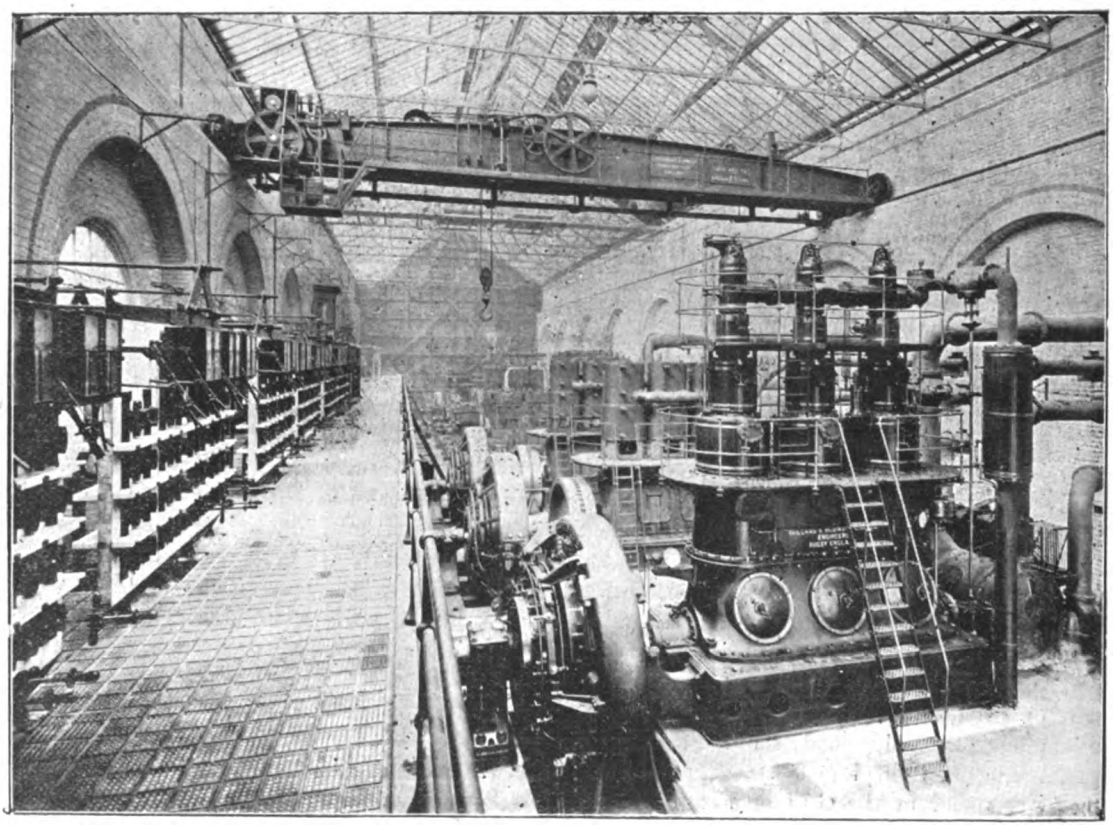

FIG. 6.—General View of Engine-Room, taken from Switchboard Gallery.

The Willans-Crompton set consists of a 1,200 i.h.p. to 1,500 i.h.p. Willans engine running at 230 revolutions per minute, coupled to a Crompton 12-pole dynamo. The generator has several features of interest. The field magnets are of the usual construction—laminated pole-pieces cast into a cast-iron yoke. The series winding is, however, outside the shunt and held clear of it by means of three insulated brackets. This permits a free circulation of air between the series and the shunt winding, with the result that the range of temperature, and consequent variation of the shunt resistance, is not so great as it would otherwise be. Each turn of the series winding is divided into four parallel strips to facilitate removal—an advantage when dealing with copper of such large cross-section. Another notable feature is that the combination has no flywheel. The only other unit in the station lacking the flywheel is the Ball and Wood-Walker combination. All the necessary flywheel effect is obtained from the armature, which is carried on a steel hub and bolted direct to the barring wheel of the engine. The armature spindle is, therefore, not subjected to the torsional strain which it would otherwise have to bear. The brushes are carbon, held in aluminium brush-holders. The station is yet only one-

Digitized by Google

third its ultimate size, and at the time of our visit foundations were being prepared to receive some important additions — viz., two Willans-Westinghouse sets — the engines being of 2,500 h.p., and duplicates of the Willans engine at the Paris Exhibition.

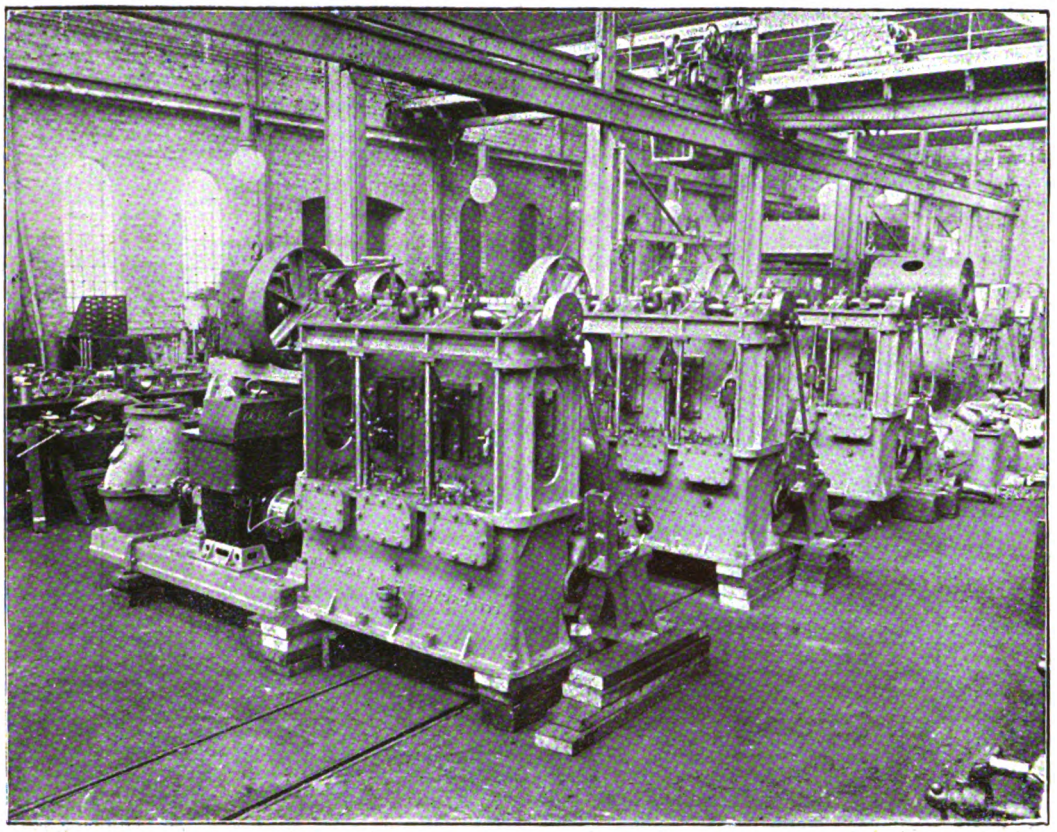

FIG. 7.—Electric Air Pumps of the Edwards type, driven by Allen Motors.

The elements of each consist of a surface condenser, which can be seen in Fig. 6 immediately below the separator of the Willans engine (the exhaust pipe from the engines is fitted so that the engine may exhaust either into the condenser or to the atmosphere), a three-throw Edwards air-pump, and a centrifugal circulating pump, each pump being driven by a separate electric motor. The shells of

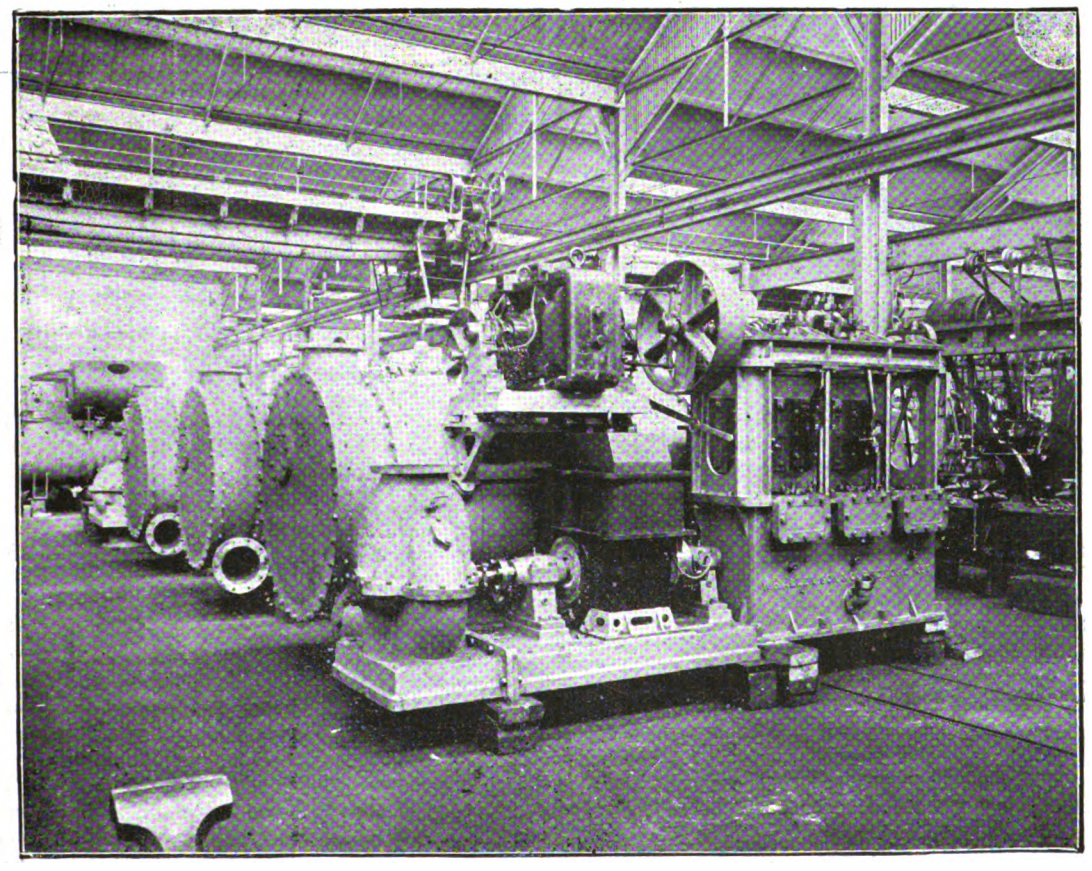

FIG. 7A.—Another View of the same Pump, with a Circulating Pump in Foreground.

Condensing Apparatus.—With the exception of the marine engine already described, which drives its own condenser, all the other units have separate motor-driven condensers, made by Messrs. W. H. Allen, Son, and Co., Limited, of Bedford. They are of the surface-condensing type, capable of dealing with 27,000lb. of steam per hour.

Digitized by Google

the condensers are of cast iron, cylindrical in form, fitted with branches for the exhaust and circulating water inlets and outlets, and air-pump suction. Each condenser has a cooling surface of 2,550 square feet, the tubes being of solid-drawn brass, fixed into rolled naval brass tube plates, by means of screwed ferrules and tape packing. These ferrules are provided with lips to prevent the tubes from slipping out of place, while allowing sufficient play for free

they can deal with 225 amperes, raising the pressure by 160 volts. There are two sets of balancers—one a bipolar set by the India Rubber, Gutta Percha, and Telegraph Works Company, capable of dealing with 250 amperes on either side of the system, and a four-pole set by Bruce Peebles capable of dealing with 500 amperes. The fields are excited differentially so as to reduce the amount of manipulation by hand.

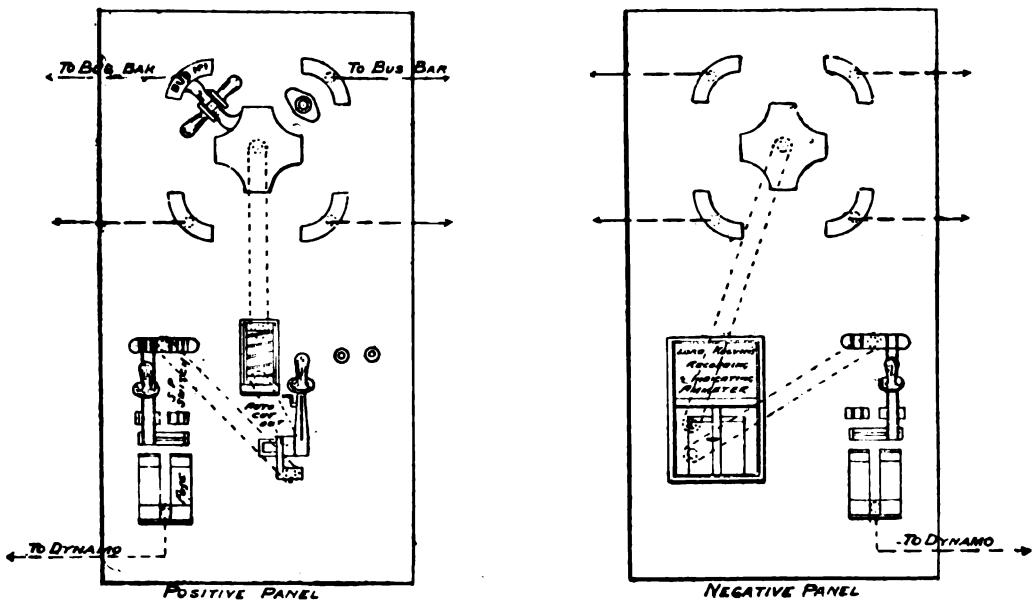

FIG. 8.—Generator Panels—Port Dundas Station.

expansion. The air-pumps are designed to run at 160 revolutions per minute, and are driven by an Allen motor. Each pump has three barrels 12in. diameter by 12in. stroke, of Edwards's well-known pattern. They are driven from an overhead crankshaft, as seen from the photograph, Fig. 7 (taken in Messrs. Allen's shops). The pump seen on the overhung crank on the right-hand side is a small water-pump for dealing with the hot-well water. The circulating pumps are of the "Conqueror" type, the suction

Accumulators.—These consist of 334 cells, made by the Tudor Company. They are divided into two batteries of 167 cells on either side of the three-wire system. One battery is located on each side of the tower, as seen in Fig. 4 (last week's issue). They are of the Tudor Company's type L B. 19, and have a capacity of 1,100 ampere-hours. Their normal rate of charge is 180 amperes, and normal discharge 150 amperes for 7⅓ hours. They may, however, be discharged at 330 amperes without damage.

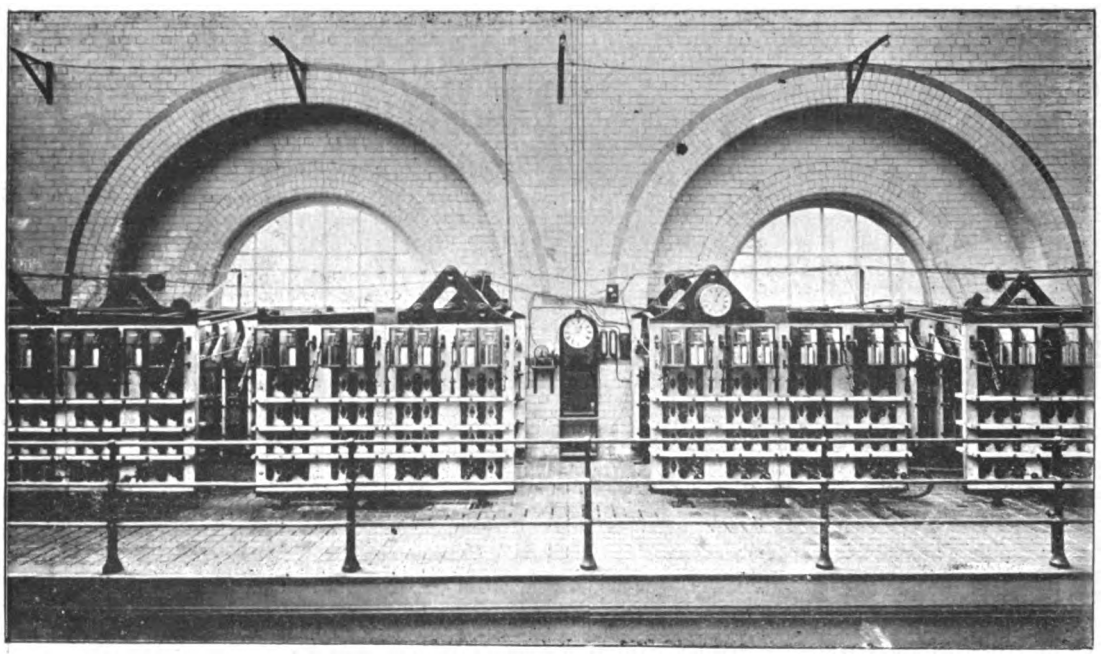

FIG. 9.—Front View of Feeder Panels on Gallery.

and discharge being 11in. in diameter. The pump spindle is directly coupled to the motor shaft, and when running at full speed takes about 75 amperes at 520 volts.

Balancing and Boosting-Sets.—Located in the middle of the station, between the old and new units, are the balancing and boosting machines. For charging the accumulators there are two sets of motor-driven boosters, by Messrs. Mavor and Coulson, Limited, Glasgow. They have field magnets of the Manchester type and drum armatures;

The regulating switches are arranged along the wall of the battery-room, and are worked by a sprocket wheel and chain from the dynamo floor of the engine-room, close to where the attendant manipulates the balancing sets.

Switch Gear.—This presents some features quite unique in central-station practice. Owing to the great output (there will be some 44,000 amperes to be dealt with at no very distant date), not a few departures from the recognised practice in central-station designs are noticeable. For

Digitized by Google

instance, the dynamos are not controlled from the main switchboard, their output being dealt with at smaller boards on the dynamo floor, the feeders only being controlled from the switchboard gallery above. The generator panels consist of a + and a − panel, one on either lead from the dynamo. Each generator has its own pair of panels immediately opposite it. The + board consists of a four-way combined plugging and switching device. This enables the dynamo to be plugged on to any of the four + 'bus bars, which run along the underside of the switchboard gallery for its entire length. Current as it comes from the dynamo passes through a switch to a duplex fuse, and then through an Andrews cut-out to the four-way switch already described. Some of these panels were made by Messrs. Jas. White, Glasgow, and some by Messrs. Cowans, Limited, Manchester. A diagram of those made by Messrs. White is shown in Fig. 8, from which the connections can easily be traced. Messrs. Cowans's panels were similar, though the relative position of the fuses are different, being in the centre of the board. The minimum cut-outs are set to take a back current of 350 amperes before dropping out; the reason being that should a short pull the engine up, and the battery try to motor the dynamo, the unit may have an opportunity to recover its load before cut out of the circuit. The current returning to the dynamo through the negative panel passes first through the four-way combined switching and plugging switch, seen on the right-hand panel of Fig. 8, then through a Kelvin combined recording and indicating ammeter reading to 2,000 amperes, thence through a duplex fuse and a switch to negative pole of dynamo. The equaliser switch of the machine—it will be remembered they are compound wound—is placed on the yoke of the dynamo field magnets. From the + dynamo panel connection is made to any one of four positive 'bus bars which run under the gallery. These consist of 22ft. lengths of copper strip coupled together at the ends by thin U-shaped strips, 4in. broad by ¼in. thick, these serving as expansion joints for the total length of 216ft. The 22ft. lengths consist of four bars, the bottom one being 4in. broad by 1in. thick, and three others 4in. wide by ¼in. thick, giving, when assembled, a total section of seven square inches. The strips are separated from each other by copper washers, and bound together by means of steel bolts, enabling more copper to be added. Should necessity arise for increased section, it may be increased to 14 square inches with ease. The construction of these bars in strips, separated by copper washers enables a very large section of copper to present an unusually large radiating surface to the atmosphere, hence the current density may be increased to a much greater extent than usual without undue rise of temperature. The bars, of which there are eight (four + and four −), are carried on porcelain insulators along the underside of the switchboard gallery, and connections are taken from them to the feeder panels above. Here Mr. Chamen's ingenuity has enabled him to solve many of the knotty problems which arise in the design of boards dealing with such large currents. Connections from the 'bus bars under the floor are taken to the short bars on the back of the feeder panels. These feeder panels are divided into sets, each set supplying eight feeders. Fig. 9 gives a front view of the feeder panels on the switchboard gallery. On each panel are grouped eight feeders, and the panels are arranged starting from the extreme right of Fig. 9: +, −, clock, +, −; two complete panels, one + and one − being seen on either side of the clock, and portions only of the other two. They are all in duplicate, positives and negatives being alike in

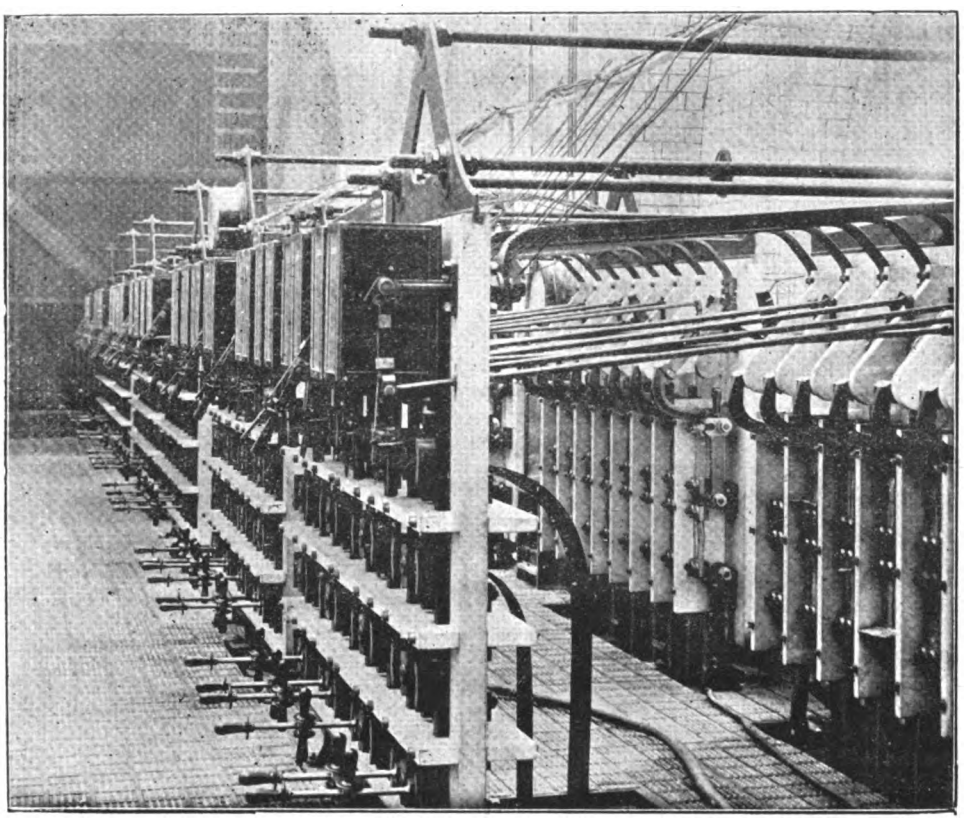

FIG. 10.—Side View of Switchboard.

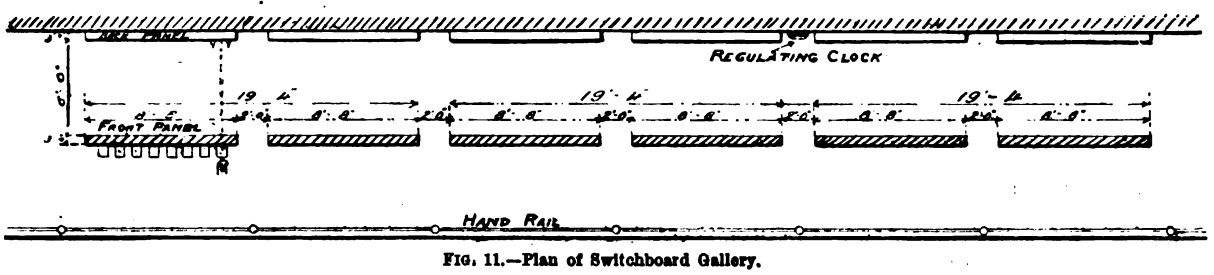

FIG. 11.—Plan of Switchboard Gallery.

Digitized by Google

all respects. They are constructed of marble slabs carried on an iron framework. The four horizontal bars seen across the lower portion of the board are marble slabs separating the four short bars, which are connected to the main 'bus bars below the floor. It is possible by means of the combined plugging and switching arrangement to plug any feeder on any one of the four main 'bus bars, and, therefore, run any dynamo on any pair of feeders should this become necessary. At the top of the board will be seen the measuring instruments, which consist of a Kelvin combined volt and ampere meter, indicating and at the

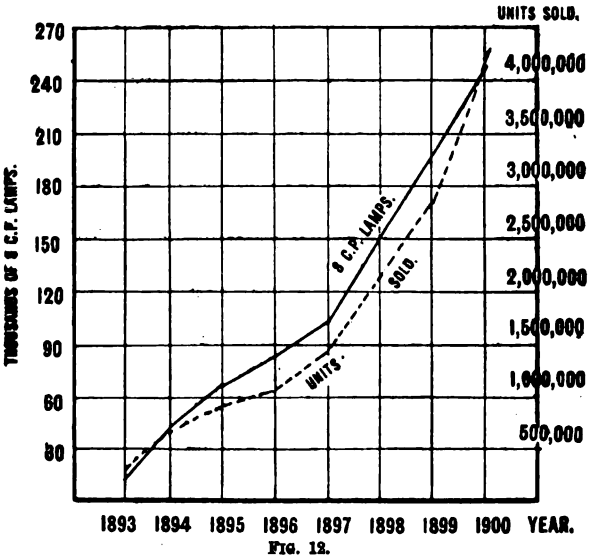

FIG. 12.

same time recording both the pressure and current on a sheet of paper. The attendant can thus see at a glance the pressure at the ends of the feeders (the voltmeters are calibrated for drop of pressure in the feeders), and the current, while a continuous record is kept. The clockwork mechanism operating the drum which carries the paper on which the record is made, is impelled by a central clock seen on back wall (Fig. 9) and also on the plan (Fig. 11). Thus all the records are made simultaneously, all the record instruments—there are 48 of them—being absolutely in synchronism.

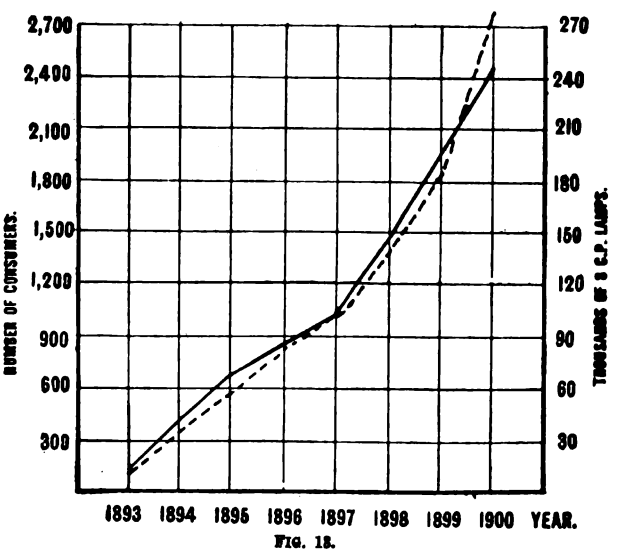

FIG. 13.

A side view of the board is given in Fig. 10, from which additional information will be gathered. The combined plug and switch gear, which can be moved into any one of the four bars, are seen near the floor; while the instruments, whose functions are too numerous to rehearse, are seen at the top. The signal levers, seen at the side of the measuring instruments, operate the switches seen on the back panel—this latter panel carries the double-break feeder switches, which, of course, are single-pole—and the duplex fuses easily seen in Fig. 10. From the latter the current passes to the feeders, which can be seen passing through the floor. Thus the circuits are not broken on the front panel although the switches are operated therefrom. A plan showing the general arrangement of the switchboard gallery and panels is given in Fig. 11. From the measurements it will be seen that this design has resulted in an unusually compact board.

The feeders pass down through the floor (as seen in Fig. 10) to the cable tunnel, which runs along the front of the buildings, and from thence they pass to the streets. The feeders are chiefly triple-concentric; nearly all have paper insulation, and are lead-sheathed. They are laid in wooden troughing on the solid system. The larger feeders have a section of one square inch, and at the time of ordering were the largest of their kind in the world, having an external diameter of $3\frac{1}{8}$in. The longest feeder is a little over two miles in length. The distributing system originally laid, copper strip laid on porcelain insulators in iron culverts, has been largely superseded by the solid system.

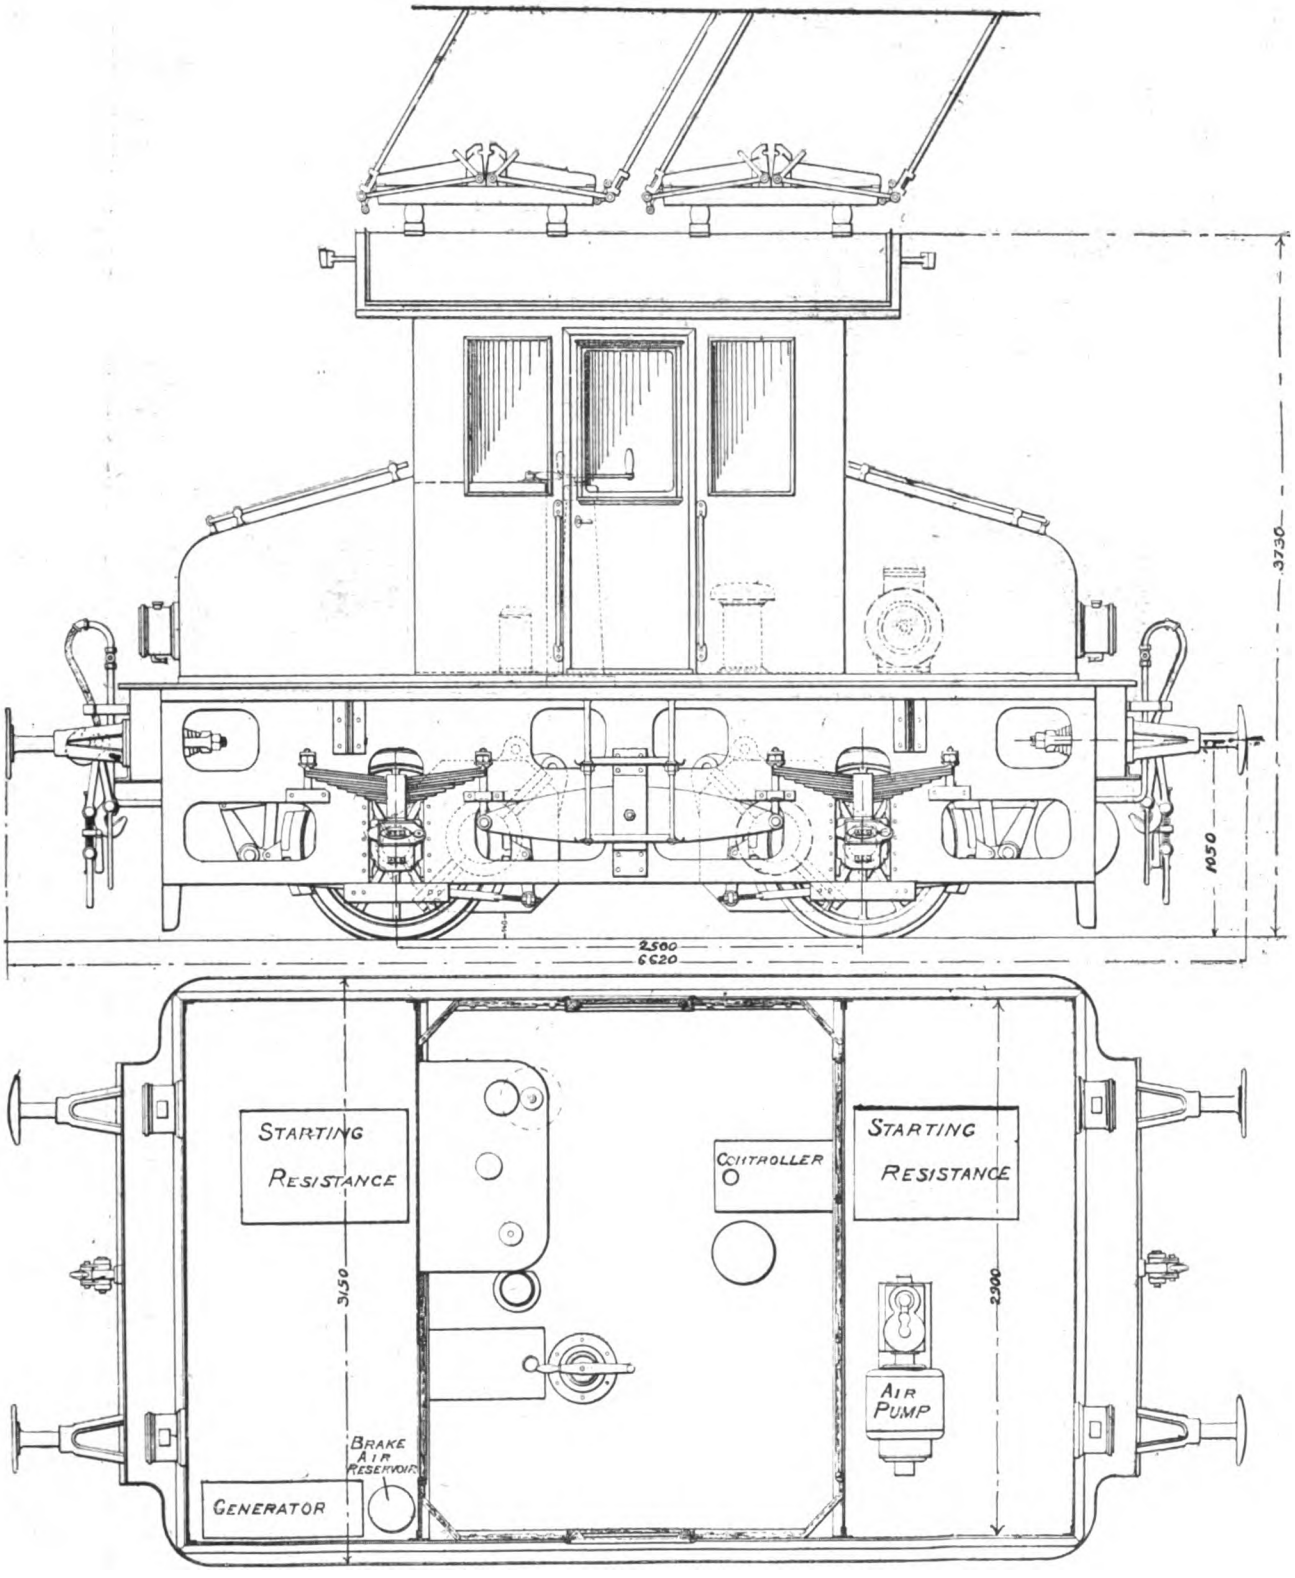
In order to show the development of the Glasgow system since its inauguration, two curves are given (Fig. 12) showing the progress of the undertaking in units sold and number of lamps connected: the broken line shows the former and the solid line the latter. Fig. 13 gives the number of consumers and their equivalent number of 8-c.p. lamps connected. It will be seen from Fig. 12 that the demand per lamp does not show any serious variation, but that each consumer has within the last two years shown a distinct tendency to use his supply for a longer period.

THE STANDARD-GAUGE ELECTRIC LOCOMOTIVE EXHIBITED BY THE ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT AT THE PARIS EXHIBITION.

The electric locomotive exhibited by the Allgemeine Elektricität-Gesellschaft at Paris, and herewith described, is designed for the haulage of goods and passenger trains on branch lines and for shunting purposes upon standard-gauge tracks. It is symmetrical in appearance, and constructed for the normal gauge of 3ft. 11in. The locomotive has two axles, each of which is driven by a separate motor. The general design of the locomotive is based upon the conditions prevailing upon the German State Railways. The locomotive is capable of hauling a train having a total weight of 300 tons at a speed of 28ft. per second, or 19 miles per hour on the level. The adhesive weight of the locomotive, included in the aggregate weight given above, amounts to 24 tons, its maximum tractive effort measured at the circumference of the driving wheel upon starting up being 8,000lb. With the exception of the roof of the driving cab, the footboard, and the inner lining of the driving cab, the locomotive is constructed entirely of iron and steel. The truck consists principally of two $\frac{5}{16}$in. frame plates, which constitute the longitudinal bearing girders, these latter being stiffened by means of channel-iron ends riveted with welded L-irons. Two buffers and a cow-catcher are attached to each end of this truck, the cow-catcher reaching to within $2\frac{1}{2}$in. of the bearing surface of the rails. There is nothing special to add with regard to the coupling arrangements, which conform to the standard practice in Germany. For constructive reasons the usual draw-bar is dispensed with; each coupling hook is therefore provided with a special spring attached to the buffer beam. The main frame plates carry iron brackets, with angle-iron strengthening pieces, which serve to support the upper construction of the locomotive. The whole truck is plated over with iron, whereby it receives considerable additional stiffening. The axle boxes are attached to the longitudinal bearers, as shown in the accompanying elevation. The distance between the axle centres is 8ft. 2in., which enables the locomotive to negotiate curves of the smallest permissible radius with ease. The wheels have a diameter on the tread of $39\frac{1}{2}$in., and are provided with wrought-iron spokes and cast-steel tyres forced on hot. The weight of the locomotive is transferred to the axle bearings by leaf springs, built up of separate ribbed laminations of steel $3\frac{1}{2}$in. broad by $\frac{1}{2}$in. thick, and held together in the middle by means of a wrought-iron truss. In order to distribute the weight as evenly as

Digitized by Google

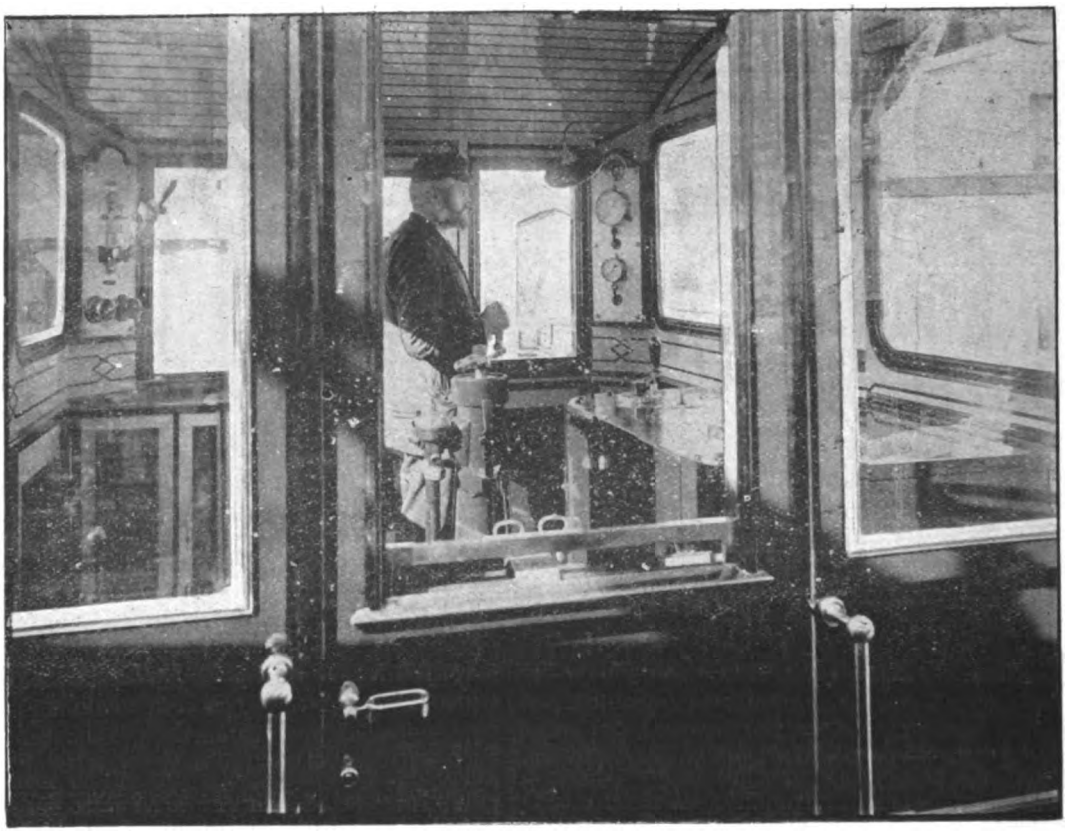
possible between the axles, each side of the frame is provided with a balancer which transfers a possible excess load upon one of the springs to the other spring. The spring suspensions are provided with adjustable nuts, whereby the trim of the buffers may be adjusted at any time. A screw spindle brake is further provided, which actuates two brake blocks upon each of the four wheels. There is also a Westinghouse air-brake, the piston of which actuates a lever attached to the main brake shaft. The necessary supply of compressed air is furnished by an air-pump driven by a special electromotor. The upper construction of the locomotive consists of the driving cab proper, and the sheathed compartment sloping off from either end of the same. The driving cab is protected, as shown in the accompanying illustrations. It may be entered from either side through a swinging door opening inwards, and fitted with windows which may be opened and closed as required. Each of the end walls of this cab is provided with three windows, while the side walls have two large windows each, of which the middle window in each end wall may be opened. Since the driving cab has an extreme breadth of 9ft. 6in., the whole train may be, therefore, kept under observation from the same. The sloping construction of the end compartments admits of an unobscured view of the track being obtained. The roof of the driving cab, as also the inner lining and floor of the same, consists of wood. In order to render the roof more durable, it is covered with waterproofed canvas. The apparatus for actuating the brakes is attached to a cast-iron pillar situated in the driving cab, and enables the eight brakes to be simultaneously put on. In the immediate proximity of this brake pillar are situated the levers in connection with the sanding pipes. Running parallel with each side wall of the cab below the windows is situated a



Plan and Side Elevation—A.E.G. Locomotive.

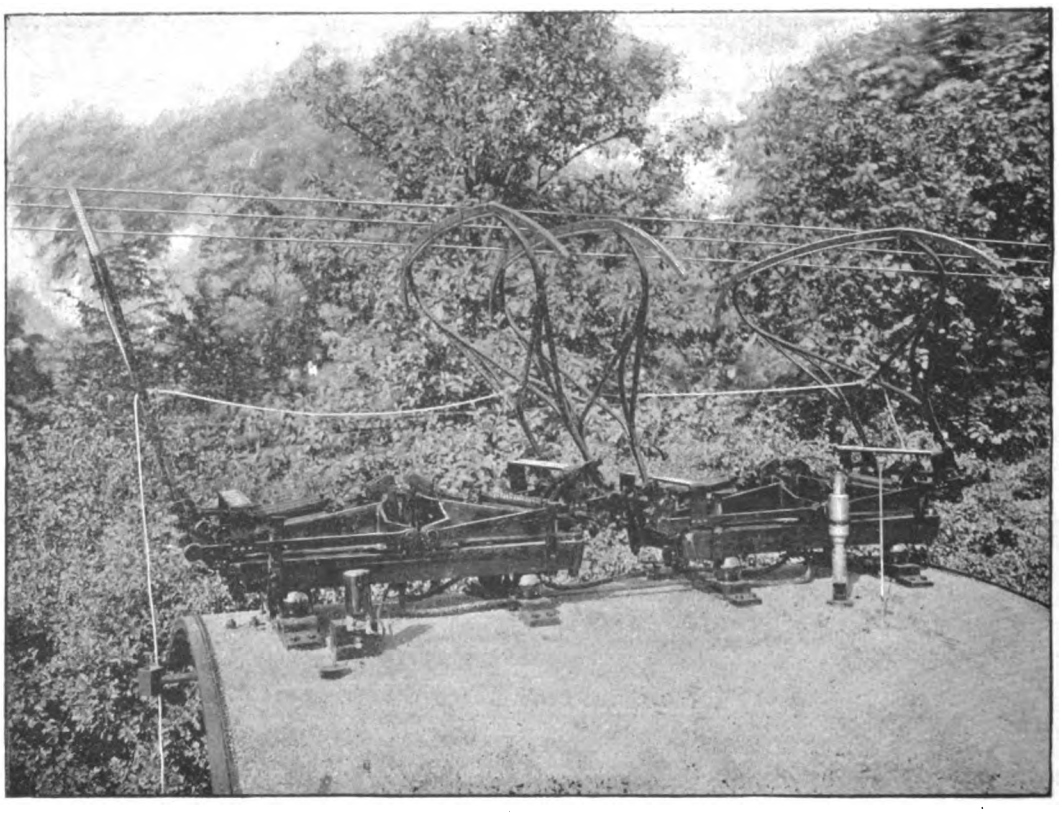
Digitized by Google

locker for the reception of tools and materials. For signalling purposes the locomotive is provided with a whistle actuated by means of compressed air supplied from a compressed-air chamber fed by the pump already mentioned. The floor of the cab is provided with trap-doors, through which the bearings of the motors, etc., are readily accessible.



View through Driving Cab—A.E.G. Locomotive.

An overhead trolley wire, suspended parallel with the track, serves to convey the necessary propelling energy to the locomotive. The current is collected from this wire by means of four contact bows attached to the roof of the locomotive, as shown. These contact bows are of special construction, whereby they adjust themselves automatically to either direction of travel. Having regard to the frequent change in the direction of travel, etc., the employment of a trolley wheel collector was out of the question here. The arrangement adopted for elevated and underground railways, consisting in the collection of current by means of a contact shoe from a conductor placed at the same level and running parallel with the rails, was also impracticable, since, on the one hand, insulation difficulties would have presented themselves, and, on the other, possible contact between the



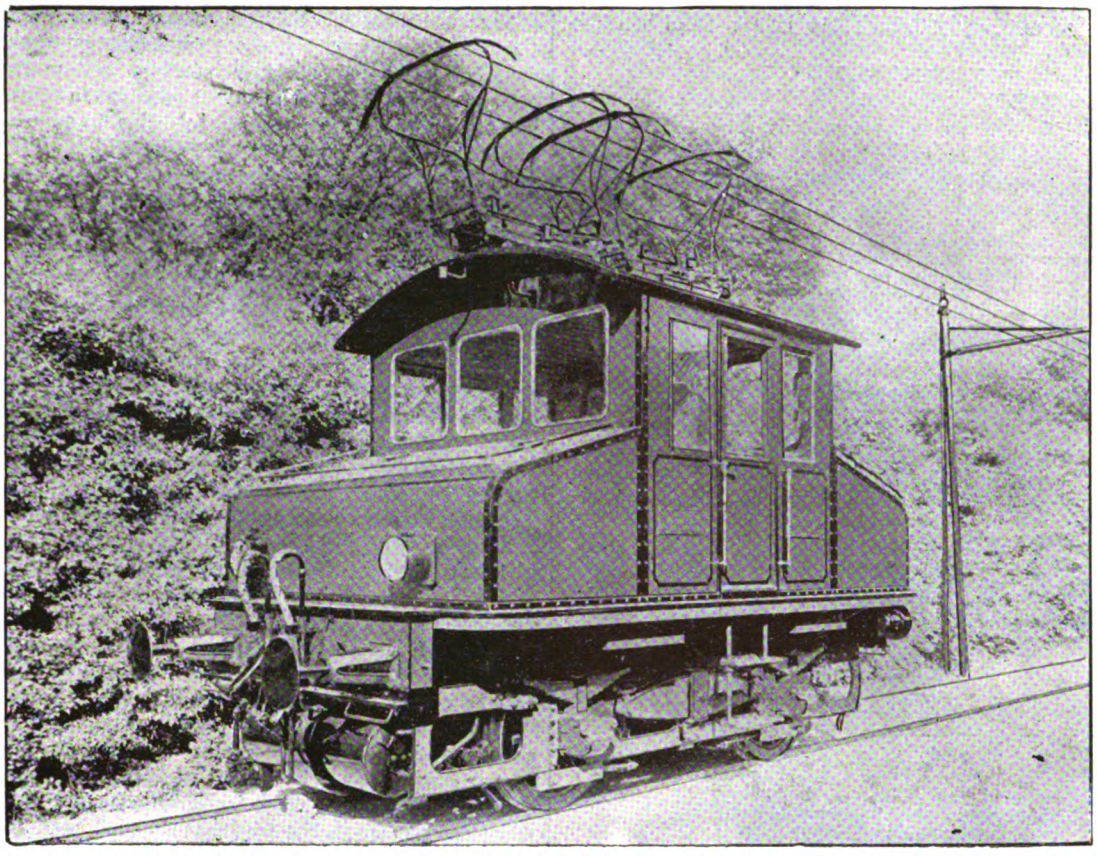
Bow Collectors—A.E.G. Locomotive.

Digitized by Google

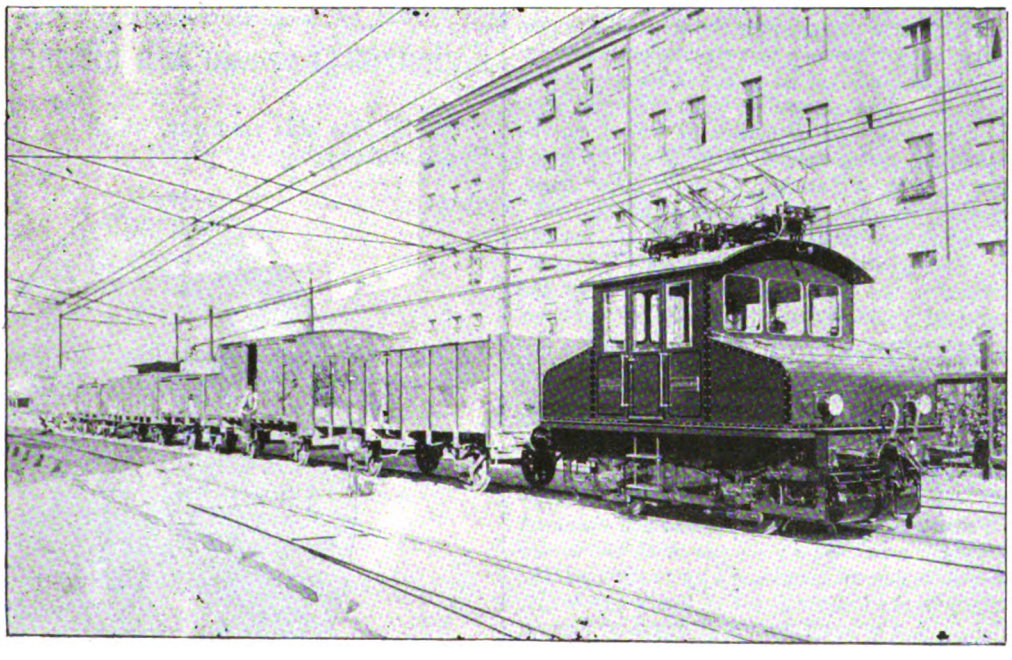
bearing rails and conductor could not be ignored. Further, at all points, crossings, etc., breaks in the conductor would be necessary.

In order to ensure good contact between the collector bows and trolley wire, the latter is divided into several parts consisting each of a single wire 8mm. in diameter. These wires are suspended parallel to each other as shown in the illustrations herewith, and are not insulated from each other. The wires are so suspended by means of special insulators that the sag in no case brings the wire down to less than 16ft. above the bearing surface of the rails. Wood or iron masts placed at intervals of from 100ft. to 130ft. along the railway serve to carry the trolley wire. The rails themselves serve for the return conductor, being bonded, and also connected to a special return cable where thought necessary. The locomotive is equipped with two motors of the A.E.G. V.B.-800 standard railway type. These motors are coupled by gearing to the driving axles, being suspended from the truck by means of springs in such manner that about one-eighth only of the motor's weight is directly borne by the axles. The driving power is transmitted from the motors to the driving axles by means of toothed wheel gearing having a ratio of 1 : 3. The driving pinion keyed to the armature shaft is composed of phosphor-bronze, whereas the large gear wheel keyed to the axle is of cast steel. The teeth of these wheels were were cut by special machinery. The gearing runs in a dust-proof oil bath formed by an iron case.

The motors are of the shunt-wound type, the steel magnet frame of each being so cast as to serve both as a protecting shield and to carry the bearings for the armature shaft, besides those for the driving axle. The motor cover is



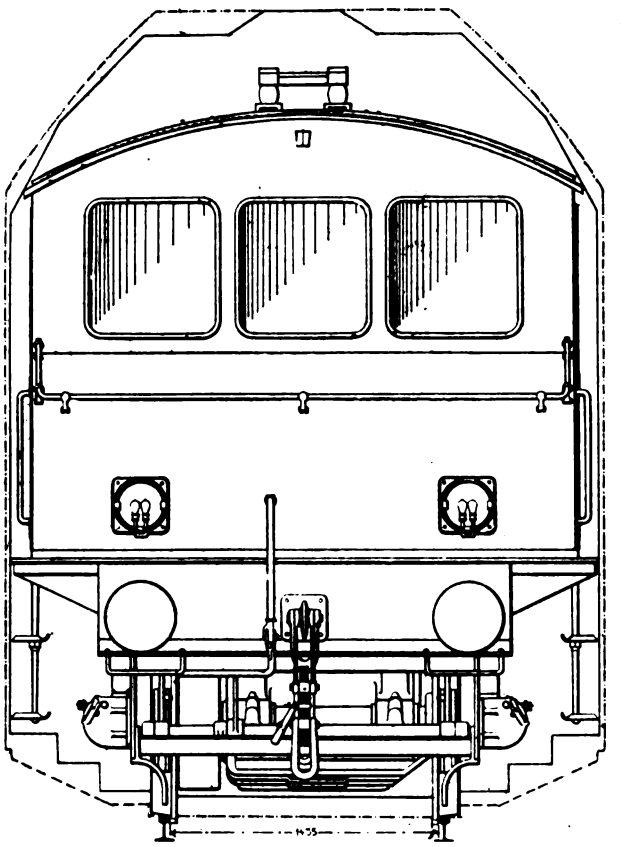
A.E.G. Locomotive.



A.E.G. Locomotive, with Train.

Digitized by Google

constructed in two parts, so as to protect the motor from damp and dust, and at the same time render the inner parts readily accessible. Both the commutator and the brushes are accessible through special openings. The armature is slot-wound, the coils being carefully secured. It is possible, without removing the upper portion or raising the locomotive, to detach the motor from beneath.



End Elevation—A.E.G. Locomotive.

The normal speed of the A.E.G. V.B.-800 type electromotor amounts to about 800 revolutions per minute, with a terminal pressure of 500 volts. Adjoining one of the end walls of the driving cab is situated the controller, which is arranged so as to enable the locomotive to travel either backwards or forwards. For this purpose the controller is provided with two cranks, one of which serves principally to regulate the speed of the locomotive, while the other serves as a cut-out and reverser. The controller is so arranged that the crank for determining the direction of travel can be reversed only when the crank serving to regulate the speed of the locomotive stands at "stop." On the other hand, the speed-regulating crank can be turned in the "on" direction only when the reversing crank stands exactly opposite either the "forward" or "backward" contact. The different speeds of the locomotive are obtained by the different grouping of the motors (series-parallel system), and by varying the strength of the magnetic field. For the low speeds the motors are switched in series, and for the high speeds in parallel. Compared with the system of regulating the speed by means of switching resistances in circuit with the motors, the system described above shows considerable economy. With the system in question the motors consume only that amount of electrical energy which suffices to overcome the work required from them A resistance, however, is switched in circuit with the motor upon starting up, in order to avoid a jerky motion of the train. But as soon as the locomotive has fairly got under way this resistance is switched out, and further loss of energy thus obviated. The starting resistance is situated in the sheathed compartments at either end of the locomotive, half in each.

The regulation of the strength of the magnetic field takes place automatically with the turning of the regulating crank, the necessary shunt regulator for this purpose being situated in one of the above-mentioned sheathed compartments. The aggregate output of the two motors amounts to 300 effective horse-power, the consumption of current corresponding to this output being about 550 amperes at 500 volts. The air-pump for supplying compressed air to the Westinghouse brakes, etc., together with its special driving motor, is placed in one of the sheathed end compartments. The air-pump is provided with a high and a low pressure cylinder, and supplies air at a pressure equal to six atmospheres. So soon as this pressure is attained in the main air reservoir, the pump motor is automatically switched out of circuit, coming automatically into action again when the air pressure in this reservoir has sunk to 5½ atmospheres. In order to enable the locomotive to work over stretches of line which for some reason or other may not have been equipped with overhead trolley wires, contact boxes are fitted to each buffer beam close to the coupling hooks, by means of which the locomotive may be coupled up to a special tender equipped with a battery of accumulators. The making of the electrical contact with the battery tender is accomplished in precisely similar manner to the coupling of brake tubes.

In the four corners of the driving cab are situated the necessary measuring instruments, etc., such as voltmeters, ampere-meters, switch levers, and cut-outs. In addition to the above-mentioned apparatus, the electrical equipment of the locomotive includes fuses for the protection of the motors and cable connections against overloading, and a lightning arrester with automatic spark extinguisher.

The lighting of the locomotive is provided for by means of 10 electric incandescent lamps arranged upon two circuits of five in series each. The head and signal lights, etc., are duplicated and placed on alternate circuits, so as to avoid complete failure of the lights at any one part of the locomotive. The principal dimensions of the locomotive may be gathered from the plan and elevation given herewith.

Experience has shown that shunting operations, etc., upon standard-gauge lines may be conducted at stations 40 per cent. cheaper by means of electric locomotives than with steam-engines. This favourable result owes its attainment principally to the fact that the cost both of the necessary energy and upkeep is much less in regard to electric working than with steam. Further, when electrical energy is employed, one man suffices to attend the locomotive, whereas two are necessary when steam power is used.

We understand that besides standard-gauge electric locomotives the Allgemeine Elektricitäts Gesellschaft have already constructed a large number of locomotives for factory sidings, light railways, and pit railways.

HOUGHTON-LE-SPRING AND DISTRICT TRAMWAY.

The Bill for this tramway, which has its centre about Houghton-le-Spring, was passed without opposition during

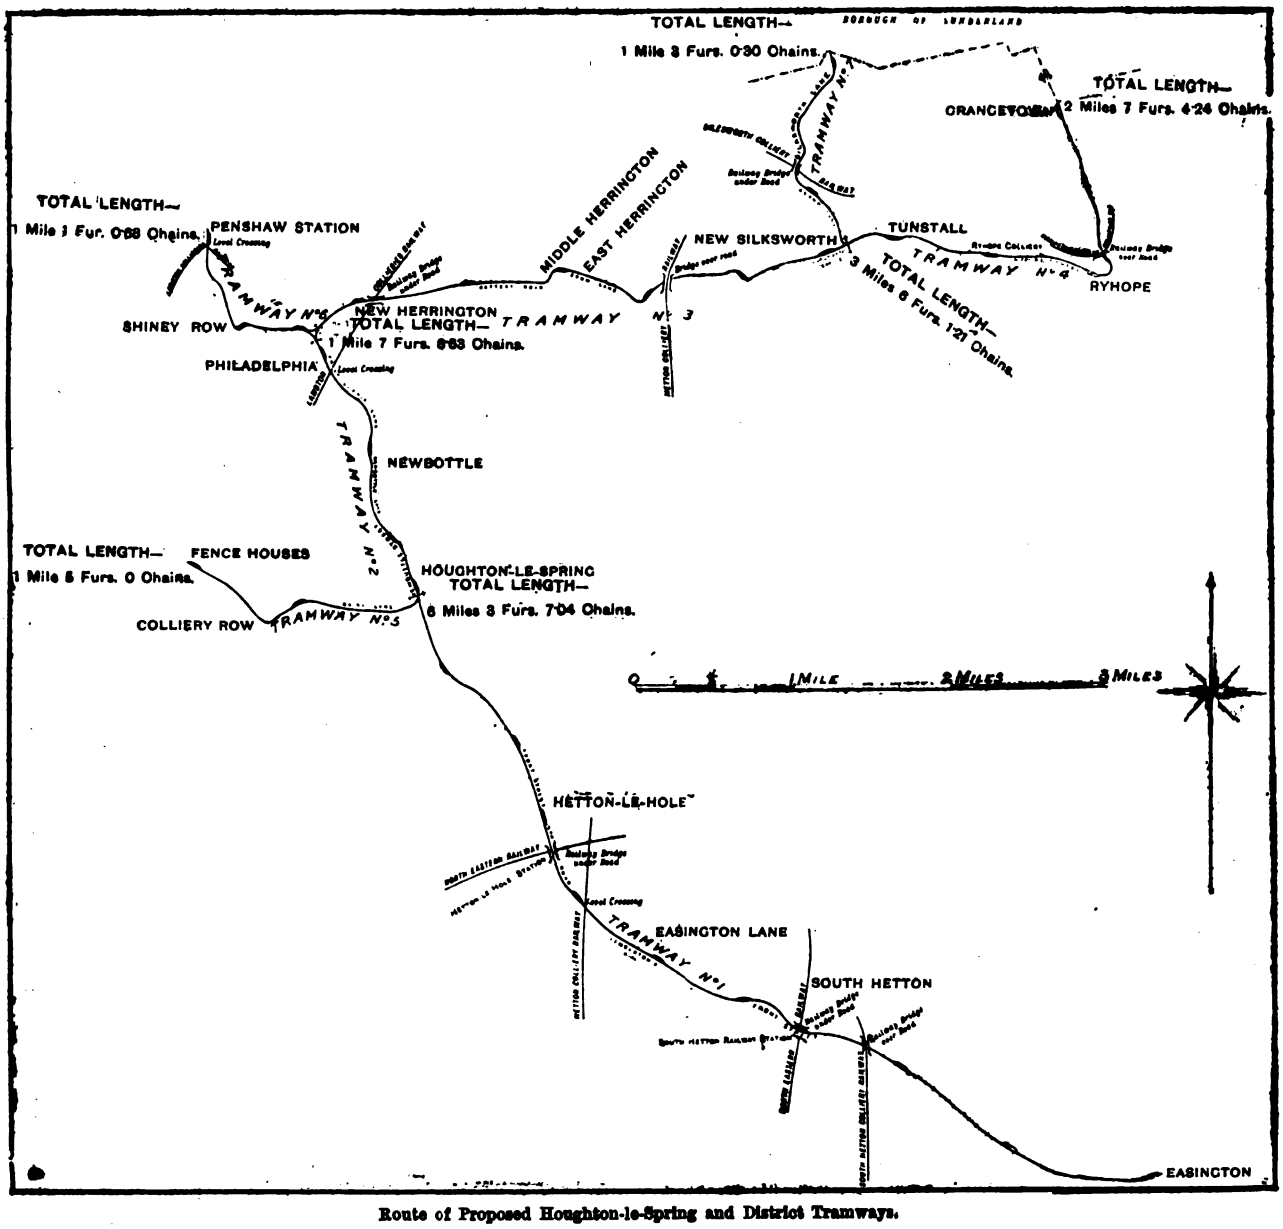
MR. D. BALFOUR, M.INST.C.E.

the last session. It has been promoted by the United Kingdom Tramway, Light Railway, and Electrical Syndicate,

Digitized by Google

and the engineer is Mr. D. Balfour, the well-known consulting engineer of Newcastle. The accompanying map will show the places which the tramway is intended to serve. It is expected that not only will there be a fair passenger traffic, but that there will be a fairly large goods traffic. The rate for this class of traffic, which accompanies the Bill, has evidently been carefully considered in order to develop as far as possible a large goods traffic.

In connection with this matter, we understand that the necessary ironwork will probably have to be obtained abroad, in that delivery cannot be guaranteed by any of the merchants in this country. If this statement is correct, it shows our manufacturers must be filled with orders, and that many of the alarmists' statements so often heard as to



Route of Proposed Houghton-le-Spring and District Tramways.

the decadence of British productions are the outcome of ignorance. We rather hope, however, that by the time active work is commenced that the materials required may be obtainable without bringing them across the sea.

CARDIFF PROPOSED ELECTRICAL TRAMWAYS.

The newly-appointed Corporation tramways electrical engineer, Mr. Arthur Ellis, in his preliminary report to the Tramways Committee on the equipment of the Cardiff tramways for electrical traction, briefly referred to in our columns of last week, remarks upon the Corporation's intentions to take over the present tramways on Jan. 1, 1902, when, in addition to the present lines, several miles of new routes will have to be laid and electrically equipped, whence the necessity of proceeding with the work without delay, there being only 15 months in which to do everything. In this respect Mr. Ellis points out that the plant must be completed and ready for testing at least a month or six weeks before the system is opened for regular service. The principal object of this preliminary report is, therefore, to enable the Tramways Committee to definitely settle the question of site for the power station and type of plant to be installed, which evidences wise forethought on the part of the advising engineer, having regard to the great difficulty in obtaining early deliveries of plant, etc. Hence the report is mainly confined to the question of site, the power station itself, and the plant to be installed therein. As regards the first question, what is known as the Roath Brook site is recommended for the power station. This site, it appears, has in its favour two most essential points—viz., close proximity to a railway, by means of which fuel may be delivered direct from the colliery, and also to a brook, from which water could be obtained for condensing purposes. Moreover, the site affords ample room for future extensions. Its position relative to the tramway system to be supplied with power involves no difficulties in the distribution of the power, the greatest distance from the site to the end of any of the proposed routes being under four miles, and even Penarth, which, as pointed out, may at some future date require a tramway service in connection with the Cardiff system, could be supplied with power from the same station.

With regard to plant, engines of the compound vertical condensing type, running at a speed not exceeding 100 revolutions per minute, and fitted with Corliss valve gear, are recommended for instalment, each engine to be equipped with its own condensing apparatus. Gene-

Digitized by Google

rators of the compound-wound type, mounted direct on the shaft of the engines between the high and low pressure cylinders, are further recommended. The generators would be constructed in such a manner that they could run as ordinary shunt-wound generators, if at some future time it might be desirable to use them for other purposes than tramways. The Roath Brook being of inconsiderable size, and not yielding a constant volume of water throughout the year, although there is a good flow for nearly nine months in the year, it is further recommended that a cooling tower should be provided for working in conjunction with the condensers, whereby the same water, minus any loss from evaporation, would be used over and over again. Besides making up any deficiency of water caused by evaporation, the brook water would be available for boiler feed purposes during the greater part of the year, when the boilers could be fed direct from the hot-well of the condensers, the loss being made up from the brook, whereby cooling apparatus would be saved through the condensing water being constantly mixed with fresh water.

As regards boiler-house equipment, the Lancashire type of boiler is recommended as being the most suitable for a tramway load. Economisers would be used in connection with the same. Superheaters and mechanical stokers, driven electrically, in combination with coal-conveying plant, are also mentioned in the report, the several advantages attending the use of the same being briefly referred to. The overhead equipment of the lines and system of distribution will be dealt with in the complete scheme which Mr. Ellis promises to lay before the Tramways Committee for their consideration at a later date; also the question of car depôts will be dealt with at the same time. The question of cars, having regard to the difficulty of obtaining the same in any number at short notice, will be taken in hand at once, and Mr. Ellis hopes to submit his suggestion both as to the type of car most adapted to local conditions and the number of cars necessary to the next meeting of the Tramways Committee. Mr. Harpur, the borough engineer, has the track in hand. As reported in our last week's issue, the Tramways Committee have agreed to purchase land adjoining the proposed site.

REVIEWS.

The Path of the Sun, its Orbit and Period of Revolution Demonstrated, with an Exposure of the Fallacy of the Precession of the Equinoxes. By WILLIAM SANDEMAN, F.C.A. Simpkin, Marshall, and Co. Pp. 132.

Mr. Sandeman is an iconoclast, and the little book before us shows that an idol may expect small mercy at his hands, unless, indeed, it happens to be of his own creation. For though we are told on the title page, "I do not frame hypotheses; I make no suppositions; I concern myself solely with facts;" yet Mr. Sandeman has an idol of his own, in the shape of a model of the solar system, and this he has frankly set on high, "in the confident hope of a friendly impartial reception" from "the great, tolerant, truth-loving British public." As an introduction, we are told that "there is no doubt that the discovery [which he has made] is a solution of the great astronomical problem of the day," even though it has been repudiated by the leading astronomical authorities.

Just a word as to iconoclasts in general. Scientific experts are not always right, and long-accepted hypotheses may be wrong, in detail or as a whole; but a justifiable conservatism leads us to defend our accepted idols until such time as they may be proved to be of clay. On the other hand, iconoclasts and innovators are not always right. Some, indeed, of our greatest scientists (notably Joule) have in their time had to struggle against adverse opinion for years, and have ultimately triumphed in the general acceptance of their cherished doctrines. But how many inventors of perpetual motion machines, squarers of the circle, and advocates of a flat earth, has the world not seen? *Peace to their hashes!*

Mr. Sandeman tells us that his study commenced in 1831, in which year "Ferguson's 'Astronomy' was perused, and a serious attempt made to understand it." However, "about the year 1886 doubts arose as to the accepted theory of precession being a true exponent of the cause of polar movements. . . . It thus became a settled point that, whatever the truth might be, it was not precession." This belief has grown with years, till it is now believed that precession "is the incubus on the solar path, a nightmare on the minds of astronomers, and an effectual bar to progressive discovery" (p. 77).

It may here be remarked that the mere term, "precession of the equinoxes," unduly excites Mr. Sandeman's censure. Yet this is merely a name given to an observed phenomenon which neither Mr. Sandeman nor anyone else is bold enough to question. The facts are these: The earth travels round the sun in an approximately fixed plane, termed the plane of the ecliptic. The plane of the earth's equator is inclined at a constant angle to the plane of the ecliptic. At the vernal equinox the centre of the sun lies in the intersection of these two planes, and is therefore vertically above a point on the earth's equator. The point in the heavens which the centre of the sun then occupies is termed the "first point of Aries." Now, it has been incontestably proved that the first point of Aries alters its position from year to year; by a very small amount, it is true—so small that only the cumulative effect of many years produces any observable difference—but still by an appreciable amount. The result is that at any particular equinox the sun has not yet quite reached the point in the heavens which it occupied at the previous equinox of the same name. Hence the equinox *precedes* the completion of the sidereal year.

The above is admitted by Mr. Sandeman; it is really the physical explanation given by Sir Isaac Newton to which exception is taken. Mr. Sandeman, unfortunately, has failed to realise that in this explanation Sir Isaac only applied an indisputable corollary of the second law of motion, together with the equally indisputable law of gravitative action, to a problem in celestial mechanics. That the causes mentioned by Newton are capable *in some degree* of producing the observed effect of precession, there can be no doubt, unless we are ready to abandon the whole superstructure of theoretical mechanics. Had Mr. Sandeman shown by calculation that the magnitude of the observed precession is too great to be accounted for by the cause invoked, then there would be just grounds for complaint if his alternative scheme were neglected. This, however, he has failed, or, rather, has never even attempted, to do.

Newton's explanation of the precession of the equinoxes, and the explanation of the conical motion of the axis of a top that is spinning in an inclined position, stand on exactly the same footing. If the top were not spinning, the action of gravity would pull it to the earth; as it is spinning, it possesses angular momentum about its geometrical axis, and the action of gravity further imparts to it an angular momentum about an horizontal axis. These two momenta must be compounded in order to find the resultant momentum, and the result shows that if the spin of the top be sufficiently high, its geometrical axis will remain inclined at a constant angle to the horizon, but will describe a conical surface, just as every schoolboy has observed his top to do. The result of the action of the gravitative attraction of the sun on the earth is essentially similar. The axis of the earth is inclined to the ecliptic, and since the earth has the form of an oblate spheroid, the differential attraction of the sun on the equatorial belt would pull the axis into a position perpendicular to the ecliptic if the earth were not rotating. As it is, however, the resultant angular momentum of the earth is due, not only to its momentum about its polar axis, but also to the angular momentum produced by the gravitative action mentioned above. Hence the polar axis of the earth describes a conical surface, just as a top does when spinning with an inclined axis. As a result, the equatorial plane, which is perpendicular to the polar axis of the earth, remains inclined at a constant angle to the ecliptic, but moves in such a manner that the line of its intersection with the ecliptic plane rotates in a sense opposed to that of the earth's revolution. Hence the precession of the equinoxes.

The above explanation is based on Newton's second law

Digitized by Google

of motion, and there is no logical ground for rejecting one unless we can disprove the other. When Mr. Sandeman writes (p. 35) that in postulating the conical rotation of the earth's axis "it becomes evident that the earth has somehow broken loose from the control of the sun, and turns itself independently of the influence of that orb," we can hardly avoid the conclusion that he has failed to master the fundamental principle of compounding angular momenta. "The extraordinary manifestation of the earth dancing a reel in face of the sun, turning round at the rate of once in 25,800 years," is matched almost every time a schoolboy spins a top. If Mr. Sandeman will take the wheel of a bicycle, set it spinning as fast as possible, and, while holding it with the axle horizontal, try to twist it into some new direction, he will be met by the "extraordinary manifestation," that, like a live thing, it apparently attempts to twist itself out of his hands in a direction at right angles to that of the desired motion.

As previously mentioned, Mr. Sandeman wishes, not only to demolish the accepted theory of the conical rotation of the earth's axis, but to replace this by a theory of his own. On the principle that "it's well to be off with the old love before you are on with the new," we need give no detailed account of Mr. Sandeman's theory; an examination of the foundations on which this is erected must suffice at present. In brief, his theory is that the sun is travelling in an approximately circular orbit of about three billions of miles in diameter, one revolution requiring 25,800 years. It is known, from observations of the apparent drift of stars, that the sun at present really is moving, with a velocity of from six to eight miles per second, in the general direction of Alpha Lyræ. The true curvature of the sun's path is not known, as it could only be determined with certainty from observations extending over several thousand years. We will now let Mr. Sandeman speak for himself, premising that the extract given follows on a vigorous onslaught against the accepted theory of precession. The "forces" mentioned are the centrifugal force due to the earth's rotation (which really has nothing whatever to do with the question) and the gravitative pull of the sun on the equatorial belt of the earth:

"The theory presented in opposition to this—*i.e.*, to Newton's theory—is that the two forces acting together hold the earth in a fixed position in relation to the sun, and if the similitude can be used in reference to loose bodies moving in space, they act as if these bodies were joined by an iron bar. As the sun revolves in his orbit, therefore, the earth and its axis must turn with it; but as the revolution of the sun also involves its revolution round the earth, the equinoctial points on the earth's surface—that is, the places where the sun crosses the equator—must advance with the sun" (p. 36).

We are afraid that the reader will attain no very clear ideas from the above, but no passage of similar extent which we have been able to find appears preferable. From a comparison of a number of passages (see pp. 33, 53, 95, etc.) we believe that the meaning of the author is as follows: The sun is supposed to revolve in an orbit, as previously mentioned, in a plane slightly inclined to the ecliptic, or plane of the earth's orbit. Let us suppose, for instance, that the earth's axis at any time cuts a straight line drawn perpendicularly through the centre of the sun's orbit. Then, as the sun revolves, the earth will move so that its axis always cuts the line mentioned (neglecting the parallel displacement of the earth's axis during its yearly revolution). Hence the earth's axis will, as in Newton's theory, describe a conical surface in 25,800 years, the period required for the sun's revolution; "an extraordinary manifestation," of which the author attempts no mechanical explanation.

It is, perhaps, only fair to give Mr. Sandeman's "proof" of the mechanical principle on which his theory is founded. The plane of the moon's orbit is inclined to the plane of the ecliptic, and the line of intersection of these planes is termed the "line of nodes." Now, it has been observed that the line of nodes rotates once in every $18\frac{2}{3}$ years. This rotation of the moon's line of nodes is accompanied by a small conical motion of the earth's axis, also occupying $18\frac{2}{3}$ years. In the following extract the "nodes of the sun" must be understood to refer to the points in the ecliptic through which Mr. Sandeman supposes the sun to pass in its (conjectured) orbital motions. Now (p. 34), "if the sun revolves round an orbit and round the earth, both of which are admitted in theory by astronomers, the effect of the revolution of the nodes of the sun upon the pole must be the same as those of the moon, in which case the pole must be carried round with the sun in the same time as it revolves itself."

For a short statement the above abounds in fallacies. First of all, the revolution of the nodes of the moon produces a small conical movement of about 18 seconds of arc in the earth's axis, *about what would be its position if undisturbed*; hence it is concluded that the revolution of the nodes of the sun produces a conical motion of 47deg. *about an axis perpendicular to the ecliptic.* But another fallacy lies behind. We are first told that the revolution of the *nodes of the sun* carry the earth's axis round once in every revolution, and then that the revolution *of the sun itself* does the same thing. Now, whilst the moon's nodes make one revolution, the moon makes about $12 \times 18\frac{2}{3} = 224$ revolutions; why the nodes of the sun are tacitly supposed to revolve in the same time as the sun itself we are not told.

Perhaps the above will be enough to indicate the scope of the book and the nature of the arguments used. We are not without sympathy for Mr. Sandeman's aims, but we think that he was badly equipped for the task undertaken. His honest and sincere enthusiasm for the acquisition of truth is sufficiently apparent, even though this is often clouded by a want of appreciation for the work of eminent astronomers. Many of his errors may be traced to a defective knowledge of mechanics and astronomy, due to the use of popular treatises on these subjects. The sort of knowledge which it is possible to impart in a popular lecture or treatise is apt to prove insufficient to enable anyone to criticise or construct a theory. A short but satisfactory account of the motion of the earth, treated mathematically, may be found in Routh's "Rigid Dynamics," paragraphs 610-634. It is there shown that the sun produces a precessional motion of 15·42 seconds of arc per annum, that due to the moon being a little more than double this amount. As in some other cases, the actual figures obtained by Newton were not correct, although the method which he introduced has, in the hands of his successors, led to accurate results. This is not to be wondered at. The work of a pioneer is to make a road, and not to build cities. Mr. Sandeman is mistaken in thinking that a theory would gain immunity from criticism on account of its having been proposed or accepted by Newton. To go no farther, Newton made a serious error in calculating the velocity of sound in a gas, and rejected the wave theory of light in favour of the corpuscular theory; these facts may be found stated in any advanced text-book. A theory which cannot bear criticism is not likely to stand, no matter who the founder may have been. But in the present case Mr. Sandeman has failed to disprove the accepted theory, and has failed also to substantiate his own. There we may leave the matter at rest.

EDWIN EDSER.

FORTHCOMING EVENTS.

FRIDAY, SEPT. 28.

Royal Photographic Society.—Press view of forty-fifth annual exhibition, from 11 a.m. to 4 p.m.

SATURDAY, SEPT. 29.

Royal Photographic Society.—At 8 p.m., at the New Gallery, Regent-street, soirée in connection with the annual exhibition.

MONDAY, OCT. 1.

Society of Engineers.—At 7 30 p.m., meeting at the Royal United Service Institution, Whitehall. A paper will be read, entitled "Paper-Making Machinery," by Mr. Robert Henderson.

WEDNESDAY, OCT. 3.

Society of Model Engineers (Liverpool Branch).—At 7.45 p.m., monthly meeting.

THURSDAY, OCT. 4.

Civil and Mechanical Engineers' Society.—At 8 p.m., first monthly meeting. Presidential address on "Training to keep ahead in the World's Competition," by Prof. R. H. Smith.

SATURDAY, OCT. 6.

Association of Municipal and County Engineers.—District meeting at East Molesey and Hampton.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	5s. 6d.	10s. 6d.	21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered, price 8s. 6d.

POSTAL TELEGRAPH FINANCE.

The annual report of our Postmaster-General was issued rather more than a month ago, so that it now has had time to reach most of the foreign countries. The comments on this report are hence to be expected in the technical Press of these countries, and we see in our contemporary, the *Western Electrician*, the following verdict on the same: "The British telegraph service is admittedly very good—better, on the whole, no doubt than that of our private companies. But why should that portion of the British public that does not use the telegraph be taxed to meet the deficit of those that do?" Assuming that the verdict of our contemporary on the financial position of the postal telegraph system of the United Kingdom to be a correct one, we should still object to the query at the end of it on the following grounds. Any telegraph system, and particularly a cheap and efficient one, is of such advantage to the commercial world that the benefits conferred are not by any means confined to the actual users. For instance, in a large manufacturing business the telegraph system has now become an absolute necessity, and while the artisans and labourers employed by the firm may not use the telegraph themselves to any large extent, they indirectly receive a great benefit. It is, however, with the general criticism of the *Western Electrician* which we have to deal, and we were surprised to find that this was based on an editorial comment on the report which appeared in the columns of our neighbouring contemporary. As this contemporary is run by a business man, one would naturally expect a reasonable comprehension of the Post Office balance-sheet. The system adopted by the Government in extending its telegraph business is quite unlike that in vogue amongst commercial enterprises, who have to make a return to shareholders each year. In this, we presume, may be found the explanation of our contemporary's most misleading remarks, which are as follows: "Summed up briefly, although the telegraph revenue increased by £200,347, the expenditure also increased by no less than £266,916, resulting in a net deficit of £288,438, or £66,569 more than last year's deficit. If allowance be made for interest on the capital created for the purchase of the telegraph, the deficit for the year is raised to £587,326." Our contemporary goes on to comment that "every year this painful fact is rubbed in with unsparing reiteration, but without the least attempt of explanation or expectation of amendment." One would have thought that the explanation would have been given by the editor of a journal specially devoted to telegraphic undertakings. The facts of the case are as follows: When the Government took over from the various companies the telegraph works which are now united to form the telegraphic system of the kingdom, Government stock was issued in order to obtain the purchase money. The amount of the stock is now practically the same as in the year when it was issued, and the interest on it each year amounts to £298,888. When extensions were required, as has been the case each year, the policy of increasing the capital account was not adopted,

Digitized by Google

so that in the figures quoted above, items appear which can by no means be considered as working expenses. For instance, the telegraph extensions for the past year alone cost £277,133, a large portion of which went in the provision of telephone trunk wires, on which £176,968 were spent. Buildings and new sites were also provided at a cost of £76,097. It is, in fact, clearly pointed out in the tabular account in the report that a profit of £65,592 was made on the working of the telegraph system. This is, of course, insufficient to meet the interest charges on the stock above mentioned. A more equitable way of considering the case is to take the average for the last ten years, which shows that out of interest charges amounting to almost £3,000,000, about £885,000 has been met by the net revenue of the Department. This leaves a deficit of, say, £210,000 per annum, which is the real average deficit, and which does not compare at all with the apparent deficit of £587,000 quoted by our contemporary, and which exists on paper only. The difference between the two is capital expenditure, which the Government, rightly, in our opinion, considers should be borne by the present generation, which has almost immediately the benefit of it. For this capital expenditure the country holds a tangible asset, which is worth considerably more than its cost price to the commercial men of the kingdom. If further comparison were needed as to the wisdom of the policy of extending the system out of the national revenue, it could be obtained by comparison between the cost of a telegraph message here and in the United States. We pay for twelve words sixpence. In the States, while the telegraph companies are not earning extraordinarily large dividends, the cost of a message of the same length would be elevenpence halfpenny. On this comparison of cost, the Government saved the English nation £3,000,000 last year in cost of telegrams by a system which involves an actual expenditure for working expenses and capital charges of something like £200,000 per annum.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTROMAGNETIC INDUCTION.

SIR,—I am sorry, for Mr. Johnston's own sake, that he has not the decency to apologise for having misrepresented me, but merely says that the misrepresentation, which he does not deny, "in no way affects the main points at issue." It affects the matter in this way: By representing me as saying "current" where I said "E.M.F.," he was able to destroy my case completely, and to prove that I had "found a veritable mare's nest." He now complains that I misrepresent him when I say, "He then goes on to show that the statement to which I object does not imply that there will be a current under such conditions." But this is not a misrepresentation at all; indeed, it is obvious that if he did not show that the statement does not imply a current, he would not be in a position to ridicule my alleged idea that it does imply a current. If his argument is not as I represent it to be, it has no force whatever; but a reference to the second paragraph of his first letter will show that he does exactly what I say he does.

I pointed out an extraordinary *non sequitur* in his first letter, and he now replies: "I would point out that the statement of two propositions does not necessarily imply that the one is a deduction of the other." But when you connect the two propositions in this way, "*Remembering that* A is B, *it is evident that* C is D," you do imply that the second is a deduction of the first, and it is Mr. Johnston's use of the words italicised which justifies my criticism. I will now come to the main point at issue, for on the remaining point Mr. Johnston clearly answers himself when he says "the *strength* of the field at any point is represented *not* by the lines, but by the *number* of these lines passing through unit area at that point."

The main point is this: I have said, on the authority of Faraday, that the mere cutting of magnetic lines does not tend to induce a current, but that there must be a change in the number of magnetic lines passing through the electric circuit. Mr. Johnston, like the editor of *Lightning*, suggests that I have misunderstood Faraday. In reply to this, I can only say that some of the best-known writers on electricity are of the same opinion as myself regarding Faraday's theory. This is what Prof. S. P. Thompson says in giving an account of that theory in the fifth edition of his book on "Dynamo-Electric Machinery," p. 27: "It is, however, necessary that the moving conductor should, in its motion, so cut the magnetic field as to alter the number of magnetic lines that pass through the circuit of which the moving conductor forms a part. Without a variation in the magnetic flux that penetrates the circuit, there will be no induction."

Prof. Fleming, in the introduction to his book on "The Alternate-Current Transformer," shows that he too understands Faraday's theory in this way. It will thus be seen that I am by no means alone in condemning the inaccurate manner in which the theory is usually presented to students.—Yours, etc.,

W. F. DUNTON.

ELECTRICITY IN THE INDUSTRIES.

BY PROF. S. P. THOMPSON.

Prof. S. P. Thompson, who was selected to deliver the "lecture to artisans" in connection with the British Association, took as his subject "Electricity in the Industries." In his address he opened by speaking of the growth of Bradford during the 30 years since the last British Association meeting was held there. He stated that the population of Bradford had doubled since then, and that its prosperity was in a great measure due to the invention of the steam-engine and its application to the textile industry. He then went on to speak of the rise during recent years of the electrical industry, and of its application to heavy work. He then showed the leading inventions which had combined to give the electrical applications of the present day. Thus Sir Humphrey Davy put the first two sticks of carbon together and produced the electric arc light; William Sturgeon, a native of Kirkby Lonsdale, invented the electromagnet; Michael Faraday discovered the commercial and mechanical way of generating electrical currents in a magnetic way. The experiments by which these inventors arrived at their great conclusions were reproduced by Prof. Thompson, who showed their relation to the other inventions in the production of the great electric power stations and appliances of to-day. Faraday's ring, for instance, was the prototype of all transformers since made, and which were solving the problem of the economical transmission of power over long distances. Prof. Thompson then had thrown upon the screen photographs of dynamos and motors, of railway engines and tramcars, representing electrical science so far as it has gone. Some small experimental dynamos and motors were also exhibited on the platform. The lecturer then went on to describe great modern generating stations, such as those at Niagara and on the Rhine, where the current is sent at a very high pressure over comparatively long distances, and then transformed down into currents suitable for domestic lighting and similar purposes. Prof. Thompson referred to the Bradford tramway system, and said he was wondering when all the Bradford trams would be electrical. He spoke then of the enormous value which coal in the future would have for the purpose of raising steam to transmit power over long distances, and thought that in the coming age of electricity the workers would have a much better time than at present,

DISCUSSION ON IONS.

On Tuesday, Sept. 11, a joint discussion was held at Bradford between Section A and the Chemical Section of the British Association on the subject of "Ions."

This was opened by Prof. G. F. FITZGERALD, who treated the subject in a very broadminded way, and suggested various experiments which should be made in order to elucidate the various uncertain problems connected with electrolysis and the migration of ions. In the first place, he held that the term conductivity was preferable to ionisation. Thus the conductivity in a liquid solution was distinctly different from the conductivity in a gas. In gas, for instance, there seemed to be evidence, as shown by Prof. J. J. Thompson, of masses smaller than atoms, whereas there was no such evidence of smaller masses than atoms in liquids. Besides this, there was a fixed relation between the conductivity of liquids and their other properties, such as their solution, their chemical affinity, and their freezing and boiling points. Prof. Fitzgerald proceeded to point out that they really had not, at the present time, a satisfactory theory to account for the phenomena in ionisation. Amongst the difficulties which were met with in the usual theories, and of which these theories could not give a sufficient explanation, were the stability of ions, the source of energy of ions for dissociation, and the migration of ions with different velocities. German physicists were quite content with the term ionisation, and were rather strict in their orthodox acceptance of the same. He proceeded to point out that hydrogen and chlorine ions seemed to wander about in a solution without any tendency to recombine, which is quite inexplicable by the usually accepted theories. Coming now to the gases, little was known until recently of the conductivity of gases until it was studied by means of X-rays, etc. He hoped that the information obtained would be extended. He suggested that the term ionisation should only be used to denote that charged atoms existed, and he proposed that the word electronisation should be employed to denote the state of a gas acting as a conductor in which there were free electrons. He pointed out that it was probable that both ionisation and electronisation occurred in a gas, and referred to the wonderful work done by Prof. J. J. Thompson in determining experimentally and mathematically the behaviour of an electron, which seemed to consist of small corpuscles connected in some way with the molecules. He then referred to the light which the Zeeman effect threw on the subject. He mentioned that there was not sufficient evidence to justify the assumption that atoms consist of the combination of a number of electrons. The best evidence towards this end was the change in size of objects when moving through ether. According to Michaelson's calculation, this change of size was of the order of 4cm. in the diameter of the earth in consequence of its motion through ether. Amongst the questions which further experiments would decide was that of the influence of gravity on ions. In the old days it was recognised that the internal work in a primary battery ought to be varied by the position of the plates in the same. For instance, if the zinc plate in a Daniell cell was placed horizontally on the top of the salt and the copper plate also placed horizontally on the bottom, the work done should be less than if the reverse were the case. An interesting experiment would be to enclose a copper sulphate solution in a receptacle with the two opposite sides of copper, and then to whirl the same round at a very high speed to see if the centrifugal action caused the ions to be deposited on the outer plate and set free from the inner plate. This would, of course, be evidenced by an electric current. He suggested the following points as ones to which the meeting might give its attention in the discussion which was to follow: (1) The cause and end of ionisation, and why the ions did not exist in pairs. (2) Where the energy comes from which keeps the ions apart, as, for instance, gas ions do not recombine readily. (3) Why ionisation does not obey the law of dissociation. (4) The question of the rate of migration of ions, and why it is different with different elements. (5) What is the end of the double layer of ions which occurs in electrolytic salts, and why the action of gas and liquids in this respect is not the same. (6) Do electrons gravitate? (7) The theory of magnetism and paramagnetism. He thought the last would throw much light on the subject.

Dr. J. LARMOR, the president of the section, suggested that the specific inductive capacity of water might be high in consequence of the electric moment of the molecule being high. This might be the cause if the positive and negative ions were studied at the end of an axis of considerable length in comparison to its breadth. He pointed out that, in spite of the different velocities of the migration of ions, the combining proportions were maintained by the conductivity of circuits.

Prof. H. E. ARMSTRONG alluded to the value of a joint discussion on this important subject, and considered it absolutely sinful that it should be held without provision being made for a verbatim report, so that the remarks of the various speakers should be considered at leisure. It was the first time that they had had a rational discussion between chemists and physicists on the question. The German schools were so fixed in their ideas that a discussion with them was absolutely impossible. The question of the structure of the atom was one which the chemist did not like to consider as being easily effected, and the evidence obtained in chemistry pointed the other way, but in spite of that very little was known of the inner structure of the atom. He believed that the conductivity in gases was due to much the same process as in liquids, and that it was almost impossible to get conductivity in a gas without a vapour being present. He thought that an explanation was required of the association of ions quite as much as of the dissociation.

A manuscript was then read from Mr. WHETHAM on the possibility of ions, which are considered as free, being actually handed from molecule to molecule as suggested by one of the older theories.

Dr. O. J. LODGE agreed with Prof. Fitzgerald in his suggestion that in the conductivity of gases, both electrons and ions were involved. He remarked on the ascertained fact that, although the velocity of ions varied considerably with different elements, the velocity of electricity was constant. He expressed the hope that the electric theory of matter would eventually be confirmed by further experiment.

LIGHT RAILWAYS.

At the last meeting of the Canterbury General Purposes Committee, the Town Clerk mentioned that two parties were applying for powers to establish light railways—one was for a line from Canterbury to Whitstable and Herne Bay, and the other from Herne Bay to Canterbury. Plans will be laid before the Council. The announcement was received favourably.

At the last meeting of the Broadstairs and St. Peter's Urban District Council, the engineers to the Isle of Thanet Light Railway submitted plans of line No. 8, authorised by the order of 1898. They also sent plan of posts for carrying overhead wires. With reference to the Council's suggestion for interlacing lines to be substituted for the double line in Victoria-parade, plans were sent in showing line as proposed by the company and also the position that would be occupied by interlacing lines, which they considered for such a short length would not be any advantage. The letter was referred to the General Purposes Committee.

The Commissioners held an enquiry on the 25th inst. at the Blackburn Town Hall into the application for an order to authorise the Blackburn, Whalley, and Burnley light railways.

After holding a public enquiry at Rhyl on Saturday last the Commissioners decided to sanction the construction of an electric tramway from Prestatyn to the Marine Lake, Rhyl, a length of about seven miles. The capital of the company is £7,500, and the Rhyl Council will supply the electricity. There was no opposition to the scheme, which is to be completed by next season.

The General Election.—We notice that in the forthcoming election Mr. F. H. Medhurst, whose name will be well known to many of our readers, is standing for West Islington. Apart from any party question, we wish him success in his candidature, as it is very desirable that the important electrical industry should have a representative in Parliament, more especially in view of the large number of electric lighting and traction schemes now being started all over the country.

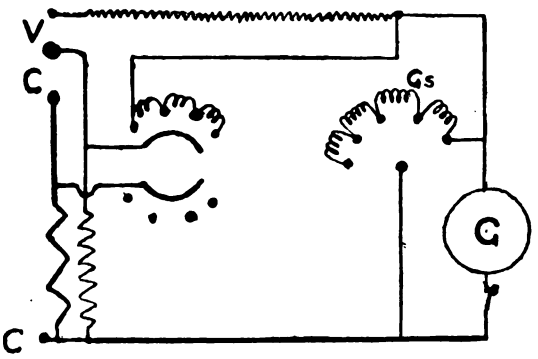
A LECTURE-ROOM VOLT AND AMMETER.*

BY PROF. BAILY.

The author exhibited a compact arrangement of resistances and connections which he has devised for employing the D'Arsonval galvanometer as a laboratory-room volt and ampere-meter. These resistances and connections are contained in a box which is small and portable. The connections are illustrated in the diagram, from which it will be seen that the galvanometer is used in series with a large resistance when measuring volts, in which case the galvanometer is shunted to enable variations in scale to be obtained. The exceedingly wide range obtained will be gathered from the following figures: When the galvanometer is practically in series with the resistance across the voltage to be measured the full scale corresponds to one-twentieth of a volt, while with the shunt switch moved over to the right the range of the scale corresponds to 300 volts. For measuring current the connections are those used for potentiometer work, and two resistances, which are carefully calibrated, are provided, through one of which the current to be measured is passed.



The connections of this end are shown in the illustration. The range, as far as current is concerned, varies from ·15 ampere for the full scale deflection up to 30 amperes. It will be seen that this allows accurate readings to be taken down as far as one-half of a milliampere. In the same way, the voltmeter arrangements are sufficiently sensitive to allow of thermo-electric force being measured. For the galvanometer, which is, of course, independent of the boxes, Prof. Baily uses one of the D'Arsonval type with a fairly low resistance. The scale for the same he makes about 6ft. long, so that a clear reading can be obtained, which is visible to everyone in a lecture theatre. The author was complimented by the president on the arrangement of the instrument.

ELECTRICITY SUPPLY FOR LIGHTING AND TRAMWAYS, WITH SPECIAL REFERENCE TO SMALL TOWNS.†

BY HORACE BOOT, M.I.E.E., CONSULTING AND RESIDENT ENGINEER TO THE TUNBRIDGE WELLS CORPORATION.

A local authority having obtained powers, the following questions immediately crop up: (1) selection of site; (2) choice of system; (3) the question of an expert to advise; (4) the extent of area of supply; (5) the capacity of the generating plant; (6) should street-lighting be undertaken? (7) the price of supply, and whether a rebate should be given according to the consumption of electricity; (8) should free wiring be undertaken.

The difficulties presented in supplying small towns as compared with large ones are manifold, and it may be taken as a general rule that it is much easier to supply large towns in a successful manner than small ones. There are at the present moment a number of small towns which are hesitating as to whether it would pay them to undertake the work themselves, or to allow a company to commence operations, and, as the local conditions in each case must be carefully studied before a reliable and correct decision can be arrived at, it is advisable to call in an expert to draw up a report. For large towns it is almost always advisable that the local authority should start their own undertaking, both for lighting and traction purposes.

The vexed question of a combination of power stations—capable of supplying electric energy for tramways, motors, lighting, heating, and other industrial purposes—has been discussed very frequently for the past two or three years, and for those members who desire to possess a more intimate knowledge the author would recommend them to read the papers that have been written on the subject by various writers; but there is no doubt that whatever that, wherever it is possible, there should be one power station to supply the whole area, and the policy of multiplying these power stations is incorrect from an economical as well as a practical point of view. A number of towns have thought it advisable to separate the production of electricity for tramways and lighting into different works, which they will find in the future has been a mistake, and has only been brought about by the fact that in all probability the original site selected for the lighting works was badly chosen and unsuitable for future development for the supply of electric energy on a large scale. Only those who are intimately associated with the industry can appreciate the difficulties experienced in obtaining a good supply of fuel, and works should never be placed in such a position that fuel can only be obtained by carting. The site should be selected, if possible, where a railway siding can be obtained, or "water-borne" coal can be used.

An important point to bear in mind is also the question of nuisances, as works of any magnitude cannot be run without creating a certain amount of nuisance, such as smoke, vibration, and noise; and the author ventures to think that if the sites already selected for the supply station were again considered, a large number of them would prove to be unsuitable, hence their necessity for constructing more than one power station. There are, of course, certain conditions which arise in towns necessitating the adoption of more than one power-house, but the author is of the opinion that the future will see the development of large power stations supplying large areas, in preference to little stations supplying local areas. The advantages of such will be: facilities for obtaining fuel; all nuisances localised to one spot; the advantage of water carriage, with an adequate supply of water for condensing purposes; the small amount of labour required for one works to work successfully, as compared with that for a number of small works; the advisability and advantage gained by having the staff in one place. The only objection that can be raised to it, is the question of fire or total disablement of the works, causing a complete stoppage of the supply. The likelihood of fire should be impossible if the works are properly designed—as nothing inflammable should be permitted in their construction. The other item to consider is an accident to the boilers, causing a serious explosion. This, again, is not likely to happen where first-class supervision and a good water supply can be obtained; but is more likely to happen where a number of works, without sufficient supervision, are established. In fact, too much consideration cannot be given to the selection of the site, as, to a large extent, the whole question of successful working—both financially and from an engineering point of view—hinges on it. In selecting the site, it is therefore advisable: (1) to obtain a good water supply to enable condensing operations to be carried out cheaply, and without a great deal of auxiliary machinery; (2) the facilities for obtaining coal at the cheapest possible rate, either sea or rail borne; (3) the site should be chosen where the works are likely to be the least nuisance to surrounding property; (4) facilities should be obtained for getting goods of a heavy nature; (5) provision should be made for future extensions, without having to buy up surrounding property; (6) the nearest point to the centre of the demand which complies with the above conditions should be selected, although it is not difficult to transmit electric power to large distances economically.

In the case of large works, it is very convenient to find accommodation in or near the site for the principal workmen employed; as should anything go wrong with the machinery, necessitating a temporary extinction of the lights, the men can be easily fetched. This especially applies to the mains superintendent, who should always be accessible, and for this purpose it is often found advisable to buy up the surrounding cottage property, or build cottages for the men.

The employment of "experts" to advise is rather a

* Abstract of paper read before the British Association at Bradford.

† Paper read before the Incorporated Association of Municipal and County Engineers, at a meeting held at Tonbridge and Deal, on Sept. 14 and 15.

vexed question, but for towns to commence operations without having the advantage of expert advice is suicidal, as a mistake made in the selection of site will prove fatal to the undertaking, and unless a town can afford to pay an adequate salary to a first-class resident engineer who is competent to advise them, it is advisable for them to obtain a report, and carry out the work under instructions of the practical expert, appointing a resident engineer to act under him; and the author suggests that a good practical expert, who is or has been employed in similar practical work, should be called in to advise on the selection of the site, the policy to be adopted, and the system used, afterwards engaging a resident manager to look after the commercial and technical sides of the undertaking, retaining the consulting expert, either by means of a percentage, or paying him an annual retaining fee. This arrangement enables small towns to obtain expert advice at a minimum expense. The advantages of starting works in small towns is greater than that in large, because large towns usually possess sufficient industries to find employment, whereas in a small town it creates an entirely new industry, gives employment to many men, and improves the town from a sanitary point of view, and where public lighting is undertaken provides a means of decreasing crime.

Small Works.

It is impossible to find a man willing to accept a small salary and be capable of advising on all the intricate questions met with in the maintenance and construction of an undertaking, which, though it may be small in size, has the same principles involved as that of a large undertaking. Many towns have started, or are contemplating starting, dust-destructor works in combination with electricity works, and there is no doubt that from the figures recently obtained from the various combined works throughout the country a considerable saving in fuel is effected by burning refuse, and it has been found that in the latest type of destructors 1lb. of refuse will evaporate ·79lb. of water from, and at 212deg. F. Shoreditch was one of the first works put down, and has been able to produce exceedingly low fuel consumption figures compared with other electricity works. However, a refuse destructor should be designed to fulfil the following conditions: (1) it must not be a nuisance to the surrounding neighbourhood; (2) there must be very little smoke issuing from the shaft; (3) there must be no dust scattered about or taken up the chimney shaft; (4) the destruction of the refuse must be complete; (5) it must be capable of raising high-pressure steam in sufficient quantity to be able to utilise it for commercial purposes.

It has been found from experience that the refuse in watering places is worth nearly five tons of Welsh steam coal per 35,000 inhabitants per day. I have been able to make a careful inspection of the working of the Llandudno dust destructor during a short stay in that town, which is built on the Beaman and Deas principle, with Babcock and Wilcox boilers. I do not consider that this destructor complies with the conditions necessary, although as an economical steam generator it has proved a very big success, and the figures arrived at in fuel by the Llandudno electricity works of something under ½d. per Board of Trade unit generated is much below the average for a similar undertaking. These results are better than were ever anticipated. However, the principal difficulty appears to be that when one is 100 yards away from the works, in the windward direction, a considerable smell exists. Another disadvantage is that during the time the refuse is being destroyed white or brown smoke issues from the shaft, which smoke is a nuisance to the surrounding property. So far as the other advantages are concerned, this destructor fulfils them absolutely. No doubt there are many members present who are more competent to speak and to give us their opinions on the subject than the author, and it will be interesting to hear their remarks upon the same, as everybody must be agreed that the only way of dealing with refuse in a sanitary manner is to cremate it. A very interesting paper was read before the Institution of Civil Engineers (in which the author took part in the discussion) by Mr. Charles Russell, electrical engineer of Shoreditch, in which he deals minutely with the troubles and difficulties and the value of dust-destructor plant. In the *Proceedings* he gives a curve showing the actual amount of work done by the refuse and the amount of coal burnt, also a curve showing the available steam pressure. Of course, the value of the residue for roadmaking and builder's purposes is an item which is worthy of consideration, and from Mr. Russell's paper I cull the following percentages of which the residue is composed:

	Per cent.
Common clinker	29·0
Fine ash	2·7
Fine dust	0·5
Old tins	0·6
Total	32·8 per cent.

There is a tendency on the part of most destructors to emit from the shaft particles of fine dust. However, several of the contractors have endeavoured to obviate this difficulty by "dust catchers," which can be readily cleaned out. Another use for the residue is the making of artificial paving stones, and I believe I am right in saying Shoreditch uses these stones very largely. The labour item is a very important one, as at Shoreditch it works at 2s. 6d., at Llandudno 1s. 4d., and Hereford 1s. 1d. The most satisfactory way of running refuse-destructor works in combination with electricity works is to have some of the boilers arranged for hand firing with coal, so that these boilers can act as a reservoir of steam and assist in steadying the general steam pressure throughout.

The capital outlay for the establishment of electricity works varies to a large extent with the local circumstances, and if a consulting engineer be employed to draw up a scheme he will, no doubt, give the capital outlay required to carry out this scheme in the report. However, it must not be forgotten that since the loans to corporations in the provinces are only granted for 25 years, every £100 saved in the capital outlay represents £6 less to be charged against the revenue account for interest and redemption fund. There are many methods by which corporations can raise money for this purpose. It is, however, always necessary to obtain the sanction of the Local Government Board for the requisite loan, after which stock may be issued or any of the well-known financial arrangements entered into. Precautions should be taken that the corporation does not borrow the capital before it can be actively employed, or, in other words, produce a return. A rough idea of the amount of capital required is given in the following table:

Number of lamps in 8 c.p. or their equivalent. Lamps.	Approximate capital outlay required. £
2,000	8,000
5,000	12,000
10,000	20,000
20,000	35,000
40,000	69,000
100,000	170,000

In selecting a site, consideration must be given to the system by which it is proposed to supply the town, whether high or low pressure. Should it be proposed to generate high-pressure currents at the works, it will not matter if the site be chosen outside the area of supply, but should the town lend itself to a low-pressure system, then the site must be chosen as near as possible to the centre of the demand, otherwise useless expenditure will be incurred on heavy copper feeders.

In the early days there was great diversity of opinion possessed by experts as to which was the best system to supply, and there is no doubt that what might be the right system for one town is not necessarily so for another, as both systems have their respective disadvantages. Large scattered areas can only be supplied by high tension, whereas towns of a compact nature can be more cheaply supplied with low tension. For those members who are not familiar with the technical expression "high" and "low tension" the author submits the following explanation: Electricity is simply a form of energy existing in nature, which requires special machinery to set it in motion—the same way, as in coal, there is no energy or life until it is burning. The measurement of electricity is composed of two factors. The product of the factors when multiplied

Digitized by Google

together are termed "watts." Either factor may be altered, and yet the amount of energy would remain the same. For instance, one unit of current, called the "ampere," multiplied by 100 units of pressure, called the "volts," equals the energy which would be 100; or it would equal 100 units of current multiplied by one unit of pressure. In the former case you might call it high pressure; in the latter you might call it low pressure, except for simplicity sake the Board of Trade have stated that anything over 500 volts must be considered as high pressure. The systems are: (1) the high-pressure alternating-current system; (2) the high-pressure continuous-current system; (3) the low-pressure continuous-current system; (4) the low-pressure alternating-current system. But the principal ones adopted are: (1) the high-pressure, and (3) the low-pressure continuous-current—in fact, all the schemes are based on these.

There are at the present moment no less than 112 electricity works in operation owned by local authorities, and 94 companies. There are 81 local authorities who have decided to establish electricity works at once, and there are no less than 115 provisional orders granted to local authorities, but works not yet finally decided upon. From the financial results of the undertakings which have been working for more than one year, ample proof can be found that, if well managed, they can be a financial success. It must not be forgotten, however, that many of the undertakings that show deficits, are in reality buying their works on what might be termed "the easy payment system"—that is to say, in 25 or 42 years, as the case may be, the works will become the property of the general ratepayers—having been bought by the consumers by setting aside so much per annum before declaring a net profit, keeping the works in thorough repair all the time.

The distribution from the works may be effected by several means, but the latest practice for low tension is to lay three conductors side by side in the same trench of the following types: (1) Bare conductors carried on insulators in concrete or iron conduits. This system is being superseded now on account of the increase in the pressure of supply to consumers. (2) Three insulated single conductors laid in troughs, and run up solid with some suitable material. (3) Concentric cables, armoured, and laid directly in the ground, with bricks or timber to protect them from picks. (4) Single cables drawn into stoneware conduits. (5) Three-core armoured cable laid directly in the ground.

For distribution by alternating currents the system most used is the armoured concentric cable, laid directly in the ground or in troughs, run in some hard compound, in which case it is not necessary for the cable to be armoured. This forms a cheap means of laying cable, besides being very durable. There are, of course, a number of different means by which the energy can be regulated from sub-stations, but in this paper there is no time to deal with them. With regard to the overhead system, which is unfavourably entertained by the Board of Trade, the author believes that in the future we shall see more use made of this for transmission of high-pressure currents to long distances, for the lighting purposes of country villages, and for farming industrial purposes, as there is no donbt that high-pressure energy can be transmitted perfectly safely, the same as is done in Switzerland and other countries on a large scale. The water proposed to be used should be carefully analysed before a decision is come to with respect to its suitability. If possible, it should be obtained simply for the cost of pumping—that is to say, a well should be sunk and ample supply be obtained at a figure not exceeding 6d. per 1,000 gallons. There should, of course, be an independent supply from the town mains in the event of a spring failing in the very dry weather. In making arrangements for the water supply, it is important that due regard should be given to the extensions and the heavy demand that will be required at a future date; it is not enough to arrange for a sufficient amount of water for two years, but the quantity should be at least trebled in making calculations. If the works are situated near a river or canal care must be taken with the foundations, as any settling will cause serious trouble with hot bearings, leaky joints, etc. The Tunbridge Wells water for steam-raising purposes is extremely troublesome water to deal with. Its corrosive properties are very high, and it may be interesting to give you the analysis of the water used:

Well Water.	Grains per gallon.
Calcium carbonate	·70
Calcium sulphate	7·43
Sodium chloride	5·61
Oxide of iron	·81
Nitrates and nitrites of lime and magnesia	3·95
Total	18·50

Town Water.	Grains per gallon.
Calcium carbonate	1·75
Calcium sulphate	·53
Magnesium sulphate	·72
Magnesium nitrate	·90
Sodium chloride	2·64
Total	6·54

Of course, one of the most successful treatments for the purification of water is that known as the "Archbutt-Deeley" process, by which the carbonates of lime, or calcium carbonate, can be got rid of, and the hardness reduced to something under 4 per cent. It will be noticed from the analysis of the waters given above that the carbonates are low and the sulphate high, and it has been found from experience that calcium sulphite is one of the most objectionable constituents of boiler water on account of the hard scale it produces. Mr. Archbutt read an excellent paper before the Institution of Mechanical Engineers on the subject of "The Softening of Water," in which he shows clearly that certain classes of water do not render themselves amenable to treatment, and in most cases the source has to be given up and a fresh one sought after. This water difficulty has affected the costs in Tunbridge Wells considerably, and it is only those who are familiar with steam raising when using good and bad water who can appreciate what trouble bad water will give.

In Tunbridge Wells the cables are armoured, concentric, lead-covered, laid direct in the earth with bricks over them to protect them from mechanical damage. The insulation is paper, and they have now been laid some six years, and have been found to be exceedingly satisfactory. Tunbridge Wells is a very scattered area to deal with, and there are no less than 100 yards of cable laid per consumer. The total length of cables laid in Tunbridge Wells amount to 41¾ miles. The author has found it necessary (owing to the damage done to the cable by contractors breaking the surface of the roads for the purpose of water, sewer, and other surfaces) to require that contractors, before disturbing the surface, must give notice of their intention of so doing in order to enable a representative to be sent to indicate the position of the main, and see that care is taken when crossing or exposing the cable. Since this system has been in vogue, not one cable has been damaged. All the cables have been laid by the Corporation's own men, under the author's supervision.

Price.

The question of price charged for electricity must depend upon the cost of production, which cost of production is made up of the capital outlay, the works costs, and other items. In Tunbridge Wells the price charged is based on the maximum demand system. For the first hour's supply the price is 6d.; for units consumed over and above this the price is 3d., from which it will be seen that consumers who burn their supply for one hour per day per annum pay 6d. per unit. Consumers that burn it on an average of two hours per day per annum, pay 4½d. per unit; three hours per day per annum, pay 4d. per unit.

Method of Charging for Electricity.

Engineers are agreed that that there is only one fair and equitable way of charging for electricity, based on the "maximum demand system." The cost of production is made up as follows: (1) fuel; (2) water; (3) oil, waste, and petty stores; (4) salaries and wages; (5) repairs and maintenance; (6) rents, rates, and taxes; (7) sinking or redemption fund; (8) interest on the capital; (9) depreciation; (10) contingencies. Items 1, 2, and 3 increase in proportion to the number of units generated—that is to say, if four times the number of units are turned out, items 1, 2, and 3 will be nearly four times as much. This is not the case with items 4 to 10; it would be possible for us to turn out four or five times as much energy without

Digitized by Google

increasing these items at all, provided the maximum demand was not greater. The financial value of the above may be taken as follows:

	Per unit.
Coal, oil, water, and waste cost	1·03d.
Salaries, repairs, sinking fund, interest, and depreciation	6·00d.
Total cost of production for first hour, per unit sold...	7·03d.

Now, it is clear from the above that if a consumer burns his lamps for more than one hour per day, the extra additional cost to us will only be 1·03d. per unit; and, again, the same applies if he goes on burning it for a large number of hours. Take, for instance, an hotel consuming, on an average, its maximum demand for five hours a day; the total cost of supplying energy to this hotel per unit would be one hour 7·03d., plus four times the cost of oil, coal, water, and waste, divided by 5, which equals 2·23d., arrived at as follows:

Cost of supply—first hour	7·03d.
,, ,, second hour	1·03d.
,, ,, third hour	1·03d.
,, ,, fourth hour	1·03d.
,, ,, fifth hour	1·03d.
	11·15d.

Average cost per hour $\frac{11 \cdot 15}{5} = 2 \cdot 23$d. per unit.

It is for this reason that it has become almost a universal practice to charge on the maximum-demand system, because it is a system which endeavours to obtain an equal rate of profit from all consumers, and does not place the best consumers—*i.e.*, hotels, public-houses, and clubs—at an unfair advantage to the consumer who burns his lights for only a short period. It will be seen that we are actually losing money on the consumer that only burns his lights for 365 hours per annum, and that loss has to be made up out of the profits obtained from the paying consumer. In order to establish a successful electricity undertaking every encouragement should be given to those consumers who burn their lights a large number of hours, even if it means the discouragement of the consumer that would be a loss to the works. A uniform charge can never be so low as the average price charged on this system, because a uniform price encourages people to burn their lamps only for a short time, and that uniform price would be too expensive for the best customers, such as hotels, public-houses, clubs, etc., to adopt electricity as an illuminant. Short-hour consumers do not care for this method of charging, and they would prefer a uniform price, where the loss caused to the works by having them on the mains would be paid out of the profits that would be obtained from the profitable class of consumer. Unfortunately, however, experience proves that this good class of consumer finds a uniform price too expensive, and eventually gives up the illuminant, not caring to pay for the losses caused by other consumers. A great point in favour of this system is that the rate of profit is uniform for all classes.

The instrument used for ascertaining the maximum of each consumer consists of a hermetically-sealed tube, containing air and a liquid, a conductor of short length and a slightly higher resistance than copper. Current passing through the conductor causes a slight generation of heat, which expands the air inside the tube, and forces a portion of the liquid up to the tube adjoining, where it remains permanently, until it is reset by the meter inspector. The amount of liquid forced up the tube is proportionate to the consumer's maximum demand, or in other words, "the capital outlay that consumer has put the electricity undertaking to, to supply him." There is no mechanism to get out of order, nor can their accuracy be doubted.

There are certain laws which govern the principle of trading successfully: (1) All consumers should be a source of profit. (2) The tariff should provide an equal rate of profit from all consumers. (3) It is sound commercial practice to encourage the profitable, even at the risk of losing the unprofitable. (4) The cost of supplying electricity depends upon the length of time the necessary plant and mains to supply the maximum demand are used. (5) It is only by adopting a correct sliding scale, in direct proportion to the costs, that it is possible to make the tariff sufficiently low to reach the many. (6) The uniform rate usually means that a consumer pays two lighting bills. He instals electricity in his shop windows, and in the places where the light is only burnt for a short time per day, and refuses to put it in such places as cellars, basements, etc., where it is burnt for many hours, because he looks upon it as a luxury. It is this habit which the sliding scale system corrects, because electricity is only installed in corridors, kitchens, bedrooms, workrooms, etc., if it is cheaper than gas, and competition must simply be based upon the cost. (7) The conditions of gas and electricity production are essentially different. In the case of gas, its cost per 1,000 cubic feet delivered does not bear any relationship to the maximum, or the number of hours, because gas is never delivered direct, but stored in gasometers.

There is perhaps no business in which capital is employed for so small a number of hours as that of electricity supply, and we ought to do everything within our power to stimulate the large number of hours of demand. In our own undertaking we have expended the sum of £40,000 approximately, which sum has to earn sufficient revenue to pay all the expenses in 1,460 hours per annum, whereas had the consumers been burning the light evenly all through, we could have employed it profitably for 8,760 hours.

Four hours per day per annum pay 3¾d. per unit.
Five ,, ,, ,, 3¼d. ,,

It is interesting to note the relative prices obtained from various classes of consumers in Tunbridge Wells:

Public-houses and hotels—average price paid for electricity	3·9d.
Shops	4·8d.
Private houses	4·89d.
Offices (early closing)	6·00d.
Churches	6·00d.

From which it will be seen that the public-houses and hotels obtain their supply at an exceedingly low rate, and far cheaper than they could ever hope to generate it themselves.

There are many ways of charging for electricity: (1) sliding scale, giving long-hour consumers the lowest rate; (2) uniform price; (3) percentage rebate on the amount consumed; (4) percentage rebate on the number of units consumed per lamp. There are, however, only two of these systems worthy of consideration—viz., the uniform price and the long-hour consumer rate.

The works should be organised into various departments: (1) the meter department; (2) the distribution department; (3) works department; (4) public lighting department; (5) the clerical department. Each department should have a responsible official, who, again, should be responsible to the chief engineer. Of course, this is not easy to arrange in small towns of less than 30,000 inhabitants, but where it can be done greater efficiency and satisfaction is given.

Power.

In manufacturing towns it pays to develop a motor load—that is to say, that electricity forms one of the best and cheapest methods by which power supply can be given at a reasonable rate, and in Bradford this question of power supply has been largely developed, there being no less than 411 motors on the Corporation mains, and the units sold to these motors are 463,630 per annum. They are used for every industrial purpose, and a very interesting description of the motors in use is given in Mr. Gibbings's book (section 4), "Electric Motive Power." It is, of course, equally important that the power supply should be developed in small towns as well as large, although in residential and pleasure-seeking towns there cannot be much demand. The price charged for the motor supply should be low, as the energy is used during the daytime, when it is not required for lighting purposes, and otherwise the plant at the works would be standing idle, so that it pays to supply the energy at a rate lower than that charged for lighting, especially as the motor load is a long-hour one.

There are few towns of over 30,000 inhabitants that are not considering the question of establishing tramways, and, especially in residential towns, considerable opposition is experienced; but it must not be forgotten the advantages of tramways are very great: (1) tramways conduce to rapid transit from place to place, thus improving the prosperity of the town; (2) tramways are found by expe-

Digitized by Google

rience to increase trade along the line of route; (3) tramways form the solution to the "housing of the masses"; (4) a tramway may be called the "people's carriage"; (5) in the near future, tramways will play an important part in the conveyance of merchandise, and will become severe competitors with the railway companies; (6) tramways are the only means by which cheap fares and rapid transit can be provided; (7) tramways mean starting another industry in the town that benefits the community in general.

There are, however, objections which may be summed up as follows: (1) tramways convert residential districts into business ones; (2) the unsightly overhead trolley system must be weighed against the advantages gained; (3) the noise along the route; (4) tramways tend to drive carriage people away.

It is, of course, a well-accepted fact that the only means to propel tramways is by electric energy: (1) on account of the working expenses—*i.e.*, the low cost per car mile; (2) the ease, comfort, and speed in travelling; (3) on account of the easy surmounting of heavy gradients; (4) on account of the freedom from wear and tear on the roads: (*a*) fouling the streets; (*b*) absence of noise; (*c*) the freedom from accidents.

It will be seen from the opinion expressed above that, where possible, the lighting and tramway works for the generation of electricity should be under one roof and one management, as only by that means can the full benefits of the combination be obtained. The plant which is available at night-time for supplying energy for lighting purposes, in the daytime will be available for running the cars, and during the hours of lapping load it might be advisable in the case of small towns to "horse" the tramways, or have sufficient storage capacity to cope with the demand. There is no doubt that works can be put down at a much cheaper rate per kilowatt than they would be if the works were separated, as the machinery in the case of the lighting works would only be used a very few hours per day, whereas if it were used for both purposes it would be almost in continual use, and the load factor would be improved.

Most of the members no doubt are aware, and have studied the question of tramways for their own respective towns, and I need only refer them to the very successful system in operation at Dover to show what can be done on a small scale. Space or time does not permit going into details of construction for tramways in this paper, but an account of same can be obtained in the author's fourth year's report, which contains in the appendix a copy of the tramway report presented to the committee, in which are given details, such as the weight of rails, the relative merits of the different systems, the construction of the permanent way, the overhead gear, feeders, gradients, working expenses, etc.

Public Lighting.

It is important for towns undertaking electricity supply to commence with a thorough system of public lighting, and to light the whole of the district either by arc or incandescent electric lamps along the line of route in which the cables are laid, and the author advocates the policy of laying the mains well in advance of the demand; this especially applies to small towns, where it has been found that consumers will not come on until they see the actual cable laid, and the policy of extensions may be considered the only speculative part of the business, as it is useless having the works too large with a great deal of idle plant, and the mains only laid in a few streets. The author has introduced a system of reflectors, by which he obtains far greater efficiency out of an ordinary lamp for street-lighting purposes, and commends it to the notice of the members of this association. It can be seen in operation, lighting many of the streets of Tunbridge Wells. The Council have decided to erect 262 additional ones. In this paper the author has purposely refrained from giving a detailed description of the Tunbridge Wells electricity works, as he hopes to have the honour of showing the members of this association round, when they will see for themselves what has been done, and he hopes the paper will prove a valuable contribution and promote a good discussion at the association's meeting.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

Questions.

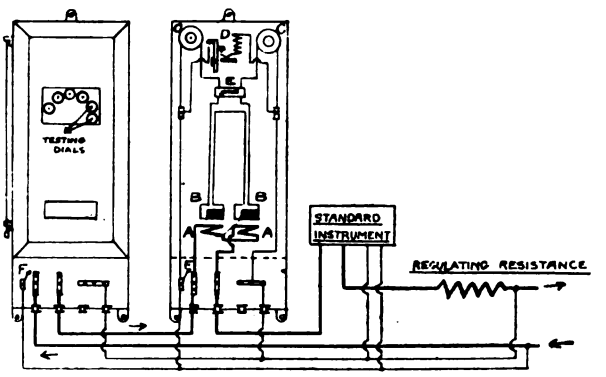
311. What is the advantage gained by setting the cranks of small compound vertical engines at angles other than 90deg.—for instance, about 145deg. ?—F. H. P.

312. Having a ring armature (laminated), 9½in. outside diameter, 5in. inside diameter, and 3¼in. deep, I wish to wind same as a step-down transformer for use on a 100-volt 60-cycle circuit so as to yield 40 volts from secondary at its maximum capacity. What size of wire and number of turns will be required on primary and secondary? Would it be possible to subdivide secondary circuit so as to yield various voltages ?—C. L.

Answers.

Question No. 305.—Explain how to test the Aron new model watt-hour meters for alternating current at ordinary periodicity, if possible, with direct current.

Answer to No. 305 (*awarded* 7*s.* 6d.).—The new type Aron self-winding watt-hour meter consists of two series coils, A A, through which the main current passes, and two pressure coils, B B, connected in series, and in series with which are two supplementary non-inductive resistances, C C. E is the commutator for reversing the direction of the current through the coils, B B. D is the self-winding



arrangement. The internal connections of the meter can be plainly seen in the sketch. As the action of the meter depends upon the difference in the oscillations of the two pendulums, a short test cannot be taken as with meters with a revolving disc. It will be advisable first to consider the principle of the action of this meter. When the meter is put on circuit, the meter is immediately wound up, and the pendulums begin oscillating. When current passes through the series coil, it causes one pendulum to be accelerated and the other retarded; the difference between these oscillations is recorded by very accurate mechanism, which works in conjunction with the time-keeping arrangement, so that a very accurate watt-hour meter is the result. When the meter is running on an open circuit, the two pendulums should theoretically swing in synchronism, but in practice this is found to be impossible. To overcome this difficulty the current is reversed every 20 minutes* through the pendulums, by means of which the error caused by want of natural synchronism is eliminated. It is obvious, then, that no test which covers a period of less than 20 minutes can in any way be considered a test. To take a very accurate test, it should be taken throughout the entire range on the basis that the full-load test occupies three complete

* We believe that 10 minutes is the interval, so that 20 minutes represents the complete cycle.—Ed. *E. E.*

Digitized by Google

cycles of the reversing apparatus, and the lower the load the longer the test. For example, a test with a quarter load should occupy four hours, and so on throughout the range.

It is advisable to test the meters in batches, and take a test on the face dial. Two dials (coloured red) are provided for this purpose, one reading in ·01 unit and the other ·1 unit; pointers are supplied by the makers, and can be affixed for testing. The meters should be hung perfectly perpendicular; a plumb bob is provided at the side of the meter to enable this to be done. The meters should be connected up according to the diagram, the shunt connection at F being broken. This the writer failed to do, and found that No. 1 meter read correctly, No. 2 read correctly plus shunt current of No. 1, No. 3 the same plus shunt current of Nos. 1 and 2, and so on. The best instrument for testing watt-hour meters is the Kelvin watt-balance, which can be used for both alternating and direct current, a useful size being the one with a range from about 0 2 to 120 amperes, which is provided with a box of resistances to put in series with the movable or shunt coil, so that it may be used on a 50, 100, or 200 volt circuit. A non-inductive regulating resistance is also required for varying the load, and a fly-back centre second chronograph for accurate work. First adjust to the load that is required, switch off, take readings of the meter, then switch on, keeping the watts constant at the specified load for at least 40 minutes, entirely open the circuit, and again take readings. It is known what has exactly passed through the meter, so that the percentage error is easily obtained. ("The above method of testing is for alternating current; the meter could not be used on direct current, as the winding arrangement would require to be rewound. By disconnecting the winding gear circuit and driving it by a separate alternating current, the meters could then be tested with direct current. The registration alone is constant for both alternating and direct current. This also applies to periodicity, as the winding gear has to be wound to suit the periods.") The meter will register the smallest fraction of a watt, and it has been found to register the leakage on an installation. Consumers have to be assured that the meter is not recording anything, even if they can hear it ticking, when no lamps are in use.—W. A. J.

Answer to No. 305 (*awarded 7s. 6d.*).—The alternating-current type of the new type Aron watt-hour meter can be tested quite as well on continuous as on alternating current, but the precaution should be taken of connecting the winding circuit to the alternating mains, as if continuous current of the full voltage were put on this circuit, it would probably be burnt out. To test these meters satisfactorily it is necessary to have a small testing battery of storage cells (of, say, five or six ampere-hours capacity) from which the pendulum circuit may be excited. Of course, we may use the ordinary lighting circuit for this purpose; but it will be found almost impossible to get steady enough volts. The shunt circuit must first of all be split and the pendulum circuit connected through a suitable adjusting resistance to the testing battery, and the correct voltage got across the terminals; the winding circuit must then be connected to the alternating mains. There is no necessity to measure the volts on this part during the test. Having got the shunt circuits alive, it now remains to run the various currents through the main coil and take the advance on the meter, at, say, full load, three-quarter load, half load, quarter load, and one-eighth load, running each load long enough to give a fair advance. It will be found advisable to have an advance of at least one unit at one-eighth load, as, owing to the amount of back-lash in the gearing, it is rather difficult to read the meter very closely, and the larger the advance the smaller this error becomes. Readings should be taken of the current in the main and the volts on the pendulum at intervals of five minutes during each test so that a true mean can be got.

The following full-load test of a 50-ampere meter will show the method of calculating the constant from the figures obtained as above:

Mean current = 49·28 amperes; time = 20 minutes; mean volts on pendulum = 200·15; advance on meter = 3·33 units.

Actual units passed through meter

$$= \frac{200{\cdot}15 \times 49{\cdot}28 \times 20}{60 \times 1{,}000} = 3{\cdot}287.$$

∴ Constant for units at full load

$$= \frac{3\,287}{3{\cdot}33} = {\cdot}987.$$

The constant is worked out for each load and the mean taken, which gives us the working constant for the meter. Of course, if no testing battery is available for the pendulums, the shunt circuit, as a whole, may be run off the usual lighting circuit.—ELECTRICIAN.

Question No. 306.—When running a dynamo and cells in parallel, if the voltage of both are the same, the current will be equally divided. Now, if the voltage of the cells drops one-eighth of a volt, will the whole of the current be supplied from the dynamo, presuming its capacity to be great enough and its regulating qualities perfect?

Best Answer to No. 306 (*awarded* 10*s.*).—To answer this question fully, exception must be taken to the statement which prefaces it. As a matter of fact, the current in such a case is not divided equally between the dynamo and battery, but inversely to their respective resistances, as the following equation will plainly show. Let C_1 and C_2 be the respective currents, R_1 and R_2 the resistances of the dynamo and battery, and E the voltage of both (it is assumed that in the statement the E.M.F.'s are taken to be equal "on open circuit," as they must of necessity be equal when both sources are joined to the same pair of 'bus bars); then on closed circuit

$$E - C_1 R_1 = E - C_2 R_2,$$

from which we get $C_1 = \frac{C_2 R_2}{R_1}$.

It will be noticed that if R_1 of the dynamo be smaller than R_2 of the battery, then, to satisfy the equation, C_1 must be proportionately greater than C_2. If the voltages on open circuit are unequal, then, on closed circuit,

$$E_1 - C_1 R_1 = E_2 - C_2 R_2,$$

from which we get

$$C_1 = \frac{(E_1 - E_2) + C_2 R_2}{R_1}$$

Dealing with the question proper, the dynamo will not supply the whole of the current were the battery voltage to fall slightly or by ·125 volt, for the simple reason that the armature possesses resistance. What really happens in this case is that the dynamo will supply a little more and the battery a little less, the amount of increase in the dynamo being such that it will bring down its voltage to that of the decreased battery E.M.F. A numerical example will demonstrate the action more clearly. Let the letters have the same significance as before, and the terminals of the dynamo and battery be connected to the same 'bus bars feeding a circuit possessing a resistance of four ohms, R_3, and let the E.M.F. of both be 100 volts on open circuit, the resistance of the armature (including brushes, etc.), be ·11 ohm, and the battery resistance ·3 ohm.

Then $E - C_1 R_1 = R_3 (C_1 + C_2)$ . . . (1)

also $E - C_2 R_2 = R_3 (C_1 + C_2)$ . . . (2)

$$\therefore C_1 R_1 = C_2 R_2.$$

Substituting values, we have

$$C_1 \times {\cdot}11 = C_2 \times {\cdot}3.$$

$$\therefore C_1 = 2\,7272\ C_2 \quad . \ . \ . \ . \ (3)$$

Applying (3) to (1)—

$$100 - (2{\cdot}7272\ C_2 \times {\cdot}11) = 4\ (2\,7272\ C_2 + C_2)$$

from which $100 = 15{\cdot}2087\ C_2$

$$\therefore C_2 = 6{\cdot}575 \text{ amperes}$$

and from (3) $C_1 = 17\,931$,,

Total output... 24·506 ,,

Voltage across 'bus bars = 98 024 volts.

Considering now the case when the battery E.M.F. drops ·125 volt, and using the same formula, but with the altered quantity in (5), we have

Digitized by Google

$$100 - \cdot 11\ C_1 = 4\ (C_1 + C_2) \quad . \quad . \quad . \quad (4)$$

and $$99 \cdot 875 - \cdot 3\ C_2 = 4\ (C_1 + C_2) \quad . \quad . \quad . \quad (5)$$

$$\therefore 100 - \cdot 11\ C_1 = 99\ 875 - \cdot 3\ C_2$$

from which $$C_1 = \frac{\cdot 125 + \cdot 3\ C_2}{\cdot 11}$$

$$= 2\ 7272\ C_2 + 1 \cdot 136 \quad . \quad . \quad . \quad . \quad (6)$$

Applying (6) to (4)—

$$100 - (2 \cdot 7272\ C_2 + 1 \cdot 136)\ \cdot 11 = 4\ (2 \cdot 7272\ C_2 + 1 \cdot 136 + C_2)$$

$$100 - \cdot 3\ C_2 - \cdot 125 - 4 \cdot 544 = 10\ 9088\ C_2 + 4\ C_2,$$

and $$95 \cdot 351 = 15 \cdot 2087\ C_2$$

$$\therefore C_2 = 6 \cdot 269 \text{ amperes,}$$

and from (6) $C_1 = 18 \cdot 232$ „

Total output... 24·501 „

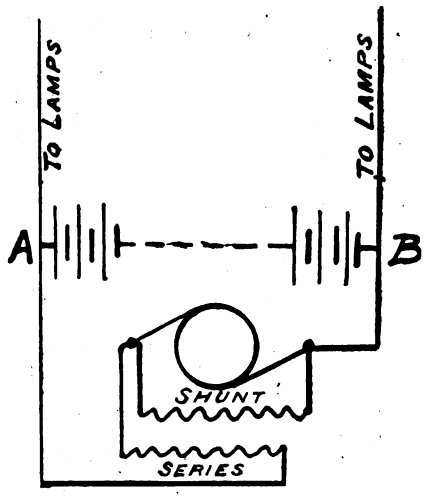
Voltage across 'bus bars, 98·004 volts.

The dynamo current, C_1, has slightly increased, and that of the battery, C_2, decreased. This is what generally happens in an installation with accumulators, the dynamo being kept at constant voltage, and the battery current gradually decreasing as discharge goes on until a balance is effected, when no current is given by the battery, such as is obtained with the potentiometer. At this stage of balance the E.M.F. of the battery equals that of the dynamo, minus the armature drop. Applying, again, the formula with $C_2 = 0$, it will be found that in order to obtain this balance the battery E.M.F. has to fall to 97·32 volts, thus conforming to the conditions in the question.

It will be noticed that in the second case, although we have taken ·125 volt as the decrease (on open circuit), the difference in the ultimate voltages across the 'bus bars is only ·02 volt. This is accounted for by the smaller current given by the battery, consequently a smaller drop.—E. J. EVANS.

Answer to No. 306 (*awarded* 5*s.*).—The first statement in the question is true only if the internal resistances of dynamo and battery are about the same. In any case, if the battery is giving current, its E.M.F. must be equal to the volts between the mains, together with the volts lost in the battery (C R). When the E.M.F. falls the result will be that the current from the battery will diminish slightly, and the lost volts will thus be reduced. The volts lost in a battery at full load are something like 1 or 2 per cent. of the total volts, and when the E.M.F. is reduced by this amount the battery current will fall to zero, and the whole load current will be supplied by the dynamo. Any further reduction in the E.M.F. will cause a current to flow from the mains, tending to charge the battery, but, unless the E M.F. is much reduced, the current will not be large, since it is opposed by the back E.M.F. of the battery. It should be noted that the E.M.F. of a battery depends to some extent on the magnitude of the current, and also on the direction of the current—*i e*, whether charging or discharging. If a discharging current is increased the E.M.F. falls, while if a charging current is increased the back E.M.F. rises. This action, it will be seen, acts to some extent as an automatic regulator on a battery used in parallel with a dynamo, and it explains why switching in, say, one extra cell does not raise the voltage on the mains by anything like two volts.—W. E.

Answer to No. 306 (*awarded* 5*s.*).—The question tells us that the regulation of the dynamo is perfect, and, referring to the figure, I take this to mean that the potential difference between A and B is constant at all loads. It is also stated that if the voltage of the dynamo equals that of the cells, the load is equally divided between them. Now this is a very vague and misleading statement. Does it mean that the voltages at the terminals of each are equal on open circuit? For if so, the load will certainly not be equally divided when current is running, because the dynamo is compensated for pressure loss due to the current, and the cells are not. Under these circumstances the battery would be just neutral, neither giving nor receiving current. Yet what else can the statement mean, for when connected up as in figure, A and B are, practically speaking, common terminals of both dynamo and battery, and one cannot imagine these points having one potential difference with respect to the dynamo and another due to the battery. One of the elementary laws of the electric circuit is that if current is flowing through a conductor of any kind, whether liquid or solid, a certain loss of pressure results from overcoming the resistance of the conductor, and this loss is proportioned to the current



passing. Consequently, apart from regulation, the voltage at the terminals of both cells and dynamo would be largely dependent upon the current flowing, if each were running upon a separate circuit. They are not running separately, however, but in parallel, and, moreover, the dynamo is automatically compensated against a drop in voltage. It is evident, therefore, that the battery must accommodate itself to circumstances. This it does by allowing just such a current to pass as would cause a voltage drop at its terminals equal to the difference between its open circuit voltage and the constant potential difference between A and B.

If V = potential difference between A and B;
v = open circuit voltage of cells;
b = internal resistance of cells × leads between A and B;
C = current flowing from the cells;

$$V = v - b \times C, \text{ or } C = \frac{v - V}{b}.$$

Referring directly to the question: if, when the cells are in a certain condition, and the load upon the external circuit is such that an equal current flows from dynamo and battery, then any depreciation in the cells will be followed by a drop in the current given out by them of just such an amount as would cause a pressure loss equal to the depreciation, if overcoming the internal resistance of battery + leads between A and B.—W. G. MURRIN.

Answer to No. 306 (*awarded* 5*s.*).—If we assume that not only the dynamo, but also the cells, have perfect regulating qualities—*i.e.*, give exactly constant volts at all currents—the smallest drop in cell voltage relatively to the dynamo voltage would not only transfer all the external load to the dynamo, but would also cause a charging current to pass from the dynamo into the cells until the two voltages were made equal again. Such a combination would, in fact, not be workable. In practice, of course, the curve of battery voltage is not an absolutely level line, but droops as the load increases. This is due to the resistance of the electrolyte and of the connections from cell to cell, which causes an increasing ohmic drop with increased current. Should the battery voltage when working at a certain current drop, therefore, as suggested in the question, the result would be that the amount of current given by it into the external circuit would merely fall off until a point on the discharge voltage curve was reached at which the battery voltage was again equal to the dynamo voltage, when a steady state would have again been obtained. At the same time, the dynamo current, assuming it a perfectly self-regulating machine, would increase by the same amount as that by which the battery current is diminished.—Q.

OLDHAM ELECTRICITY ACCOUNTS.

The following is the report of Mr. Arthur Andrew, superintendent, on the working of the Oldham electric light station for the year ended March 24, 1900, together with abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc. :

The expenditure on capital account during the year has been as follows: Supply station—buildings and plant, £4,380. 7s. 11d.; street mains, £4,933. 17s. 6d.—total, £9,314. 5s. 5d. The gross revenue for the year amounts to £8,481. 15s. 1d., and the gross expenditure to £5,049. 15s. 2d., the balance carried to the net revenue account being £3,431. 19s. 11d. The interest on loans amount to £1,781. 7s. 6d., and sinking fund instalment to £1,426. 5s. 1d., the net profit for the year being £224 7s. 4d. The balance brought forward from last year was £884. 12s. 6d., making a credit balance to be carried forward of £1,108. 19s. 10d. The amouns in the reserve fund on March 24 was £4,411. 18s. 5d The amount of energy generated has been 679,475 units, of which 576,853 units have been sold, being increases over the previous year of 89,842 units and 120,683 units respectively. The number of lights supplied on March 24 last, equivalent to 8 c.p., was 32,615, being an increase during the year of 4,144. The number of consumers added has been 75, and additional meters fixed 73 The number of consumers on March 24 was 396, and the total number of meters fixed 453. The maximum demand was on Oct. 20, 1899, the load at the station being indicated at 608 kw.; as compared with the previous year, 542 kw.; showing an increase of 66 kw. The greatest quantity supplied in 24 hours was on Dec. 23, 1899, being 3,883 units, against last year 3,198 units, an increase of 685 units. The supply mains have been extended a distance of 2,277 yards in the following streets: Henshaw-street, Barker-street, Wellington-street, Park-road, Brook-lane, Hardy-street, Waterloo-street, Gas-street, Greengate-street. The total length of mains laid on March 24 last was 14,768 yards. The prices charged for energy during the year have been as follows: without demand indicators—first 1,000 units or under per quarter, 4d. per unit; second 1,000, 3½d.; third 1,000, 3d.; fourth 1,000, 2½d.; fifth 1,000, 2d.; all in excess of 5,000 units, 2d. With demand indicators—all current consumed under two hours daily average maximum demand, per quarter, 4d. per unit; all current consumed in excess of two hours daily average maximum demand, per quarter, 2d. per unit; minimum charge for each meter fixed, 5s. per quarter. During the year contracts have been let for an additional engine and dynamo of 360 h.p. capacity, and for the extension of boiler-house, and four additional steam-boilers, etc. When these are completed the site of the present station will be fully utilised. The total horse-power in the station on March 24 was 1,800. Application was made to the Local Government Board for powers to borrow a further sum of £36,000 to carry out the extensions and additions to plant, and an enquiry was held on Jan. 9, 1900, but up to the present time their reply to the application has not been received. A plot of land at Greenhill, 17,360 square yards in extent, has been secured for the purpose of further extensions.

Number of public lamps		28
Total maximum supply demanded (kilowatts)		608

The reader may be reminded that a low-tension continuous-current system of supply is in vogue at Oldham, with a pressure at the consumers' lamps of 210 and 105 volts. Supply was started in March, 1894, the plant installed being of the non-condensing type. The loans sanctioned aggregate £52,000, of which sum £51,300 had been borrowed up to March, 1900, as against £49,600 to March, 1899. The analysis given below (supplied to us by the borough electrical engineer, Mr. S. Wilmott Newington) enables an interesting comparison to be made between the figures for the year ended March 25, 1900, and those for the previous financial year.

Analysis of Accounts for Year ended March 24, 1900

	1899-1900.	1898-1899.

TRURO ELECTRIC LIGHTING.

REPORT BY MR. F. H. HEADLEY.

The following is the text, condensed in parts, of a report now being considered by the Lighting Committee of the Truro City Council. Mr. F. H. Headley deals with both lighting and traction, and evidently has gone most carefully into the local conditions:

The area proposed to be lighted is that comprised within the municipal boundary of Truro. The boundary is extensive, the area within which contains a large mileage of roads, adjacent to which are very few houses, the lighting of which ceases at midnight, at an average cost of £1. 19s. per lamp per annum. I am of opinion that it will not pay you to lay cable and connections to light these, as the difference in the saving in the cost of lighting (if any) will not pay interest on the capital outlay. I therefore advise that the lighting be confined to what may be termed the habitable area, and only that portion of the area from which a private demand for lighting or power may be expected, and of such streets that form convenient connections for uniting the general network of distributing mains. From a cursory examination there would appear to be a large number, and, comparatively speaking, extensive areas of low ratable property, especially to the right and left of Kenwyn-street, Calenick-street, Charles-street, Fairmantle-street, Carclew-street, and others on the north side of the river, from which only in the ordinary way a very limited demand for private lighting may be expected, unless special inducements are offered to obtain such. For the size of the city there would appear to be an especially large amount of this class of property, and I consider for the success of any electrical undertaking the Corporation should undertake the free wiring of these houses, the payment for which shall be by prepayment meters; under these conditions I advise that the lighting of the habitable area be undertaken.

Public Lighting.—I understand that some lamps are left burning all night, others until midnight. I therefore advise that the streets be lighted by three classes of lamps—*i.e.*, (*a*) five-ampere enclosed arc lamp to burn until 11 o'clock, to have two brackets, one on either side of standard, for incandescent lighting to burn after that hour; (*b*) three 16-c.p. lamps in one lantern; (*c*) one 25-c.p. lamp in lantern. The three 16-c.p. lamps would, in the case of all-night burning, be so arranged that two can be turned off and one left burning. Under these conditions I estimate the lighting as follows: for convenience sake I propose to divide the city into two halves by the roads Richmond-hill, Frances-street, River-street, St. Nicholas-street, Boscawen-street, Princes-street, Quay-street, Boscawen Bridge, and Malpas-road, which should be lighted by means of 14 arc lamps, as per (*a*), as the bulk of the traffic would seem to concentrate in the above-named streets as far as Boscawen Bridge.

Then follows a schedule, which, while of interest locally, is hardly so valuable to our readers. Mr. Headley advises in the south of the city 15 groups of three 16-c.p. lamps and 55 25-c.p. lamps for street-lighting, while 2,520 8-c.p. lamps are expected to be required by private consumers. In the middle portion of the city the street-lighting would be done by 14 arc lamps, nine 25-c.p. incandescent, and one group of three 16-c.p. lamps. About 2,380 8-c.p. lamps are expected from private consumers. The northern division of the city would, it is assumed, take one arc lamp, 28 groups of three 16-c.p. lamps, and 50 25-c.p. lamps in its streets and 2,380 8-c.p. lamps for private supply.

The foregoing figures I believe to be practically the maximum, but it is not likely that the total of 8,000 8-c.p. lamps (or their equivalent) will be reached for some time. Still, I advise that the plant equal to this capacity be installed, as it is better to have too much than not enough, so as to obviate the error of not being able to supply your would-be customers (as was the state in Plymouth and elsewhere). Again, I advise that the streets as scheduled be lighted, believing that the fact of mains being in these streets often creates a demand which would never otherwise arise; in fact, it advertises the supply.

System of Distribution.—I advise that the system of distribution be by continuous current on the three-wire system at 460 volts across the outers, with 230 volts across the inners, at which pressure current would be supplied to consumers.

Maximum Load.—I estimate that, presuming with lamps installed both for public and private lighting as per the schedule herewith, the current required for 8,000 32-watt lamps burning would be equal to about 268 kw., but this is a condition that never occurs, as all lamps are never burning together at one period. I find the maximum load at Burton is in proportion to 1 to 1·5 lamps installed; at Bristol, 1 to 1·4; at Manchester, 1 to 1·6; at Altrincham, 1 to 3; and at Whitehaven, 1 to 1·3. Truro, however, will differ considerably to this. The high ratio of private houses to shops, and, again, the large number of ecclesiastical buildings and places of worship, will not produce so large a maximum load to the number of lamps installed. I consider that the ratio of 1 to 2 will meet your requirements. This, then, will give a maximum load of 147 kw.

Size and Site of Generating Plant.—I therefore advise that the generating plant be divided into two units of about 75 kw. each, with a third unit as a stand-by for breakdown, repairs, etc. The question of site is an important one, and should be as central as possible to the area of supply. I examined three sites, either of which might be made suitable—*i.e.*, Moresk Mills, by the river by new sewage works, and Lemon Quay. Moresk Mills offers a very advantageous site, especially as it has a small water power for about nine months in the year, and which I consider may be valued at worth about £75 per annum—that is, it will save coal to that extent. The buildings are, however, of little value for the class of machinery to be installed, except to make serviceable coal stores and workshops. There does, however, appear to be plenty of land suitable for the buildings, and the ground appears to be solid and firm for foundations. The site, too, is sufficiently far from habitation as not to be a nuisance to anyone. The site by the river by new sewage works is not so advantageous as the above, and is very de-central to the area of supply. I fear, too, it will be a costly matter to secure the foundations. On the other hand, if there is no purchase price to pay, the site can be made serviceable, but there will be a considerable increase in the price of mains on my estimate herewith. Lemon Quay offers by far the most central position, if the property can be obtained, but I fear the erection of a supply works here might be constituted a nuisance. Generally Moresk Mills offers the most serviceable site, but the question of expediency depends on the price of purchase, which has to be added to this estimate.

Capital Expenditure.—I advise that the generating plant consist of gas-engines working with Dowson or producer gas, and I estimate that the approximate cost of this will be:

Engines and dynamos	£4,000
Producer gas plant	1,000
Balancers	600
Accumulators, boosters, etc.	1,500
Switchboards, etc.	250
General equipment of engine-house	500
Mains, feeders, distributing boxes, and connections to houses	6,000
Meters and free wiring	1,500
New public lamps and alterations to others with connections	900
Buildings, etc.	1,250
Total capital expenditure	£17,500

Or equal to £81 per kilowatt.

Revenue.—I append a characteristic statement which shows at a glance the cost and profit, together with the price per unit sold, of various undertakings. I consider that the public lighting can be undertaken at 3d. per unit with the following results:

Candle-power of lamps.	Hours of burning per lamp.	Units consumed per lamp.	Cost of current per lamp.	No. of lamps.	No. of units.	Cost of current for lamps.
			£ s. d.			£ s. d.
500 c.p. arc lamp until 11 o'clock ...	1,233	616	7 14 0	15	9,315	116 8 9
Three 16-c.p. incandescent lamps until 12 o'clock	1,491	161	2 13 6	44	7,084	88 11 0
One 25-c.p. incandescent lamp	1,491	149	1 19 8	114	16,986	212 6 6
Extra for all night ..	1,375	137	1 14 3	50	6,850	85 12 6
Total cost of current per annum					40,235	502 18 9

In reality, however, the public lighting should only be charged the actual cost, which, by the appended table, ranges anything, from Manchester 1½d. per unit to a general average of 2½d. per unit. It is probable that the public lighting can be reduced. For the present, however, I estimate it at £502. 18s. 9d. Note 1.—This sum does not represent the total cost of public lighting, as there will still be about 50 to 60 gas lamps remaining in parts of the city where I have already described it will not pay to lay the mains. Note 2.—The method of switching on and off the public lamps may be done in several ways. In this case it is a somewhat costly matter to arrange the turning on from the station, as some lights are left burning all night. In some towns arrangements are made with the Watch Committee by which the police on their rounds switch on and off the light. I have therefore estimated for switching on and off the lights at about a dozen centres in the city, and which should be done by the undertaking in the cost of 3d. per unit. I estimate that with 8,000 8-c.p. lamps installed,

Digitized by Google

that the current consumed will be an average of 15 units per 8-c.p. lamp per annum, or equal to 120,000 units. The charge for current should be on a sliding scale—for instance, in those houses in which free wiring is undertaken, depreciation and interest on the capital expended must be added on the price to be charged per unit consumed. I consider that an average of 6d. per unit should be obtained, or equal to, say £3,000. There should also be a large demand for power, and this is a factor which should be thoroughly encouraged, as it provides a day load, and is therefore worked at, comparatively speaking, except for fuel, at little or no extra cost. It is difficult to place a figure for this, as the demand should be large, there being so many places where power is employed. I estimate, however, £200. Meter rents, sundries, etc., £150—a total revenue of £3,822. 18s. 9d.

Expenditure.—Coal, 400 tons of anthracite at 30s., £600; oil, waste, and stores, £50; wages, five men at 30s. per week, £390; repairs and maintenance, £200; public lamps, £100; rents, rates, and taxes, £100; management and office expenses, £500; interest, say 3 per cent. on £20,000, £600; redemption, 3 per cent. on £20,000, £600—a total expenditure of £3,140, leaving a balance of about £682 in profit. I might cite as proof that Tunbridge Wells, which has a plant about double the capacity, paid £900 towards the district rate, and carried forward a substantial balance. Of course, this result could not at first be expected, but represents the earning and paying capacity of the station.

Conclusions.—In conclusion, there would seem every reason and every prospect for an undertaking as described being a success. I scarcely need to detail the many advantages of municipalising the lighting undertakings. The fact that out of 155 provincial supply stations 95 belong to the governing authority, together with the chart which I append to this report, speaks for itself. Should you desire further information, I should be pleased to meet you to explain more fully verbally.

Electric Traction.

This question is a somewhat difficult one, and will require most careful consideration, more than it is possible to give at present in a report of this description. In the first instance, the traffic cannot be said to be heavy, but it can be said to be continuous.

Track.—In the second place, part of the track is exceedingly heavy, and, therefore, for the present purpose, I propose to treat it under two sections—*i.e.*, (1) Great Western Railway Station to Boscawen Quay; (2) from quay to Malpas. Practically speaking, from the quay to the junction of Richmond-hill with Frances-street there is a gradient or rise of about 1ft. in 300ft.; quay to Richmond-hill, 800 yards, 1 in 300 rise; Frances-street to George-street, 120 yards, 1 in 20 rise; Richmond-hill, 200 yards, 1 in 12·5 rise; Richmond-hill to Great Western Railway Station, 200 yards, 1 in 20 rise—total length, 1,320 yards. Taking a double-decked car with a seating capacity of 44 passengers, the total weight of which when full will be 11 tons, the car weighing eight tons when empty, the power required to drive such a car at eight miles an hour on level is 7·5 h.p.; at six miles an hour on level is 5·3 h.p.; on a gradient of 1 in 12, which is the steepest it has to negotiate, will be nearly at six miles an hour, 40 h.p. You will at once note that there is a vast difference of power required on the level and on the hill.

Size of Car.—I do not think it is possible or probable that a double-decked car will ever be filled, and I am inclined to advise single-decked cars of a capacity of 20 passengers each. These will weigh considerably lighter, and on the hill take much less power. I advise that in the event of traffic becoming too heavy for the cars in ordinary service, that more cars be run, believing that a continual or constant service of lighter cars would be more profitable than a less service of cars of larger capacity. I advise that there be three cars working on this section, each of which shall average six miles per hour, the three together giving a five-minute service.

System.—The system should be by means of the overhead wire and trolley system, the wire being supported on cast-iron columns, the same acting as the arc lamp standards. There should also be three turn-outs for crossing purposes.

Generating Plant.—It is scarcely practical to run the cars from the generating plant of the lighting system, as the switching on of the current, especially when manipulating Richmond-hill, would be too noticeable to the lighting. The same gas producer plant would, however, do, but it would be necessary to add another 75-kw. plant installed, together with a separate storage battery and booster. The plant should be so arranged that the stand-by set, or any set, can be used for either purpose, the same staff controlling all.

Capital Expenditure.—I estimate the capital expenditure—

Generating plant and accumulators	£3 500
Line equipment, mains, and feeders	6 500
Four cars, one as a stand-by	2,600
Total estimated expenditure	£12,600

Annual Expenditure.—I estimate the current consumption to be 2·2 units per round trip, or, say, a total of 97,032 units per annum—

Say at 2d. per unit, or at a cost of	£808	12	0
Five men at 30s. per week	390	0	0
Four boys at 7s. per week	72	16	0
Uniforms, etc.	30	0	0
Office expenses	75	0	0
Repairs, etc.	200	0	0
Three per cent. on £12 600, interest	378	0	0
Three per cent. on £12,600, redemption	378	0	0
Total expenses	£2,332	8	0

Revenue.—Presuming that the cars covered four round trips each per hour, I estimate the total mileage would be 67,176 car miles per annum, or equal to an expenditure of 8·55d. per car mile, and as each trip constitutes about 1·475 car miles, it practically means that if the fare is 1d., 13 people must be carried per round trip; anything above this number is profit. (The revenue at Dover is 10·92d. per car mile; South Staffordshire tramways, 13·95d. per car mile). You will notice that I have estimated the current at 2d. per unit; I do not think it is going to cost this to generate, as it constitutes mostly a day load, and the day staff can look after this. There is no doubt this will add some considerable profit to the lighting; but I have thought it safe to take this figure as a basis. You will see, on account of the heavy gradients, the working expenses are heavy. For instance, with a double-deck car the current consumption at Dover is only ·98 unit per car mile, but at Truro with a single-decked car it is 1·5 units per car mile.

Malpas.—I have not thought it worth while to go into the Malpas section; the character of the traffic seems to me to be so intermittent that I would prefer to discuss this section personally with you, as, indeed, I should be pleased to do with the whole matter generally. I trust this information will help you as a basis to formulate a scheme, for there is, undoubtedly, every element to ensure a successful undertaking.

Mr. Headley was also asked to report on the suitability of Carvedras Works as the central station, and he states:

The site is one of the best I have examined, being level, whilst it is sufficiently far from buildings as not to constitute a nuisance. The buildings, with very little alteration, could be made suitable for all purposes required. For the lighting scheme it is not quite so central as Moreak Mills; as a result an additional £1,200 may be required for extra feeders. For the traction scheme from Boscawen Bridge to station it is by far the best site, as it is so adjacent to that portion of the track which requires the heaviest amount of current, whilst there will be a considerable saving in the construction and feeders, equal at least to the extra expenditure on the lighting. If, however, the Malpas extension should be undertaken, the cost saved on the present traction scheme would be required for additional feeders. The water power at Carvedras is practically a negligible quantity, and is not worth consideration. In the event of coal being brought by rail the site is most convenient, as the coal could be tilted into bunkers.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Varna.—The Municipality invite tenders for the lighting of the town by electricity for 40 years by Oct. 15 (concession).

Warrington.—The Corporation invite tenders for the installation of mains and fittings at their station and depôt at Howley.

Beetle.—The Corporation invite tenders for a steam dynamo. Tenders by Oct. 13. Details in our advertisement columns.

Rochdale.—Tenders for the supply and fixing of a 1 ft at the infirmary, to be worked by electricity, will probably be advertised shortly.

Bermondsey.—The Vestry invite tenders for the erection of steam dynamos, etc. Tenders by Oct. 15. Details in our advertisement columns.

Swansea.—The Corporation invite tenders for the supply and erection of arc lamps, etc. Tenders by Oct. 10. Details in our advertisement columns.

Sunderland.—The Corporation invite tenders for 24 car bodies and electrical equipment. Tenders by Oct. 15. Details in our advertisement columns.

Maidstone.—The Corporation invite tenders for a surface condenser and feed pumps. Tenders by Oct. 16. Details in our advertisement columns.

Pozuelo (Province of Albacete, Spain).—The Municipality invite tenders for the lighting of the town by electricity for 40 years by Oct. 7 (concession).

Hackney.—The Electric Lighting Committee of the Vestry invite tenders for electricity supply mains. Tenders by Oct. 3. Details in our advertisement columns.

Birkenhead.—The Corporation invite tenders for the supply delivery, and laying of feeder mains, etc. Tenders by Oct. 2 Details in our advertisement columns.

Digitized by Google

Manchester.—The Tramways Committee invite tenders for the supply of cast-iron bases for tramway poles. Tenders by Oct. 1. Details in our advertisement columns.

Santiago.—Offers are invited for the laying down and working of a telephone system in Santiago de Compostela, in the province of Coruna, Spain. Tenders by Oct. 19.

Cortegana.—Offers are invited for the installation of electric lighting and the working of same for five years in this town, in the province of Huelva, Spain. Tenders by Oct. 19.

Azuaga.—Offers are requested by the Municipality of this town, in the province of Badajoz, Spain, for the installation and working of the electric light for 20 years. Tenders by Oct. 11.

Melton (Suffolk).—The Visiting Committee of the Suffolk County Lunatic Asylum invite tenders for wiring and fittings. Tenders by Oct. 5. Details in our advertisement columns.

Callosa de Ensarria.—Offers are requested by the Municipality of this town, in the province of Alicante, Spain, for the installation and working of the electric light for 15 years. Tenders by Oct. 12.

Fuenteovejuna.—Offers are requested by the Municipality of this town, in the province of Cordoba, Spain, for the installation and working of the electric light for 20 years. Tenders by Oct. 9.

Manchester.—The Directors of the Lancashire and Yorkshire Railway Company invite tenders for the supply of various stores. Tenders by 10 a.m. on Oct. 8. Particulars in our advertisement columns.

Ilford.—The Urban District Council invite tenders for meters (direct-current) and cut-outs. Specification may be obtained from Mr. J. W. Benton, clerk, Council Offices, Cranbrook-road, Ilford. Tenders by Oct. 8.

Whitehaven.—The Water and Lighting Committee of the Corporation invite tenders for the supply and erection of a switchboard at their electric lighting station. Tenders by Oct. 13. Details in our advertisement columns.

Aberdeen.—The Tramways Committee invite tenders for the manufacture and supply of 25 electrical tramcars, and equipments for six horse cars, about to be converted. Tenders by Oct. 17. Details in our advertisement columns.

Grimsby.—The Corporation invite tenders for the wiring of the free library for electric lighting. Specifications and forms of tender can be obtained from Mr. W. A. Vignoles, borough electrical engineer, Grimsby. Tenders by Oct. 6.

Middleton (Lancs.).—The Corporation invite tenders for buildings required for electricity station. Specifications, etc., may be obtained at the offices of Messrs. Lacey, Clirehugh, and Sillar, 78, King-street, Manchester. Tenders by Oct. 11.

Dublin.—The Corporation invite tenders for electric motors and pumps for Ringsend drainage works. Specifications may be obtained at the office of the consulting engineer, Mr. Chatterton, 6, The Sanctuary, Westminster. Tenders by Oct. 3.

Nottingham.—The City Council invite tenders for 1,500 tons of steel girder tramrails and 76 tons of fishplates. Specifications, etc., may be obtained from Mr. Arthur Brown, M.I.C.E., city engineer, Guildhall, Nottingham. Tenders by Oct. 8.

Bradford.—The Corporation invite tenders for the construction and delivery of an engine and dynamo, also switchboard apparatus, etc., for their destructor works, Southfield-lane, Bradford. Tenders by Oct. 9. Particulars in our advertisement columns.

Limerick.—The Town Council invite tenders for erection and completion of an electric generating station building at Frederick-street, Limerick. Drawings and specification may be seen at the office of Mr. J. J. Peacocke, B.E., city surveyor, Town Hall, Limerick. Tenders by Oct. 4.

Bray.—The Urban District Council invite tenders for supplies required at their electric light works for 12 months, including cables, carbons, house wires, switches, lampholders, incandescent lamps, etc. Particulars may be obtained from Mr. P. MacDonnell, clerk of the Council, Town Hall. Tenders by Oct. 4.

Glasgow.—The Corporation invite tenders for the supply of 1,000, 2,000, or 3,000 tons steel straight track rails; 100, 200, or 300 tons steel curved rails; 50, 100, or 150 tons steel fishplates. Specifications, etc., can be obtained from Mr. John Young, general manager, 88, Renfield street, Glasgow. Tenders by Oct. 23.

Eastbourne.—The Corporation invite tenders for the supply and erection of a water-tube boiler, with fittings, feed pump, etc., a 400-kw. steam alternator, with exciter (vertical enclosed high-speed engine), and main switchboard and connections. Tenders by Oct. 4. Particulars appear in our advertisement columns.

Sheffield.—The Corporation invite tenders for specification No. 3 (a) two two-phase steam alternators and exciters, 600 kw. each; (b) alteration of present single-phase plant to two-phase. Specifications can be obtained from Mr. S. E. Fedden, chief engineer and manager, Commercial-street, Sheffield. Tenders by Oct. 6.

Brighton.—The Council invite tenders for the supply and delivery of 2,000 tons of steel girder tramrails, 78 tons of steel fishplates, 90 tons of steel joists. Specifications and form of tender and all necessary information may be obtained on application at the office of Mr. Thos. B. Holliday, tramways engineer, Town Hall, Brighton. Tenders by Oct. 1.

Dublin.—The Electric Lighting Committee of the Corporation invite tenders for the supply and laying of electricity supply mains and accessories. Specifications and form of tender may be inspected at the office of the city engineer, Mr. Spencer Harty, M.I.C.E., City Hall, Dublin, and at the offices of Mr. R. Hammond, consulting engineer to the Corporation, 64, Victoria-street, S.W. Tenders by Oct. 4.

Medomsley (Durham).—The Parish Council invite tenders for the supply and erection of electric lamps, posts, cables, etc., necessary for the lighting of the road leading from Black Hall Mill to Medomsley Village, via Westwood Colliery. Particulars may be obtained from Mr. M. T. Milburn, Medomsley, R.S.O., clerk to the Council, and the ground may be viewed on making an appointment by letter.

Hackney.—The Electric Lighting Committee of the Vestry are prepared to arrange a sub-contract for the constructional ironwork required for the buildings of their combined electricity and refuse destructor works. Specifications, etc., may be seen at the office of Mr. Robert Hammond, M.I.C.E., 64, Victoria-street, Westminster, London, S.W., and may be obtained from the architects, Messrs. Gordon and Gunton, Finsbury House, Blomfield-street, E.C. Tenders by Oct. 3.

Brighton.—The Corporation invite tenders for the supply and delivery of 25 electric motorcars. The work is divided into three sections, and contractors may tender in respect of all or any one or more of such sections—viz.: (Section 1) 25 electric motorcar bodies; (2) 25 electric motor trucks; (3) 25 electric motor electrical equipments. The specification and form of tender and all necessary information may be obtained on application at the office of the tramways engineer, Mr. Thos. B. Holliday, Town Hall, Brighton. Tenders by Oct. 1.

India.—The Secretary of State for India in Council is prepared to receive tenders for the supply of a complete electrical installation for supplying power to a factory from a waterfall about three miles distant from factory. The generator will be required to develop about 500 kw., and the installation is to include complete plant of generators, line, transformers, cables, motors, etc. Conditions, etc., may be obtained from the Director, General Stores, India Office, Whitehall, S.W., and tenders are to be delivered at that office by 2 p.m. on Oct. 16.

Long Eaton.—The District Council invite tenders for the construction of a line of poles, also two wires (about 5·10 miles in length), with other accessories, for the purpose of establishing a telephonic and electro-mechanical transmitting and registering and recording apparatus between their waterworks pumping station at Stanton-by-Bridge, near Derby, and the service reservoir at Castle Donington, Leicestershire. Plan may be seen at the offices of the Council, Long Eaton, and specification, with form of tender, obtained on application to Mr. Frank Worrall, surveyor and waterworks manager, Council Offices, Long Eaton. Tenders by Oct. 1.

RESULTS OF TENDERS.

Witney.—The Hart Accumulator Company, Limited, have secured the contract for the supply of storage batteries required for the electric lighting.

Southampton.—The Guardians have accepted the tender of Lankester and Son for carrying out an electric light installation at the new workhouse infirmary at Shirley Warren, at £3,499. 10s.

Worksop.—The Urban District Council have accepted the tender of Mr. W. Hall, Potter-street, Worksop, in connection with the erection of electricity supply works in Canal-road, Worksop, at £3,950.

Greenock.—The Police Board have accepted the tender of the India Rubber, Gutta Percha, and Telegraph Works Company for Contract No. 6, and that of Messrs. Babcock and Wilcox for Contract No. 5, for the supply and erection of traction plant.

Shipley (Yorks.).—The Council have accepted the following tenders for steam exhaust pipes, storage battery, switchboard and connections, and cables: (Section A), J. Spencer, Limited, Globe Engineering Works, Wednesbury; (B), Eclipse Brass and Copper Company, Limited, Hull-road Works, York; (C), Mavor and Coulson, Limited, 47, King-street, Mile End, Glasgow; (D), Western Electric Company, North Woolwich, E.

BUSINESS NOTES.

TRACTION.

Sedgley.—On Monday a trial trip was made on the electric tramways at Sedgley which was considered to be satisfactory.

Falkirk.—Draft heads of agreement between the Council and Falkirk and District Tramways Company have been agreed to.

Gateshead.—The *Newcastle Daily Chronicle* comments favourably on the rapid progress which is being made in the laying of the tramways.

Nantwich.—The members of the Crewe Carters' Association have a strong objection to the proposed tramways on the ground of the narrowness of the streets.

Strike of Motormen.—We understand that the motormen and conductors in the employ of the Oldham, Ashton, and Hyde Electric Tramway Company came out on strike on Saturday night in consequence of the manager's discharging union employés and replacing them by non-unionists.

Glasgow.—The Corporation have agreed to take over the building contract at Pinkston power station and have appointed Mr. William Irving, works manager to Messrs. James Carmichael and Co., engineers and boilermakers, Dundee, to be mechanical engineer in charge of that station.

Digitized by Google

Preston.—Councillor Yates Foster (mayor) has been appointed chairman and Councillor Copland vice-chairman of the Tramways Committee. The town clerk is about to obtain from other towns information on the subject of tramways, so as to bring the return of information obtained in July, 1899, up to date.

Devonport.—We understand that the various road works necessitated by the tramways scheme, are making satisfactory progress. One or two sections are already well advanced, but it has been decided not to open the lines until the whole of them are completed. This it is expected will be about Christmas.

Bardsley.—At the Ashton County Police Court last week a carman was fined 5s. and costs for obstructing a tramcar belonging to the Oldham, Ashton, and Hyde, Electric Tramcar Company. Considering the trouble these people give as a rule the fine cannot be held to be deterring, especially as the advocate's fee was not allowed by the Court.

Accident.—For about two hours on Wednesday evening the electric train service between Moorgate-street and London Bridge Stations, *vid* the Bank, was suspended owing to an accident on the line. A train, the engine of which had broken down, was run into by a second train. The damage was evidently slight as no passengers complained of injuries, and soon after 8 p.m. traffic was re established.

Huddersfield.—The Town Council last week discussed the recommendation for the carrying out of new tramway works, relaying of old ones with electrical equipment, and the purchase of land, plant, and cars, involving an expenditure of £68,953 6s. 11d., already referred to by us. Finally it was agreed that application be made to the Board of Trade for powers to borrow £38,305 for tramway purposes, to be repaid in 30 years.

Chester.—The Chester tramways extension has been considered by the Local Government Act Sub-Committee of the Town Council, who have discussed the question of extensions generally, the desirability of taking powers for extensions in several directions, and carry out experimentally, in the first instance, the most important of them, and the question of double or single lines on various routes. The committee desired the surveyor and Mr. Thursfield to reconsider the subject, and authorised them to visit other towns.

Camberwell.—The London County Council have resolved, subject to the Vestries of Lambeth and Camberwell and the Lewisham District Board giving their consent to the proposed tramway and agreeing to contribute between them one-third of the net cost of the necessary street widening, to make application to Parliament in the session of 1901 for powers to widen certain thoroughfares with a view to the construction of a tramway. The estimated cost of acquiring the necessary property in the parish of Camberwell was £68,700, whilst the cost of the necessary paving works in Camberwell, excluding the cost of laying down and paving the tramway track, was estimated at £52,500. The Camberwell Vestry have decided to defer the consideration of a contribution to the cost of the new road to the Tower Bridge to the Borough Council.

Mersey Railway.—The first meeting of the Mersey Railway Company since the passing of the Bill enabling the company to be worked by electricity, extending the time for redeeming the redeemable first debenture stock, and constituting a joint committee with the Wirrall Railway, was held on Tuesday. Mr. James Falconer, who presided, said the effective working of the line by electricity would prove the practical salvation of the company. In reply to a question as to the cost of altering the system to electric traction, the Chairman said that for a joint scheme with the Wirral Railway Company they had provided in the scheme for borrowing powers of half a million. That was a rough estimate made by Messrs. Preece and Cardew. If the company did not come to terms with the Wirral Company, and had to raise the money on their own account, then he thought that the cost would be £300,000. This included provision for the rolling-stock—in fact, everything.

Folkestone.—The borough surveyor has been instructed to proceed with the preparation of the necessary plans for deposit in connection with the proposed application for powers to construct tramways in Folkestone. The report of Mr. J. E. Waller (of the firm of Messrs. Kincaid, Waller, and Manville) upon the proposal for the construction of tramways by the Corporation of Folkestone, together with the estimate of the cost thereof, was discussed at the last meeting of the Town Council. It was resolved that the routes of the proposed tramways be as follows: (No. 1) from the boundary of Cheriton to Radnor Park-road; (2) Radnor Park-road to Park-road; (3) Foord-road to Tontine-street; (4) Tontine-street and Harbour-street; (5) Black Bull-road, Canterbury-road, and Dover-road to Tontine street; (6) loop between Black Bull-road and Foord-road; (7) loop from the east to the west side of the Congregational Church in Tontine-street; (8) loop in Cheriton-road and Radnor Park-road; (9) Cheriton-road from Radnor Park-road to Guildhall-street; (10) Sandgate-road from the boundary of the urban district to Guildhall-street; (11) Rendezvous-street and Dover-road between Rendezvous-street and Tontine-street; (12) from the harbour along Marine-terrace, Marine-parade, and Lower Sandgate-road to Victoria Pier; (13) from the boundary of the urban district of Folkestone or Sandgate-road to the South-Eastern Railway Company's tramway in Sandgate. The recommendation of Mr. Waller to have a double line in Rendezvous-street has also been approved of, and the requisite steps will be taken for the promotion of a Bill in the next session to obtain powers for the Corporation to construct and work tramways as above indicated. The estimate is £95,000. It is calculated that the cars would run 360,000 miles per annum at a cost of 10d. per mile. The total cost of working expenses and repayment of capital would be £14,595. If the Corporation should purchase current of the existing company instead of erecting their own generating station, the capital cost would be reduced by £18,000.

LIGHTING AND GENERAL.

Buxton.—Application is to be made for £25,000 for electric lighting extensions.

Wisbech.—The Town Council have decided to apply for an electric lighting order.

Removal.—We notice that Messrs. B. Jackson and Co. are removing from 28, Fenchurch street to 38, Lime-street, E.C.

Globe Telegraph and Trust Co.—The directors announce a quarterly dividend of 1s. 9d. per share on the ordinary shares.

Walker.—The District Council have received £1,937 from the Electric Supply Company, this being the cost of the Council's opposition to the gas company.

Bishop's Stortford.—The North British Electricity Supply Company propose to apply for a provisional order authorising them to supply electrical energy in the district.

Carmarthen.—On Tuesday the Town Council appointed a committee to discuss the question of getting a preliminary report on the cost of an electric lighting scheme for the town.

Eastern Extension, Australasia, and China Telegraph Co.—The directors have declared an interim dividend for the quarter ended June 30 of 2s. 6d. per share, payable 15th prox.

Ormskirk.—The Guardians have appointed a sub committee to take into consideration the question of putting down an electric installation in the workhouse and offices for lighting purposes.

Walsall.—The Electric Lighting Committee's last report gives the total number of consumers supplied on Aug. 31 last at 167. The total units generated at the station during the month of August was 23,554

St. Olave's.—The Board of Works have given consent for the London Electric Supply Corporation, Limited, to lay distributing mains, etc., in Great Maze Pond, Tooley-street, Tower Bridge approach, and other thoroughfares.

Cannock.—The Urban District Council have decided to apply for a provisional order empowering them to provide electricity in the urban district. They will oppose the application of the North British Electricity Supply Company.

Poplar, E.—The electric light was turned on in the Poplar streets for the first time on Wednesday. The installation, when completed, will also take in the streets of Bow and Bromley, and has been laid down at a cost of £70,000.

Stock Exchange Settlement.—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to the Telegraph Manufacturing Company's further issue of 5,000 shares of £5 each, fully paid.

City of Buenos Ayres Tramways Co.—The directors have declared the following interim dividends for the half-year ended June 30: upon the old shares 4s. per share; 3s. 10d. per share upon the shares of the eighth issue; and 2s. 8d. per share upon those of the ninth issue; £10,000 is added to the reserve fund, and £2,057 carried forward.

British Power, Traction, and Lighting Co.—This Company has been registered with a capital of £52,000 in £1 shares, of which 50,000 are preference, the object being to adopt and carry into effect agreements made between the Engineer Cycle Works, G. J. Gibbs, and the Anglo-American Motorcar Manufacturing Company, and the Power Transmission and Traction Company, and others, to carry on the business of machinery manufacturers, electrical and general engineers, and builders of and dealers in all kinds of tramcars, etc.

Bristol.—The following report of the Electrical Committee will come before a special meeting of the Town Council to-day: "Your committee report that serious differences of opinion have arisen between the engineer and the architect with regard to the foundations for the proposed central electric lighting station at Avonbank. Your committee have given the matter their most careful consideration, but find that the points in dispute are of an important and complicated nature, and they therefore recommend that they be authorised to submit the matters in dispute to Sir Benjamin Baker, in order that he may advise which of the two schemes put forward should be adopted by the committee."

Appointments Vacant.—The Vestry of St. Mary, Islington, require the services of a mechanical draughtsman and an engine driver.—The Urban District Council of Barnes require an electrical engineer to act as clerk of works in connection with their electrical supply undertaking under the Council's consulting engineer, Mr. W. Fairley.—The Tramways Committee of the Manchester Corporation require the services of a thoroughly qualified person to act as lady superintendent of the ticket and cash counting department.—The Peterborough Corporation invite applications for the position of foreman jointer, at a salary of £1. 10s. per week. Full particulars of these vacancies appear in our advertisement columns.—An engineer is required by the Leicester Corporation at the new isolation hospital at Gilroes, Leicester, to take entire charge of the steam boilers, electric lighting plant, laundry machinery, heating apparatus, hot-water supply, sewage ejector, etc., for which he will be held responsible. A stoker will be provided. Wages, £2. 5s. a week. Applications must be endorsed "Engineer," and delivered at the office of Mr. James Bell, town clerk, Town Hall, Leicester, by 29th inst.

Digitized by Google

Wellington.—The Council intend to apply for a provisional order under the Electric Lighting Act for the present lighting area.

Harrow.—Notices have been published to the effect that the Urban District Council intend to transfer their electric lighting order to the Harrow Electric Light and Power Company, Limited, for a period expiring on Oct. 14, 1937.

Hanley.—Mr. H. P. Boulnois has held an enquiry into an application of the Corporation for sanction to borrow £9 500 for the provision of a refuse destructor near the Cauldon Canal at Sandyfield, and £4,000 for purposes of electric lighting.

Electro-Ceramic Syndicate.—This Company has been registered with a capital of £2,000 in £1 shares, the object being to acquire certain inventions relating to electro-ceramic photography, etc., from F. J. Shippey or Messrs. Shippey Bros., Limited.

Harrogate.—By invitation of the Mayor (Councillor Wilkinson), the members and officials of the Ripon Corporation, in view of the proposed introduction of electric lighting into Ripon, paid a visit to the Harrogate Corporation electricity works last week.

Paddington.—The Electric Lighting Committee, acting under instructions from the Vestry, have informed consumers of electrical energy that the consent of the consumer is necessary before any change can be made in the voltage under which current is supplied.

Southgate.—The Urban District Council have decided to apply for an electric lighting provisional order. A conference of the representatives of the Councils of Tottenham, Wood Green, and others combining in the electric lighting movement, was held on the 26 h inst.

Lymington.—The Council have approved of the manner in which the electric light company propose to carry out the work under their provisional order, and the contract with the company to light the town from Sept. 29 has been sealed. It is generally understood that the light will not be available until November.

Holyhead.—The Lighting Committee of the Urban District Council have been considering a scheme for lighting the town with electricity. It is contended that a great force of water is going to waste two miles away that could be utilised for this purpose. Mr. Thunderbolt has been requested to prepare a scheme for the town.

Clitheroe.—The National Telephone Company have declined to alter their rates for proposed telephonic communication, and the Corporation refuse to increase their offer. At the same time the Council have come to the conclusion that the town was not large enough to successfully maintain a local telephone exchange of their own.

Meyra Electric Co.—This Company has been registered with a capital of £10,000 in £1 shares, the object being to acquire a certain invention for improvements in galvanic batteries, with the trade mark "Meyra," and an invention or secret process for dry batteries, and to carry on the business of machine makers, electrical and general engineers, etc.

Northfleet.—On the agenda for the last meeting of the District Council was a motion to the effect that the necessary steps be taken for obtaining an electric lighting order for the district in the ensuing session of Parliament. It was not put to the vote, the mover withdrawing it so as to allow the clerk to ascertain the cost of an application for an order.

Accumulator Industries.—This Company has been registered with a capital of £10,000 in £1 shares the object being to adopt agreements (1) between H. Leitner, F. W. Manley (for the company), and B. Küttner, and (2) H. Leitner and F. W. Manley (for the company), to acquire certain benefits, rights, and inventions, and to carry on the business of electric accumulator, motor, controller, vehicle and dynamo makers, etc.

Post Office Telephones.—The application of the General Post Office to carry pipes through the galleries of the two subways running east and west between Farringdon-street, and situated on the north side of Holborn Viaduct, has been acceded to by the Court of Common Council, subject to the work being carried out to the satisfaction of the engineer, and to the payment of any reasonable fees to the city engineer for his services.

'English Illustrated Magazine."—Amongst the usual bright stories and sketches in the October number, we notice an article an article by Mr. Fred. A. Talbot, entitled "The Most Remarkable Railway in the World." It is an exhaustive description of the Wappee Valley Railway, well illustrated, with about 10 photographs and drawings, and giving the reader an excellent idea of one of the most daring as well as the most ugly mono-railroad constructions in existence.

Zschocke's Patent Water-Cooling Towers.—We understand that MM. Doherty and Donat, engineers and contractors, 40, South King-street, Manchester, are the sole licensees for Great Britain for these cooling towers for cooling the condensed water from steam-engines. We are informed that there are already over 600,000 i h.p. of Zschocke's patent cooling plants, including 35 electric light and power stations, in successful operation all over the world.

Craigo.—The electric light was switched on for the first time on Thursday last week at the local spinning mills. Messrs. J. D. Mackenzie and Co., Glasgow, were the contractors. The dynamo, of the multipolar type, is of American manufacture, having been made by the Bullock Electric Manufacturing Company, of Cincinnati, Ohio, and is capable of giving 130 amperes at 100 volts (when driven by belting from the main shaft) at a speed of 950 revolutions per minute.

Hackney.—At the Vestry meeting on Wednesday the Electric Lighting Committee reported on the applications received for the appointment of clerk of the works to supervise the erection of buildings for the electricity and refuse destructor works, and submitted the names of the three following candidates for the appointment of one of them by the Vestry—viz.: W. J. Davenport, 133, Rendlesham-road, Clapton; J. Saunders, Clifton Villas, Barclay-road, Walthamstow; P. Watkins, 1, Cleveland-villas, Ilford.

Nuneaton.—The Local Government Board have written, with reference to the Urban District Council's scheme for the extension and development of their electric undertaking, that the Board will raise no objection to the District Council proceeding with the erection of the chimney shaft, and ordering the machinery as proposed. When the Board have been furnished with a copy of the resolution of the District Council applying for sanction to borrow the further sum of £2,000, they will be prepared to sanction the total amount required.

Leicester.—The last report of the Gas and Electric Lighting Committee states that the accounts of the electric lighting undertaking have been submitted, and the result of the working of this department for the half-year ending June 30 last is a net profit, after paying interest on the capital of the undertaking, of £1,430. 8s. 5d. Out of this has been paid £1,068. 3s. 1d., the half-year's amount of sinking fund, leaving a balance of £362. 5s. 4d. The committee also report that good progress is being made with the extension of the electric lighting central station.

Barnsley.—The Park and Lighting Committee reported on Tuesday that they had given instructions to the electrical engineer to place standards for arc and incandescent electric light lamps—viz, one at the junction of the Sheffield and Doncaster roads, one at the junction of Cheapside and New-street, three on Mayday Green, one in Queen-street, one in Peel-square, three on Market-hill, one in Church street (at the top of Regent-street), two in Regent-street, one in Eldon-street (at the top of Kendray-street), and one in Kendray-street—and also to prepare specifications and tenders for an additional engine and dynamo for the electricity works. The committee will inspect the lamps and decide on alterations on Oct. 2.

London Gazette.—The first meeting in the estate of R. Foster, Bradley House, Nelson, Lancashire, and W. Baker, 27, Ormerod-road, Burnley, Lancashire (trading as R. Foster and Co. at Adlington-street, Burnley, also trading as the Nelson Electrical Engineering Company at Stobb-street, Nelson, Lancashire), will be held to-day at 12 30 p.m. at Exchange Hotel, Nicholas-street, Burnley, and the public examination at 11 a.m. at Court House, Burnley.—A meeting was held on the 25th inst. for the purpose of receiving the liquidator's final statement *re* the Electrical Pioneer Syndicate Limited.—Messrs. W. W. Feast, T. K. Freeman W. Langley-Smith, and W. Pering Paige have been appointed liquidators for the purpose of winding up the Croydon Tramways Company.

Catalogues.—We have received from Messrs. Mather and Platt, of Manchester, a revised list of their steel-clad motors and accessories. The list gives the weight, capacity, voltage, and price of the various types and sizes of motors manufactured by the firm. We have also received a copy of the illustrated pamphlet which they prepared for the purposes of the Paris Exhibition, in which is described some of their recent manufactures in electrical plant. This latter booklet is very well illustrated, the details in the machine shown being very clear. Messrs. Mather and Platt have, we notice, secured a gold medal at the Paris Exhibition for a combined engine and dynamo set.—We have also received from Messrs. Johnson and Phillips their new price list. They have, they state, owing to the slight fall in the market prices of raw materials, been enabled to give an additional 5 per cent. on the trade discount previously allowed off vulcanised rubber cables listed in their February, 1900, catalogue. Their additional cable factory for the manufacture of lead-covered and armoured cables for town lighting is now in working order, and they are at present executing a contract for the Manchester Corporation in it. The list is printed in black and red figures, and is very handy for reference.

Hampton.—Messrs. H. W. Handcock and A. H. Dykes, consulting engineers, of Westminster, and Mr. J. Kemp, surveyor to the District Council, have submitted a report on the proposed supply of electrical energy for lighting purposes in conjunction with a refuse destructor. There are at the present time 250 public gas lamps in the district, the cost, including repairs and cleaning, being £912. The lamp-posts belong to the Council, and it is proposed to adapt them by fitting them with 16 c.p. lamps with diffusing globes, which will give a far more effective illumination than the present 12-c.p. gas jets. The power taken by the 250 lamps when all alight would be 15·5 kw., or, allowing for loss in distribution, say 17 kw. Without considering the current which might be required for the lighting of the palace, the engineers estimate that within a very short time from the opening of the station there would be required for private lighting in Hampton Hill 600 16-c.p. or 1,200 8-c.p. lamps; Hampton, 600 16-c.p. or 1,200 8-c.p. lamps; Hampton Court, 300 16 c.p. or 600 8-c.p. lamps—making a total of 1,500 16 c.p. or 3,000 8 c.p. lamps. Of these 3,000 lamps, only about half would probably be alight at once, requiring (allowing for loss in distribution) an output of 50 kw. The maximum output of the station would therefore be: public lighting, 17 kw.; private, 50 kw.—total, 67. The most suitable position for the station would be, in our opinion, at the sewage works. Having in view the double purpose for which the destructor is required, first and foremost, the effective disposal of all refuse without nuisance from smell or dust; and, secondly, the production of steam. The adoption of the Meldrum type is recommended. The estimated total cost of the schemes, allowing for feeders sufficient for 10,000 lamps, as set forth is: electric

Digitized by Google

light station and mains, £15,450; and for refuse destructor, £3 425; while working expenses for electric light are estimated at £1,732 per annum, and for destructor at £398 per annum. As to revenue from electric lighting, the report says: "The number of units consumed per annum per lamp connected to mains varies in different districts, but from analogy with Kingston, where it is 26 units, and Ealing 23·2 units, and other neighbouring districts, we assume that each separate lamp in your district will take 22 units per annum. Taking the average price obtained as 6d. per unit, which is as cheap or cheaper than gas at the present moment, the annual revenue from the electric lighting department will be as follows: sale of electrical energy, £1,650; meter rents, £70; public lighting, £912—total, £2,632." Free wiring is advocated.

Brighton.—It appears that the Watch Committee have made a three years' arrangement with the Telephone Company in connection with the fire station telephones, notwithstanding the fact that it is expected to see municipal telephones well at work in Brighton within the next 12 months. A committee of the Guardians are considering a report as to the advisability of installing electric light at the workhouse, in which Mr. Christie, the resident electrical engineer of the Corporation, stated that he found, in the first place, it would cost the Corporation about £700 to extend the present main in Elm-grove to the workhouse, but by doing so 20 street lamps *en route* could be lighted electrically. Mr. Burden, the master, had informed him that there was approximately 1,000 gas-jets in use. Of these 400 were in use at once, and might be taken as the average maximum demand. The maximum demand, however, might be raised to 500 by using more light on special occasions. The hours of use of various lamps, he understood, might be taken as follows: 50, dusk to 8 p.m., equalled 730 hours per annum, or 36,500 lamp hours; 200, dusk to 11 p.m., equalled 1,820 hours per annum, or 364,000 lamp hours; 150, dusk to dawn, equalled 4,380 hours per annum, or 657 000 lamp hours, which altogether gave a total of 1,057,500 lamp hours. Assuming that all gas jets were replaced with lamps of an average of 8 c.p., each using 35 watts per hour, the annual consumption would be 37,012 units per annum. If the maximum demand did not exceed 400 lamps, or 14 units consumption per hour, then the cost worked out as follows: 5,110 units at 7d., £149; 31,902 units at 1d., £133—total £282, or an average cost of 1·8d. per unit. The capital cost of the whole installation, consisting of 1,000 lights wired, two 10-h.p. motors, and all accessories, might be taken at about £1,500.

Tewkesbury.—We are indebted to the *Tewkesbury Weekly Record* for the following description of Mr. W. Jackson's schemes, referred to by him at a recent meeting of the Town Council: "The system adopted should be the low-tension, the pressure on the lamps being from 220 to 440 volts, the generating plant to consist of two steam loco.-type boilers and two sets of combined engines and dynamos coupled direct and running at high speed and of the enclosed type. A battery of accumulators to be provided to take the light and night loads, and concentric armoured cables to be laid in the three principal streets, and also any cross streets between the same where current is demanded, the said generating plant to be capable of lighting 2 000 16-c.p. lamps, or 4,000 8-c.p. ditto. The street-lighting to be also on the incandescent principle, having one 25-c.p. lamp in each; the said street lamps to consist of a wood standard, on top of which will be fixed a wrought-iron bracket, with approved shape lantern with electric lamp inside, the whole well painted. This scheme is based on the understanding that the piece of ground at back of town hall be utilised for the building of the generating station, as by the same being so central considerable saving is effected in the initial outlay on plant and cables. There is also plenty of room for future extensions, or refuse destructor later on if required. The above site is undoubtedly the best, most central, and economical site for a generating station which could possibly be obtained. The working expenses would be reduced to a minimum by adopting such a scheme, as the generating station could be closed at 12 o'clock (or before) midnight, the demand afterwards being met by the battery. The charging of the battery would have to be done during the day, and the heavy load from sunset till 12 o'clock would be run direct from the engines with the battery as a regulator. For this plant, an electrician, fitter, stoker, and apprentice or lad would be sufficient for running satisfactorily. Installing work could also be undertaken from the same station by the Council, which is a very remunerative addition to the generating plant, needing a showroom, office, and stores, which we should be happy to superintend, paying the said Council a percentage on the turnover yearly. The price for current, we should say, should be 7d. per unit, equivalent to gas at 3s. 4d. per 1,000 cubic feet, and considering the latter to be well over 4s. per 1,000 cubic feet at present, we should say it would be very advantageous, profitable, and more economical to the Council and ratepayers to adopt an electric lighting scheme. We feel certain that in the course of two years after station has been opened, the price for current may be reduced to 6d. per unit (equivalent to gas at 3s. per 1,000ft.), and then will well repay the initial outlay on plant. An approximate estimate, to include the following: plain buildings, boilers and engines, pumps, etc., dynamos and switchboard, foundations, battery of accumulators, cables and laying, providing 100 lamp-posts and brackets, etc., would be £5,500-£6,000. The following is the estimate of returns: price for current 7d. per unit, one unit consumption of 18-c.p. lamps for one hour; calculating that the average consumer takes three units per day all the year round, and that 500 16 c.p. lamps are connected to main, £2. 9s. per day. So that it can be seen that if 1,000 8-c.p. lamps, or 500 16-c.p. lamps, can be connected to mains, that after interest, etc., depreciation, has been deducted, the scheme will very well pay."

Alloa.—The electric lighting of the burgh was discussed at considerable length at the last meeting of the Burgh Commissioners, and ultimately it was agreed that at the next meeting a small committee be appointed to determine the number of arc and incandescent lamps to be erected, the situation of these and the route of the feeders from the mains, and report accordingly to the engineers. Meantime Mr. Hogarth has been instructed to apply to the Secretary for Scotland to borrow £12,000 for the purposes of the scheme. This action was taken in consequence of a full report by Messrs. Buchan and Hogarth, electricians, Edinburgh, submitting a scheme of public and private lighting, prepared in view of the agreement entered into between the Commissioners and the British Electric Plant Company for the supply by that company of electricity in bulk. The current will be brought from the supply company's works by means of main feeder cables to the sub-station, which is proposed to be located at the burgh chambers, and from which sub-feeders will be led out to different points in the distributing mains. Current will be distributed upon the three-wire system, the declared pressure at the consumers' lamps being 220 volts. It is proposed that the principal streets should be illuminated by means of arc lamps, and about 32 lamps would be necessary for efficient lighting. Each arc lamp pillar would carry two incandescent electric lamps for use, say, after 11 p.m. Two hundred and sixty pounds might be saved by having only 24 arc lamps, with eight special incandescent gas lamps placed in positions where there is a considerable gap between the arc lamps. It has been arranged that the arcs should be run in circuits of eight each, and these could be switched on from the sub-station at the burgh chambers, thereby obviating the necessity of a man going round to each group of lamps. The solid system of cables is advocated. The capital outlay is estimated as follows: private lighting mains and sub-feeders, £2,594; public lighting mains, arc and incandescent lamp pillars, switches, etc., £1,300; roadwork—*i.e.*, excavation and making good of footways, etc.—£894; main feeders from company's works to Corporation sub-station, £2,700; sub-station switchboard and registering meters, main pilot wires, telephones, etc., £370; contingencies, £400; to which should be added: provision for consumers' services and meters, £600; engineering charges, and incidental expenses, £400, making a total of £9,258, and a loan of £10,000 is recommended. The engineers say, assuming that 5,000 lamps are connected, and that the supply company's estimates of maximum demand are realised, the annual cost would be as follows: private lighting maximum demand, say 70 kilowatts at £9, £630; street-lighting maximum demand, say 12 kilowatts at £9, £108; private lighting, say 70,000 units at 1½d., £417; street-lighting, say 31,200 units at 1½d., £195; arc lamp trimmer, £52; carbons, lamp renewals, etc., £20; office and sundry expenses, say £65; capital charges, 5¾ per cent. on, say, £9,000, £510—total, £2,005. They also append estimates showing how the revenue might work out, but consider that in Alloa the maximum demand method of charging would give eventually the best results. Revenue at 8d. and 2½d.: 24 street lamps at £20, £480; 105 kw. × 365 hours = 38,325 units at 8d., £1,277. 10*s.*; balance 70,000, less 38,325 = 31,675 units at 2½d., £330—total, £2 087. 10*s.* Revenue at fixed charge of 5½d.: 24 street lamps at £20, £480; 70,000 units at 5½d., £1,604—total, £2,080. Revenue at 7d. and 3d: 24 street lamps at £20, £480; 38,325 units at 7d., £1,118; 31,675 units at 3d., £396—total, £1,994. The charges for street-lighting are based on the assumption that each arc lamp burns until 11 p.m. all the year round, and the two incandescent lamps on each arc lamp pillar burn from 11 p.m. each night till sunrise all the year round. This would give respectively about 1,820 hours for the arc lamps and 2,500 hours for the incandescent lamps burning per annum. The actual cost of current for each combined arc and incandescent pillar would be about £13, and, adding a sum for carbons, lamp renewals, and proportion of trimmer's time, and also capital charges on outlay, this amount is brought up to about £19, which would be reduced to £18 if the 32 arc lamps scheme were adopted. The engineers also recommend that wherever consumers' mains are extended street-lighting should be adopted simultaneously, with incandescent electric lamps in the less important thoroughfares. The actual cost of current (exclusive of capital charges and lamp renewals) of a 16 c.p. street lamp burning till 11 or 12 p.m. each night, all the year round, would be less than 20*s.*, and burning all night, about 31*s.* per annum.

COMPANIES' MEETINGS AND REPORTS.

WILLANS AND ROBINSON.

Directors: Mark Robinson, Esq., M.I.C.E. (chairman); Sir Gilbert A. Clayton East, Bart. (deputy-chairman); Captain H. Riall Sankey, R.E. (retired), M.I.C.E; Lieut.-General Sir Richard H. Sankey, K.C.B., R.E.; Thomas O. Lazenby, Esq., J.P.

Thirteenth half-yearly report of the directors, to be submitted at the ordinary general meeting of the Company to be held at the Victoria Works, Rugby, on Oct. 3, 1900, at 2.45 p.m.:

After writing off as depreciation from plant, patents, etc., the sum of £5,630. 19*s.* 4d., and paying interest upon debenture stock, the balance to the credit of profit and loss account at the end of the half-year (including £5,212. 1*s.* 1d. brought forward) is £31,399. 8*s.* 11d. Out of this the directors propose that dividends be paid at the rate of 6 per cent. per annum upon the preference shares, and 10 per cent. per annum upon the ordinary shares, together amounting to £14,923. 17*s.* 10d. The

Digitized by Google

amount payable to the original directors, in accordance with the articles of association, being £4,218. 8s. 2d., the balance available is £12,257. 2s. 11d. From this the directors propose to carry £2,000 to the debenture redemption fund and £3,500 to the reserve fund, leaving £6,757. 2s. 11d. to be carried forward. The balance of the capital remaining to be issued under the authority of the extraordinary resolution passed on March 29, 1899—viz., 10,000 preference and 10,000 ordinary shares—was allotted to the shareholders in June last. The allotments were taken up as regards 8,788 preference and 9,425 ordinary shares, and the balance was so greatly over-applied for by the shareholders that it could only be allotted in about the proportion of one preference share for every 10 applied for, and of one ordinary share for every 50 applied for. The large engine, capable of working up to 3,000 i.h.p., exhibited by the Company at Paris, in conjunction with a dynamo by Messrs. Siemens Bros. and Co., Limited, has been awarded a grand prix, another similar award being made for the dynamo. The balance upon the share premiums account stood, at the commencement of the half-year, at £29,656 2s. Of this, in accordance with intentions expressed at previous meetings, £5,000 has been applied to a special writing down of the Company's property at Thames Ditton, and £20,000 has been transferred to the reserve fund. The balance, £4,656. 2s., has now been brought up again to £21,493. 2s. by payments under the first instalment of the premiums upon the last issue (1900). As one of the principal objects of both this and the preceding issues of capital was to enable the Company to make engines of large size, the directors are of opinion that the expenses incurred at the Paris Exhibition, which has served to introduce the Company's new work to the public, may fairly be defrayed out of the premiums account. Owing partly to difficulties in obtaining dynamos from the makers, and partly to other causes for which the Company is not responsible, an unusually large value of completed or nearly completed engines (all on order) remained in the accounts at the end of the half-year under the head of "unfinished work." Had it been possible to deliver and invoice these engines in the half-year, a larger amount of profit would have been brought into the accounts.

SEPTEMBER 17.

16500. **An improved high-voltage electric cut-out.** August Ecketein and Albert Julius David Krause, Peel Works, Adelphi, Salford, Manchester.

16501. **Improvements in arc lamp suspension apparatus, applicable also to other purposes.** August Ecketein and Arthur Ernest Angold, Peel Works, Adelphi, Salford, Manchester.

16507. **Improvements in or connected with the regulation and control of electric motors.** Wilfrid L. Spence and the British Electric Plant Company, Limited, 19, Waterloo-street, Glasgow.

16508. **An electric motor switch gear.** John Lenderyon and Edmund Francis Smart, 34, Clyffard-crescent, Newport, Mon.

16523. **An automatic safety clutch and ceiling rose for electric arc lamps.** Eric Philip Barfield, 8, Grosvenor-gardens, Muswell Hill, London.

16534. **Manufacture of porous metal plates for electric accumulators.** Frederic William Bühne, Birkbeck Bank chambers, Southampton-buildings, Chancery-lane, London.

16541. **Improvements in electric switching and metering apparatus.** James Grieve Lorrain, Norfolk House, Victoria-embankment, London. (Hector Alan Macdonald, France.)

16543. **Improvements in or relating to telephonic switch-boards and the like.** Koloman Nagy von Szopori, 322, High Holborn, London.

16545. **Improvements in arc lamps.** Charles Frederick Walter Dudding, 46, Lincoln's-inn-fields, London.

16567. **Improvements in or connected with therme-electric batteries or thermopiles.** Wilhelm Buchner, 47, Lincoln's-inn-fields, London.

SEPTEMBER 18.

16590. **Improved ear piece for telephone receivers.** Peter Maclellan and Thomas Rattray Small, 62, St. Vincent-street, Glasgow.

16644. **Improvements in electricity meters.** Sebastian Ziani de Ferranti, 18, Southampton buildings, Chancery-lane, London.

SEPTEMBER 19.

16667. **Improvements in and relating to the working of electric or other tramway or railway points.** William James Stewart, 96, Buchanan street, Glasgow.

16696. **Improved method of treating the animal or human body by electric forces.** Charles M. Johnson, Denmark House, Redhill, Surrey.

16697. **Improvements in systems of electrical distribution.** The British Thomson-Houston Company, Limited, 83, Cannon street, London. (Edwin W. Rice, jun., United States.) (Complete specification.)

16698. **Improvements in conduit ploughs for electric railways.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Joseph Hoffmann, United States.) (Complete specification.)

16699. **Improvements in lightning arresters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Louis Bell, United States.) (Complete specification.)

16700. **Improvements in systems of electrical distribution.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles P. Steinmetz, United States.) (Complete specification.)

16701. **Improvements in electrically-operated pumps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edward M. Hewlett, United States.) (Complete specification.)

16702. **Improvements in dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Edwin W. Rice, jun., United States.) (Complete specification.)

16703. **Improvements in controlling electric motors.** The British Thomson Houston Company, Limited, 83, Cannon-street, London. (Maxwell W. Day, United States.) (Complete specification.)

16704. **Improvements for adjusting brush holders for electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Henry G. Reist, United States.) (Complete specification.)

16705. **Improvements in systems of train control for electric railways.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Charles E. Barry, United States.) (Complete specification.)

16706. **Improvements in means for preventing hunting of dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Harold W. Buck, United States.) (Complete specification.)

16738. **An improved electric energy meter.** Felipe Saldanya, 4, South-street, Finsbury, London.

SEPTEMBER 20.

16777. **Improvements in or connected with electrically-ignited motorcars, cycles, or the like, applicable for other analogous purposes.** Joah Spencer Stafford, 8, Quality-court, Chancery-lane, London.

16798. **Improvements in underground conduits for electric conductors.** Josef Zappe, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16801. **Process and apparatus for the electrolytic decomposition of alkaline salt solutions.** Alberto Julio de Brito e Cunha, 4, South-street, Finsbury, London.

SEPTEMBER 21.

16808. **Improvements in and relating to the method of and apparatus for electrolytically depositing metal.** Reginald James Houghton and Walter Eskrigg Cook, 70, Market-street, Manchester.

Digitized by Google

16845. Improvements relating to electric igniters for explosion motors. Jean Marie Ricard and François Clement Gary, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SEPTEMBER 22.

16865. Improvements in and relating to devices for carrying electric cables, wires, and the like. Daniel Paul Regan, '96, Buchanan-street, Glasgow.

16881. Improvements in wireless telegraphy and telephony. Sidney George Brown, 9, Putney-hill, Putney, London.

16896. Electrical fittings for discharging cisterns. James R. Davidson and John Don, 53, King-street, Peterhead, N.B.

16898. Improvements in apparatus for electrically transmitting orders or signals, such apparatus being suitable for navigable vessels and other purposes where it is required to transmit a series of signals or orders. George Charles Shankster, 11, Church-street, Landport, Portsmouth.

16903. A new or improved device or apparatus for fixing electric lamps in the sockets of overhead electroliers, brackets, and the like, or for detaching them therefrom. William Veasey Biggs, 111, Hatton-garden, London.

16912. Improvements in or relating to covers or lids of telephone cases or the like. Horace Ashmore Jackson, 111, Hatton-garden, London.

16915. Improvements in the production of filaments for incandescent electric lamps. Fritz Dannert, 40, Chancery-lane, London. (Complete specification.)

16916. Improvement in or connected with electromagnets. Jasper Wetter, 37, Essex-street, Strand, London. (The Elektrizitäts-Aktiengesellschaft, vormals Schuckert und Co., Germany.) (Complete specification).

16930. Improvements in means and apparatus used for propelling boats by electricity. William Rowland Edwards, 65, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Oct. 13.

1899.

19810. Construction of wicks for oil lamps which are electrically lighted. Best.

20572. Air and water-tight telegraph transmitter keys for use in mines and other exposed places. Oppenheimer. (Actiengesellschaft Mix und Genest.)

22020. Telegraphy without the use of continuous wires. Thompson. (Braun.)

24297. Electric accumulators. Relin and Rosier.

1900.

6974. System or means for controlling or regulating electrical installations. Thompson. (Coerper.)

12321. Collector or commutator for electrical machines. Kaeferle.

12424. Manufacture of carbon for electrical and other purposes. Lake. (Burke, Kaufhold, and Russell.)

18810. Storage batteries. Rooper.

13972. Systems of electrical distribution. British Thomson-Houston Company, Limited. (Lunt.)

NOTES.

The Electro-Harmonic Society.—We have received the list of the committee and members of the Electro-Harmonic Society for the season 1900-1901. This is the fifteenth season of the society, and the monthly concerts will take place at the St. James's Hall Restaurant on Friday evenings, with the exception of that on Dec. 12, which is on a Wednesday. The concerts include four smoking concerts and two ladies' nights.

Santa Cruz Tramways.—We learn from a correspondent that in Santa Cruz, Teneriffe, an overhead trolley system of electric traction is being erected, and is shortly to be opened. The company which owns the line is a Belgian one, and it is stated that the King of the Belgians is a large shareholder in it. He has, we gather, visited the island recently in his yacht "Alberta," but whether to visit the tramway works or merely for pleasure we are unable to state.

Telephones in Hungary.—There is, we learn, about to be constructed at Budapest, at the expense of the Royal Treasury of Hungary, a central telephone station. This it is proposed to erect with a capacity of 10,000 subscribers at first, and capable of being extended to carry 20,000 subscribers. It is interesting to note that in the tenders which are now being invited for the work in this station all nationalities can tender, and we should think that some English manufacturers might well take advantage of the fact.

Electricity in Factories.—A new application of electricity as a motive power for workshop purposes is being planned at Sharpsburg, Philadelphia. The installation is being fitted in a tube mill, in which tubing from 9in. to 24in. is to be made. The rolls in the mill are to be equipped with independent electric motors driven by powerful dynamos, these being contained in a roomy power-house, which has already been erected. This mill, when finished, will form one of the largest tubemaking mills in America, and will be the only one at present existing which is run entirely by electricity.

Coast Lighting.—The new light which has recently been placed in the new lighthouse at Pendeen, on the north-west coast of Cornwall, was tried for the first time last week. The coast at this point has been the scene of numerous wrecks, and the light and the siren fog signal will be welcomed by navigators. The light gives four flashes in 15 seconds, and has an intensity of 57,000 c.p. Another new light was also inaugurated last Friday, this being in a bad portion of the Bristol Channel, and it forms part of a scheme for the better lighting of that portion of the coast. The light is similar to that in the Pendeen Lighthouse, and has the same intensity.

The Armour Technical College.—We have received a copy of the prospectus for the coming session of the Armour Institute of Technology, Chicago. The volume is similar to those issued by our own technical schools, and the subjects taken are practically the same. There are conducted in the college five courses of instruction—viz., mechanical engineering, electrical engineering, civil engineering, architecture, and the course in science. These include, broadly, the many technical and commercial subjects taken in our own institutions. The Armour Institute, of which an illustration is given, was founded in 1892 at Chicago by Mr. Philip D'Armour, of that city.

Electric Railways for Heavy Traffic. — The German Society of Mechanical Engineers is, we learn, offering a premium of £60 and a gold medal for the design of the best system of high-speed electric railways for heavy traffic. The conditions are for plans for a railway to connect two distant cities, upon which trains having a minimum seating capacity of 150 passengers may be operated at not less than 124 miles per hour. The contest closes Oct. 6 next, but we shall be surprised if any workable scheme will be sent in. Inventors who might possibly make a design which would work as required, would hardly be tempted to prepare plans for the sake of £60 and a medal.

A Hasty Spaniard. — That business gentlemen in England should, on using a telephone and finding they have been put on to the wrong number or switched off suddenly in the middle of a conversation, protest in a very vigorous fashion, is now a standard joke, but the anger exhibited does not usually go farther than words. The hasty temper of the Spanish race is proverbial, but one would not think that any man, however angry, would do deadly injury to the telephone instrument. This, however, is what occurred recently in Paris, when a Spaniard, who had been switched through by telephone from his hotel in Paris to a stranger instead of a friend, lost his temper and fired four shots into the instrument, entirely wrecking it. Naturally, he had to pay heavily for the repairs, and also to leave the hotel.

The London and Brussels Telephone. — The scheme which has several times been mooted for connecting Brussels and London by telephone seems at last to be on a fair way to becoming a fact. Thus it is stated that two proposals have been under consideration, one of which would involve the laying of a new cable across the North Sea. The other scheme proposes to use the Anglo-French line as far as the French coast, and from that point to use land lines to Brussels. This latter scheme seems to be the more practicable, and is said to be the one which will most likely be adopted. Either scheme would be costly, but the advantage to commercial men in both cities should quite justify the expense. The line is expected to be opened early next year, when the cost for a three-minute conversation is to be 2s. 6d., which would not be very dear, the present price for communication with Paris being 8s. for three minutes.

The Institution of Civil Engineers.—The council have, we learn, in addition to the medals and prizes given for communications discussed at the meetings of the institution in the past session, made the following awards in respect of other papers dealt with in 1899-1900: A George Stephenson medal and a Telford premium to Mr. L. F. Vernon Harcourt; Telford premiums to Mr. H. J. S. Heather, Mr. Walter Rosenhain, Mr. James Glover, Mr. A. B. Brady, Mr. R. C. Farrell, Mr. C. F. V. Jackson, and Mr. G. B. Walker. For students' papers, the James Forrest medal and a Miller prize have been awarded to Mr. C. B. Fox the James Prescott Joule medal and a Miller prize to Mr. J. W. Smith, and Miller prizes to Mr. B. Humphrey, Mr. H. E. O'Brien, Mr. H. E. Wimperis, and Mr. A. H. Morton. The council have nominated Mr. R. F. Whitehead to the Palmer scholarship at the University of Cambridge in succession to Mr. A. H. Kirby, who graduated last June.

Sweden.—What is probably the largest transmission plant in Sweden was recently inaugurated between Zoarnsweden and Domnarfoed. It has been put down for the Stora Kopparbergs Bergslag Company, and consists of four generators, each of 1,200 h.p., which transmit untransformed electrical energy at a pressure of 7,000 volts through 12 cables, partly to the Domnarfoed Ironworks, situated at a distance of 2¾ miles from the generating

Digitized by Google

station, and partly to paper works belonging to the same company. At both centres of consumption the high-pressure current is transformed down to 520 volts by means of nine transformers of 350 kw. capacity each. The transmission lines are run overhead, about 20½ tons of copper having been used for their construction. The generators are driven by water power, about 10,000 h.p. of the 18,000 h.p. at hand being available for electrical transmission, so that there remains still about 5,000 h.p. available for future extension.

Electric Canal Haulage.—An installation of electric traction has been made by the Société de Traction Electrique sur Voies Navigables along a distance of about 47 miles, from Béthune to L'Escaut. The boats to be drawn carry from 270 to 300 tons, and draw about 5ft. of water. The piece of canal fitted has six locks. The cost of steam traction or animal haulage is ·427d. per kilometric ton; for electrical haulage this is reduced to ·285d. The actual length of canal fitted for electricity is about 16 miles, and this is effected by two stations about 6¾ miles distant from each other and having installed a total power of 400 h.p. Continuous current at 500 volts is produced by eight generators. Overhead wires are hung on posts about 44 yards distant from each other at a height of 21½ft. above the towpath. The tractive apparatus consists of about 30 electrical haulers, each weighing two tons and mounted upon four wheels, of which only two are driven. The length of the haulers is about 14ft., the breadth being about 4½ft. The electric hauler can easily draw two 300-ton barges at a speed of nearly two miles per hour.

Loofah Storage Batteries.—We notice in the *Electrical World* that Mr. W. Bowker, sen., of Waltham, Mass., has taken out a patent for a method of cheapening and simplifying the production of secondary battery plates by utilising a natural vegetable fibrous network, such as loofah or luffa, as the binding medium for the lead oxide or active material, into which the active material or lead oxide is placed in the form of a paste. The network is thoroughly filled with this paste, after which the battery cell or plates are formed through a long and continuous charging of electricity, say, for 100 hours, more or less, or until the paste and network form a solid mass. After this the plates are in a condition to store electricity. The advantages claimed are as follows: The plates are light in weight and may be manufactured cheaply. The liquid acid can percolate through them quicker and more freely than in the ordinary way. It is found by actual test that the loofah resists the action of the acids used in secondary or storage batteries. The question of conductivity is conveniently ignored by the author when stating the advantages of his construction.

The Conductivity of Telegraph Cables.—There has been some question as to the reason why certain cables lose their conducting properties, and have, in some instances, to be replaced. Mr. Rheims has been endeavouring to find out the reason for this, and in consequence has submitted a paper on the subject to the Academie des Sciences. In this paper he states that when cables lose their electrical properties it is because they are always used for one kind of current only, either positive or negative. If used sometimes for positive and sometimes for negative, they will, he states, preserve their conductive qualities indefinitely. He illustrates this by an observation on an underground line between Paris and Dijon, the line having nine wires. Of these, wire No. 7 received alternately positive and negative currents. This line kept its conducting properties, while the eight other wires, which were used with Morse and Hughes instruments and only received positive currents, had all lost more or less of their conductivity. The remedy for this loss was stated to be obvious—namely, that all currents sent in one direction should be positive, those in the contrary direction being negative, thus destroying the action of the first current by that of the second.

A Heated Insulator.—Mr. A. Sinding Larsen, of Frederiksvaern, Norway, has protected a new form of high-voltage insulator designed with the object of getting over the condensation trouble. It is known that when very high voltages are used on overhead lines, it is not always possible to prevent a considerable amount of leakage which is due to the condensation of moisture on the surface of the porcelain or glass insulators. Mr. Larsen proposes to prevent this condensation by maintaining one portion of the insulator at a higher temperature than the air. This increase of temperature need be exceedingly small, and the author states that 1deg. C. is quite sufficient to prevent the moisture in the air condensing on one part of the insulator, as it will always choose the colder portion on which to be deposited. In order to obtain the heat at one portion of the insulator, a resistance coil is inserted into a cylindrical recess which is formed in the porcelain. This resistance wire can either be supplied with a current by means of an independent circuit, or when the main current passing along the high-voltage conductors is alternating, the heating current can be obtained by a small local circuit energised by induction. Of course, the energy required is quite small, so that it hardly enters into consideration when a large amount of power is being transmitted.

Proposed Pyrenees Railway.—Various schemes have been projected from time to time for bridging the Pyrenees by means of a railway, but hitherto without definite result, the consent of the authorities concerned not being forthcoming. However, we understand the well-known engineer, M. L. Rouvière, has taken up the attack. A scheme has been prepared by him which, it is understood, will probably find favour with the French Minister for Public Works. The route of the proposed railway is between Lerida on the Spanish side and the valley of Aran on the French side. Besides being the shortest, this route presents the least engineering difficulties. A tunnel 4,180 yards in length, with a station at either end, is included in the scheme. The necessary electrical energy for working the French section of the line could be obtained by utilising a series of waterfalls in the upper reaches of the Garonne, while the rapids of the Noguera-Ribagazzana would furnish the requisite power on the Spanish side. In order to improve the prospects of the undertaking, provision would be made for supplying the surplus energy from these sources to chemical or other works in the surroundings. It is reported that a German firm have declared themselves prepared to examine into the scheme, with a view to giving it effect should the necessary sanction be forthcoming.

Australian Tramways.—The use of electric tramways seems to be spreading to a very large extent in the various divisions of Australia. Thus, on July 11 the Electric Tramways Bill was read a second time in the South Australian Parliament. In this Bill it was proposed to altogether abolish the antiquated system of horse traction and substitute the modern system of electricity. The powers were asked by the Westinghouse and Callender Companies, who had obtained the right to purchase 60 out of the 70 miles of tramways in Adelaide and its suburbs. The cost of purchase is estimated at £400,000, and the expenditure to be incurred also £400,000. This latter, however, did not include the conversion of the whole of the lines. At Sydney also

Digitized by Google

the trams are being gradually converted from steam and horse traction to electricity, and a car-shed is being built which is to have a capacity for 120 electrical cars. Though not actually part of Australia, New Zealand is usually included in the Australasian Colonies, and it is interesting to note that in this large country also electricity is displacing other methods of traction for tramways. The Harbour Board engineer of Wellington has, we learn, been sent to America to decide as to the best system of electrical traction to be adopted on the Wellington tramways. The Auckland electrical tramways scheme is also shortly to be put in hand, and a very extensive system is contemplated.

The London United Tramways.—The conversion of the extensive system of tramlines owned by the London United Tramway Company to electric traction is practically completed, and the generating works are also in such a state that the tramways could be run almost immediately. The whole matter, however, is hung up because the report of the commission appointed by the Board of Trade to consider the protective clauses which should be enjoined on the company for the benefit of the Kew Royal Observatory has not yet issued its report. This committee was appointed in November last, and carried out, we believe, some very extensive experiments in the early part of the year. The composition of the committee, to which we referred at the time, was all that could be desired, in that it comprised the extremists of either side, ranging from Prof. Ayrton, who was inclined to accept nothing but an insulated return, to Mr. Parshall, who believes in insulating the Royal observatories by transporting them to uninhabited regions. We regret, therefore, that this collection of gentlemen, who have the matter at their fingers' ends, have not been able to come to a prompt decision as to the case before them. In the meanwhile the tramway company has not cared to suspend work altogether, and has equipped the overhead line on the single trolley wire system, while the rails have been bonded for an earth return. We trust that when the tardy decision of the committee is at length given, no extensive alterations will be required in the work already done.

The War Fund.—The gas and electric lighting department of Leicester have, during the past 11 months, endeavoured to prove their loyalty to their country. In the first instance, many of the employés in this department were called out as reservists, and again, some of the electric lighting department joined the service contingent of the Electrical Engineers Volunteers which is now with Colonel Crompton in the Transvaal. They have also shown their patriotism in another way, and since December last the employés have contributed amounts according to their station, and in the 42 weeks up to Sept. 21 last the large sum of £322. 4s. 6d. has been raised in the department for the "Soldiers' Fund." The object of the fund was to help support the wives and children of the local men who were called to the front, and £205 was, for this purpose, contributed to the Leicestershire Army Reservists' Fund. The sum of 15 guineas has, however, been expended in other things—viz., the Leicester Regiment "Shirt' Fund, the Ambulance Equipment Fund, and the Yeomanry Hospital Fund. The war being now practically at an end, the committee have now decided to close the fund, leaving £101. 9s. 6d., which is to be voted on the conclusion of peace or the return of the troops. The engineer, Mr. Alfred Colson, who is also president of the fund, in the financial statement which we have before us expresses his personal gratification at the large sum raised, and thanks the men who contributed to the realisation of this good result.

A New Automatic Cut-Out.—An article contributed by Mr. Hermann Müller to the *Elektrotechnische Zeitschrift* calls attention to the fact that in the ordinary type of maximum current cut-out, the hand lever is so interconnected with the circuit-making spring that the closing of the hand lever simultaneously effects the closing of the main circuit, the latter remaining closed so long as the lever handle is held in the closed position by electromagnetic influence or otherwise. But this feature might be attended with undesirable consequences should the excess current, which in the first place caused the automatic opening of the circuit, be still extant at the moment of switching in. In order to remedy this defect, resort is had in practice to the provision of a supplementary hand switch, which must always be closed after the automatic cut-out has been readjusted. The arrangement, however, entails increased vigilance on the part of the attendant. The article in question then goes on to describe a form of automatic cut-out recently introduced by Messrs. Schuckert and Co, of Nürnberg, whereby the above-mentioned defect is remedied in a seemingly simple manner. In this cut-out, between the lever handle and the movable parts of the switch which close the circuit, is placed a spring detent, which is released automatically by the influence of the line current so soon as the current flowing through the switch reaches the prescribed maximum. Thereby the circuit-closing portions of the switch are also released, and assume the "off" position either in virtue of their own gravity or with the aid of a spring. The article describes the construction of the switch in detail, the text being supplemented by several diagrams and photographic reproductions. It will be remembered that Mr. L. Andrews, of Hastings, has designed a non-return and maximum cut-out which has the same properties.

Telephones in the Philippines.—There is, we notice, in the *Western Electrician* an interesting account from its special correspondent in the Philippines of the difficulties met with in building telephone lines in the Philippine Islands. There is, we learn, a telephone service in Manila, but this was erected by the Spaniards, and is so inefficient that it merely serves to show the necessity for a better service. The system has, however, improved considerably since the American occupation, and some benefit is now to be derived from the line. The reason given for the bad state of the Manila telephone service is that the Spaniards have used such frail poles, and have generally secured the wires in a very insecure fashion. The American system is, however, about to be adopted in consequence of the great demand, and a good up-to-date service is to be installed. In the southern islands the state of things is much worse, the inhabitants never having seen telephones, except perhaps such ones as have been fitted by the American Army Signal Corps. In many places the natives are afraid of the lines, and are, in consequence, not very likely to damage them. Anything loose is, however, a special mark for the Filipino, and while in one instance the poles and wires were left alone, everything loose, such as a box of insulators, nails, screws, coils of wire, etc., was taken. The poles and fittings once in position are usually safe from the average native, the danger of destruction being from the insurgent Filipinos. The penalty the native has to expect for tampering with the wires is to be shot on sight by the line guards, and this prevents much damage. Occasional shocks, also, from the wires tend to make the natives fear the lines, and the insurgents also has this fear to some extent. This was shown by the fact that, when wishing to destroy some line, they chopped down the posts for about half a mile, but did not dare to touch the wire, which still worked without interruption.

Becquerel Rays.—The subject of Becquerel rays has been much discussed recently, and Mr. Oscar M. Stewart has thought fit to bring up to date, in the *Physical Review*, a *résumé* of the matter given in that journal some two years ago. In the present *résumé* he speaks of the substances, in addition to uranium, which have been found to emit these radiations. He goes on to deal with the fluorescence and phosphorescence of these rays, their relation to the conductivity of gases, the absorption of the rays, their chemical effects, their secondary or induced activity, the thorium radiations, and the magnetic and electrostatic effects of the rays. The *résumé* is too long to describe with more detail, but the theories given concerning the origin of the Becquerel radiation are of great interest. Thus the author states that many theories have been suggested concerning them. Madame Curie first suggested that the energy may be due to a very penetrating radiation hitherto unknown, which could excite fluorescence in some substances. Sir William Crookes suggested to the British Association in 1898 that in some way the energy might be obtained from the rapidly-moving air particles. Messrs. Elster and Geitel took a salt of uranium into a deep mine, where it was protected by 2,785ft. of earth from external radiations, and the salt was still active. When kept in a high vacuum the radiations were still emitted, the energy thus not being due to a mechanical or chemical action of the air. The impact of X-rays or cathode rays was also found to produce no change in the radiation. Messrs. Elster and Geitel suggested that the energy may come from an unstable molecule gradually passing over into a stable state, this idea being also supported by Behrendsen. Until the discovery of the magnetic deflection of Becquerel rays, it was thought that they were X-rays of feeble intensity. As the rays belonging to the deflectable group carry negative charges, they probably consist of small particles of matter, as matter and electrical charges are, as far as is known, inseparable. According to the theory used to explain the Zeeman effect, each molecule has revolving round it at a high speed one or more small satellites negatively charged. Measurements based on this theory have shown that the ratio of charge to the mass of a satellite is of the same order of magnitude as that obtained for the cathode ray particle or for the deflectable Becquerel rays. In the molecular groupings of the radio-active elements they may, the author thinks, be conditions of instability such that some of these satellites could be lost from their molecules, and moving off at high speed become the deflectable Becquerel rays. The theory that Becquerel rays consist of extremely short ultra-violet rays is now almost abandoned, and it is believed that they, like the cathode rays, are negatively-charged particles of matter moving at extremely high velocity. Prof. J. J. Thomson has shown that the ratio of charge to mass for the negatively-charged particles in gases at low pressures is a constant, and if this is true, it is the velocity which varies. The difference in penetration is then explained by a greater velocity for the Becquerel ray particle—the greater the velocity the higher being the value in the cathode rays.

The Production of High Temperatures.—The paper read by Mr. E. D. Lange before the Paris meeting of the Iron and Steel Institute is of great interest to all engineers, although its particular applications deal with metallurgical operations. The author does not refer in this instance to the electrical furnace as a means for producing extremely high temperatures, but to the system invented by Dr. Hans Goldschmidt. This system, which is being experimented with largely at Essen, is not altogether new, and is based upon the heat of combination given off when aluminium is ignited in contact with certain metallic oxides. The author in his paper refers to the work which had been done previously on the same lines, particularly mentioning the work of Mr. R. A. Hadfield, who in 1895 succeeded in producing extremely pure iron by reducing ferrous oxide with aluminium. Dr. Goldschmidt's experiments were made with the object of discovering a mode of controlling the violent reaction obtained by the heating of aluminium in contact with metallic oxides, and these brought to light the important fact that it was not necessary to heat the whole mass up to the requisite temperature for ignition, but that it sufficed to start ignition at any one time. When combustion once started the reaction proceeded steadily with more or less speed throughout the whole mass, thus generating within itself the whole of the heat required. In the case of the refractory oxides, it would have been a difficult matter to apply the requisite heat for ignition at any point had not Dr. Goldschmidt made the still more important discovery that, although certain oxides combined with aluminium at so low a temperature that they could be ignited with an ordinary match, yet they nevertheless, in their combustion, developed so much heat that if a small quantity of these oxides was placed upon a mixture of refractory oxide and aluminium and ignited, a reaction was started in the same, which, thus originated, then proceeded automatically as before. The heat developed by the combustion of a mixture of alumina and iron is sufficient to start the reaction between the aluminium and iron oxide mixture, and as this proceeds, more and more of the same is added until within a minute or two there is a crucible containing reduced iron covered by a thick coating of alumina slag. On pouring off the slag, the temperature of the underlying liquid iron can be tried by pouring it on to a mild-steel plate or along the side of a mild-steel bar, when the hot iron cuts its way through with ease. Pyrometer experiments have established the temperature reached in the operation at between 2,900deg. C. and 3,000deg. C., that is to say, 1,000deg. C. more than that reached during the hottest period of the Bessemer blow. In the case of the reduction of chrome from its oxide by this method, the temperature of 3,000deg. C. is certainly reached—a temperature hitherto obtainable by the electric arc alone. In the paper a system of welding together iron bars or rails was also described, in which the heat for the weld was obtained from the combustion of aluminium and iron oxide. It is estimated by Dr. Goldschmidt that it is commercially economical to connect in this way the rails of a tramway system, and he maintains that the cost of upkeep will be considerably less with joints made in this way. It would, of course, considerably increase the conductivity at the joints, and perhaps do away with the bonding which is now absolutely necessary.

Accumulator Traction.—In a contribution to the *Centralblatt für Accumulatoren und Elementenkunde*, Mr. Johannes Zacharias takes exception to certain statements which have appeared in the daily Press with regard to the abandonment of accumulator cars on the Berlin tramways. He admits the high initial outlay and subsequent cost of working entailed by accumulator traction, and, further, that the system requires greater skill and technical knowledge on the part of the staff than the former service of horse cars, while the considerable dead weight represented by the accumulators is also undisputed. But these, he points out, are facts, which it requires no experiments to prove. The cost of a battery, its weight, etc., were fully known long before the introduction of the mixed system of working in Berlin. It was known exactly how heavy the battery would be, how often it would have to be recharged, and also that the battery would be capable of

Digitized by Google

accomplishing from 25,000 to 27,000 car miles before it became necessary to renew the bulk of the positive plates, while the negative plates might have to be renewed earlier. The difficulties presented to the efficient working of the system in winter are next dealt with, the inevitable loss of energy through the slipping of the driving wheels on ice-covered rails, and the increased consumption of energy entailed by more frequent stoppages, tending to untimely exhaustion of the battery, being pointed out. The latter faults, however, would not be serious in effect were it not for an apparent defect in the calculations for the overhead trolley system with which the accumulator cars work in conjunction, whereby in the event of a number of trolley cars coming to a standstill within a short distance of each other and then starting up together, there is so considerable a drop in the line voltage as to render liable a discharge from the accumulators into the line, whereby the battery is discharged instead of being charged. It is stated that drops of as much as 100 volts in the line pressure have been frequently observed, so that it was naturally impossible when these drops occurred to charge the accumulators during the journey of the car, and as no serviceable instruments have been provided whereby the current and voltage might be observed, the conductor consequently has not known whether the battery was being charged or discharged, and it has happened that a battery instead of receiving a charge has discharged itself, acting meanwhile in the capacity of a buffer battery. Considerable variations in the line voltage have occurred, especially over the suburban stretches of the trolley-equipped track, and at outlying depôts, so that even after the return of the cars in the night it has been impossible to charge the accumulators. These facts do not prove the uselessness of accumulators for traction purposes, but rather the difficulties attending the correct initial calculation and apportionment of such an extensive system of conductors and feeders. The defects of the system have been lessened by adding new feeders at suitable points, but not entirely removed. In the author's opinion, a complete remedy will not be effected until buffer batteries have been provided at the extremities of the system, especially as considerable excess voltage has also been observed, varying up to 600 volts from the normal line pressure of 500 volts. As a practical proof of the adaptability of accumulators for traction work, even over extensive systems of lines, the author instances the Hanover tramways, in which case, however, the problem has been tackled in quite another manner. Not only has Hanover adopted the accumulator system of traction with intelligence and care, but has also proceeded so far as to establish an accumulator factory of its own, where it manufactures its own plates. Mr. Zacharias's exposition of his case certainly tends to show that accumulator traction in conjunction with the overhead trolley system of working has not been accorded a fair trial in Berlin, and that the failure of the accumulator service of cars may have been due rather to temporary defects in the allied system than to inherent faults of its own. However, it is impossible to come to a definite conclusion in the absence of all the facts.

Electric Light Provisional Orders.—The report of the Board of Trade respecting the applications made to them for the past year has just been published. The report is dated June 22, and only contains information up till then. In it particulars are given as to how the Board of Trade has treated the various applications, and this will be found in full elsewhere in this issue. It must be remembered, however, that after the Board of Trade has given its decision in any particular case that decision has to be confirmed by Parliament. As an example of this, we may quote the Marylebone order, which was recommended by the Board of Trade to be granted to the company known as the Marylebone Electric Supply Company, Limited. This order was not confirmed by Parliament. Interest centres round the reasons given in the report for the granting or refusal of certain provisional orders. It will be noted that where the local authority applies for an order, the Board of Trade has in every case granted the necessary powers to enable them to supply electric lighting. When, however, the application is made by a company, the result is by no means certain. Thus, amongst the applications made last year by companies, no less than nine provisional orders have either been refused altogether or have had their area of supply considerably restricted because the company has not been able to obtain the consent of the local authority interested, or to prove to the Board of Trade that there are reasons why this consent should be dispensed with. We are pleased to note, however, that in four of the cases this consent of the local authority was done without. Amongst these four was the Marylebone order, which was not confirmed by Parliament. Still, by its decision in this case and the other three instances, the Board of Trade clearly shows that it will not allow a local authority to obstruct the introduction of electric lighting into their district unless there is a reasonable ground for the obstruction. The most reasonable ground in these cases is the fact that the local authority themselves will undertake the work, and that they propose to obtain a provisional order. This was so in the case of Hebburn, which objected to be supplied by the County of Durham Electric Power Distribution Company. In one other case, where both a company and a local authority applied at the same time, the local authority naturally obtained the desired powers. Another reason for refusing the order was that given in the case of Southwold, where the order was not granted on the ground that the promoters failed to prove that they were financially capable of carrying out the work. This is a very reasonable ground for refusal, as the Board of Trade rightly condemns all trafficking in electric lighting orders. In one case the order failed because the promoters did not prove their compliance with the Electric Lighting Acts and also the rules of the Board of Trade. The Board of Trade also refused to grant an order to cover areas which were not contiguous. Thus in one case, where a company applied for the burghs of Bridge of Allan and Dunblane, because the consent of the local authority over an intermediate piece of land could not be obtained, the order was granted only for Dunblane burgh. The same thing occurred in one other order. This seems to us to be somewhat unreasonable, as of late there has frequently been permission given to owners of provisional orders to erect their works outside their area, and to lead their mains from the stations through a district which is not served. If this is so, we fail to see why absolute continuity in areas should be a *sine quâ non* in provisional orders if the two districts which are to be served are not widely separated, and are suitable for a joint supply. The session's work results in 59 orders having been issued to local authorities and 39 orders to companies, out of a total number of 108 applications, 10 being refused. These figures show that there is good prospect for electrical manufacturers obtaining contracts for electric lighting plant in the near future. Amongst the other interesting items in the report is a tabular list of all the orders which have ever been granted, with notes as to whether they have been revoked or repealed. We gather from these lists that two Irish orders—the Kilkenny and Waterford—were revoked in August last, because the Corporations of those towns had not proceeded to carry out the same.

THE ELECTRIC LIGHTING OF THE CITY OF GLASGOW.

St. Andrew's Cross Station.

In addition to the Port Dundas station already described, the electrical necessities of Glasgow are met by the Waterloo-street station and by the Kelvinside station; the latter was acquired by the municipality from the Kelvinside Electricity Supply Company about a year ago. All these stations are situated on the north side of the River Clyde, and until recently no attempt was made to provide a supply of electricity on the south side, which contains, in addition to a fairly large business area, several important residential districts. To serve these, the St. Andrew's Cross station was planned, and although officially opened on the same day as the Port Dundas station, it is as yet in an unfinished state. At the time of our visit some machinery had been installed, and the officials hoped to be able to supply current in about six weeks.

The buildings, an elevation of which we give in Fig. 14, are of terra-cotta brick, and, unlike the Port Dundas station, have all been erected at once to save any delay when extensions are decided upon. As the buildings stand, accommodation is provided for some 15,000 h.p. It is interesting to note in this connection that 1 h.p. is got for every 3·4 square feet occupied by the engine and boiler house, while at Port Dundas station, which has a capacity of more than double that of the station now under consideration, a horse-power is obtained for every 2·85 square feet of ground covered by engine and boiler houses, showing the economy of large stations where ground is costly. In some provincial towns we have observed that the space occupied by small works gives about 1 h.p. for every five to seven square feet of engine and boiler space.

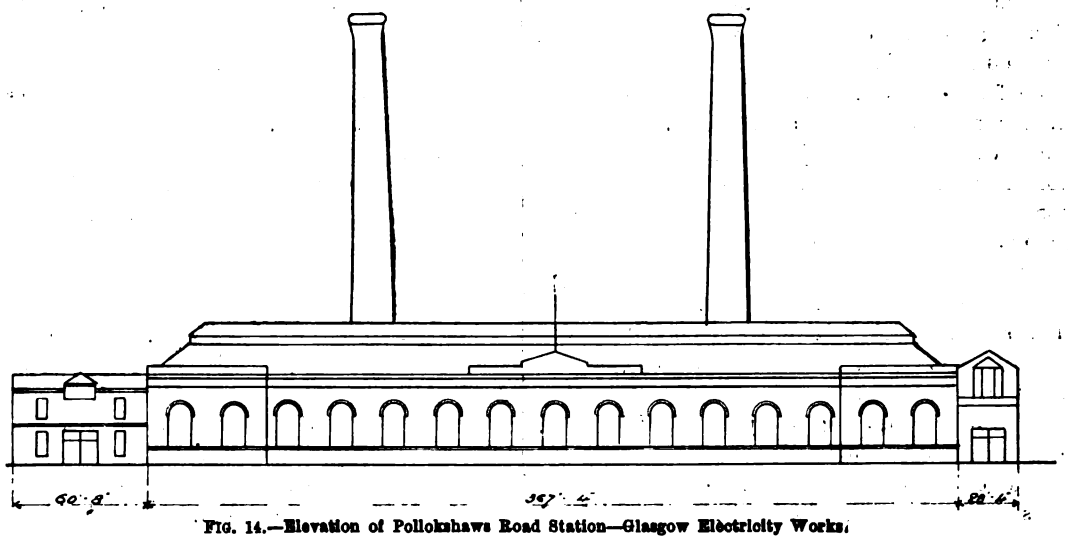

FIG. 14.—Elevation of Pollokshaws Road Station—Glasgow Electricity Works.

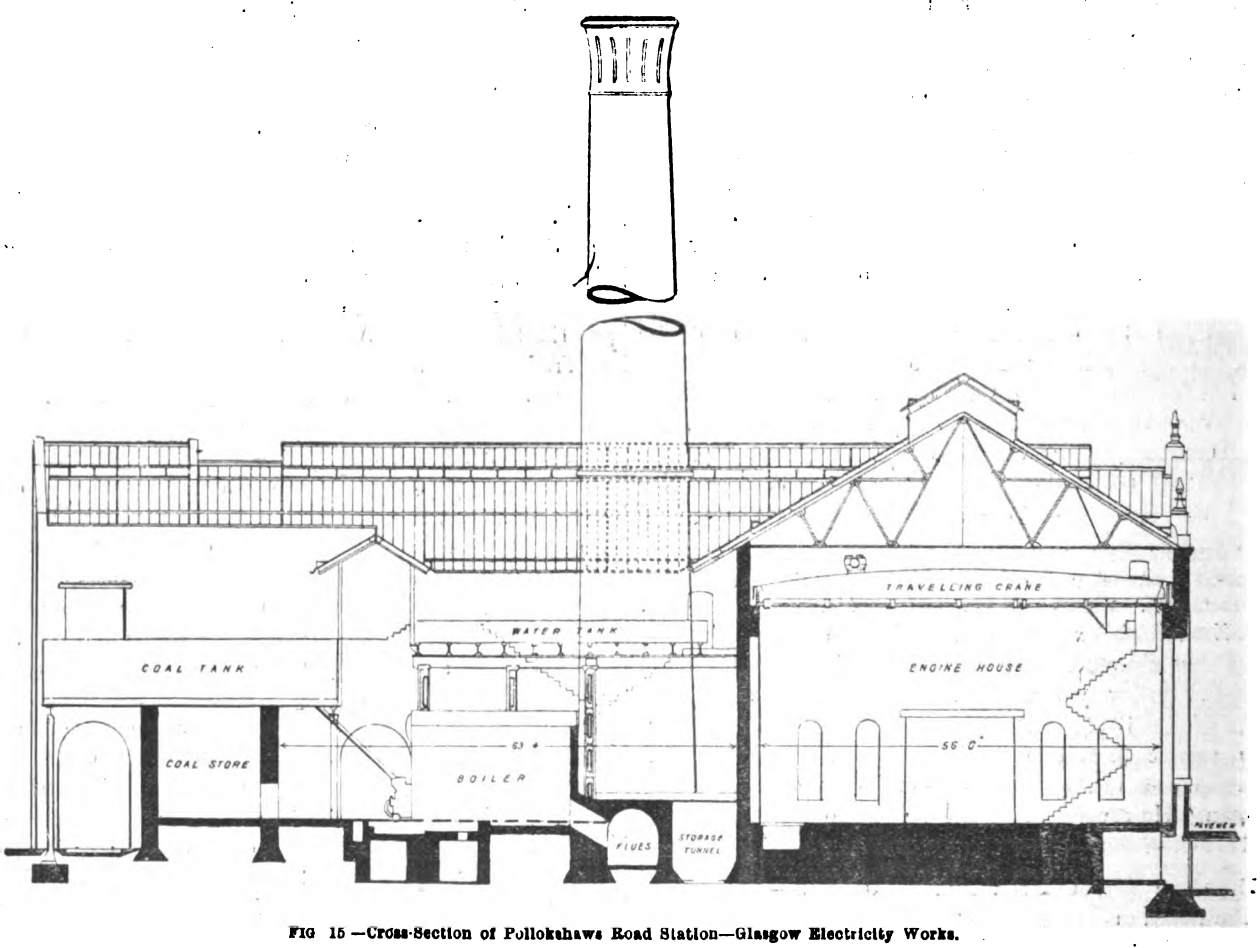

FIG 15.—Cross-Section of Pollokshaws Road Station—Glasgow Electricity Works.

Unlike the Port Dundas station, the St. Andrew's Cross station is situated alongside a railway siding instead of a canal, and this fact has necessitated a different method of handling the fuel when it arrives at the works. From the section (Fig. 15), it will be seen that the coal is stored in a large tank over the coal store. Running parallel to the coal store for the entire length of the boiler-room is a

Digitized by Google

tunnel, seen on the extreme left; the railway wagons are shunted into that siding, an entire train at a time, and at the distant end each wagon, which holds from seven to ten tons, is raised by an elevator to the platform seen on the top of the coal-tank, where its contents are tipped into the tank at any convenient point; it is then run along rails to the other end of the boiler-house, where it is lowered on to the siding. By this means the coal is handled with scarcely any labour, and with greater speed than is possible by any other method. As at Port Dundas station, the portion marked coal store is used to hold a reserve of fuel. At the time of our visit the two elevators which are to raise and lower the wagons were being erected. They will be operated by electric motors. Coal is conveyed from the coal-tank direct to the boiler furnaces by chutes, seen in the section (Fig. 15), and practically similar to that shown in the photograph (Fig. 5, p. 413). The boilers are in all respects duplicates of those already described at Port Dundas. The same may be applied to the steam-piping.

The engine-room differs only slightly. There are at present two 400 h.p. Bellis and Morcom engines. They are three-crank compound, of the type now well known to our readers. These are coupled to Crompton bipolar dynamos, and the combination runs at 375 revolutions per minute. Also one Alley and MacLellan tandem compound single-acting engine of 200 h.p., coupled to one of Messrs. Mavor and Coulson's dynamos; the latter has six poles. This set also runs at 375 revolutions per minute. Preparations are being made to receive another unit, a duplicate of the above, while in course of erection is a Willans three-crank triple-expansion engine of 1,500 h.p. coupled to a Crompton 12-pole dynamo, a duplicate of the set already erected at Port Dundas. At the close of the Glasgow Exhibition next autumn two more 1,500-h.p. units will be installed. These will consist of Willans engines, one coupled to a Crompton dynamo, and one to a British Schuckert Company's machine. These two units are first to be exhibited in the machinery section of the coming exhibition, and will supply a portion of the electrical energy required by the exhibitors. The engine-room is spanned by a 25-ton overhead electric crane made by Messrs. Broadbent and Sons, Huddersfield. It is worked by a single motor, and all the motions are operated by leather belting running on fast and loose pulleys. On the extreme left of Fig. 14 will be seen the offices and staff rooms, beyond which are a smiths' and a joiners' shop, enabling all repairs to be carried out on the premises. The switches and switch gear are practically a duplicate of the Port Dundas apparatus, and no further description is necessary.

THE TENDENCY OF MODERN DYNAMO DESIGN.

BY WILLIAM CRAMP.

Just as the modern cycle frame has, from a variety of forms almost innumerable, come down to the now practically universal "diamond," so in the Paris Exhibition of this year there are distinct signs among the Continental makers of the weeding out and casting aside of certain well-known forms of dynamo, and almost universal adoption of a certain shape of frame for a certain output. It is not altogether a matter for congratulation to the English draughtsman that some of the forms apparently considered as "weeds" by the foreign makers are essentially English, and are still being produced largely by English firms. Of course, it is only fair to admit that the number of English exhibits is very small, and hence there is no possibility of comparison between the *actual working* of the English machine and its foreign rival; still, in the matter of form, and, to some extent, of actual over-all dimensions and total weight, the signs of standardisation are very apparent. The analogy to the development of the cycle frame holds good in the matter of weight, for in dynamo construction abroad it is now an all-important feature to reduce the weight of the frame as far as possible, since the cost of carriage is thereby so much lessened. Hence, by the best makers, cast steel is almost universally used for the frames of all machines above about 5 kw., and in many cases cast steel is used for all sizes. The close agreement in over-all dimensions of machines by various makers is in some cases very marked. The following table, in which are given approximate dimensions of four machines of similar type, and nearly the same output and speed, by four different makers, and which were chosen quite at random, serve to show the general agreement in dimensions. The type of machine was similar to Fig. 1, but the height and width are taken over the slide rails.

Machine.	A	B	C	D
Output	15 kw.	15 kw.	14 kw.	14 kw.
Length	4ft. 0in.	3ft. 0in.	4ft. 6in.	3ft. 9in.
Width	2ft. 6in.	2ft. 9in.	2ft. 7½in.	2ft. 5½in.
Height	2ft. 10in.	3ft. 3in.	3ft. 1in.	2ft. 10in.

The only great discrepancy is in the length of the machines. This may be accounted for in many ways. For instance, the position of the pulley on the shaft—*i.e.*, whether it overhangs the bearing or not—the length of the bearings and commutator, the arrangement of end connections, and clearance allowed between them and the oil catcher. Taking into consideration the difference in output, the width and height agree closely, and the weights are all about 1,900lb.

The similarity in dimensions will be found to be quite as clear in machines of larger output. For instance, in 50-kw. machines of the "Schuckert" type, by four different makers, the length did not vary by more than 4 per cent., and the likeness in other respects was quite as striking.

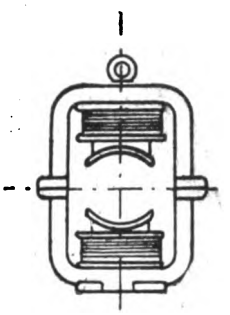

Fig. 1.

Coming, lastly, to the question of "form," we will begin with direct-current machines, and consider the field magnets. Perhaps the first thing that strikes one in the Exhibition is the question, "Where are all the familiar English bipolar machines?" One looks in vain for the standard overtype, for, with the single exception of the Société Gramme, the bipolar as built by all or nearly all the leading English firms practically does not exist. The bipolars that are there (and they are not many) are generally of the form shown in Fig. 1. This form has all the advantages of the Manchester type, with few of its disadvantages. The coils are in the most advantageous position, the leakage is very small, and the machine is practically enclosed. Hence it may be found in the Exhibition in large numbers both as motor and dynamo. The next noticeable fact is the use of the four-pole machine for very small outputs. Doubtless this is partly due to the number of motors now built for 400 volts. Still, in England one is accustomed to find four-pole machines built for an output of over 10 kw. to 15 kw., but in the Paris Exhibition the four-pole type is found in sizes as small as 2 kw., and as a motor even smaller. Indeed, it may be safely said that for almost all sizes the standard field frame is the circular shape, with inwardly projecting radial poles (Fig. 2). Sometimes, as in the case of the Schuckert, this is modified to a polygonal frame. A division, or partial division, of the frame at each pole (Fig. 3) is very common indeed, and no doubt effective in assisting in the best distribution of the flux. Special devices, however, for reducing sparking (such as special pole-tips on one side of a pole) are almost entirely absent, and the only speciality of this kind is the laminated pole-tip with alternate long and short laminations (Fig. 4). As has been already said, the material for the field is almost always cast steel, which gives the machines a very light

Digitized by Google

and neat look when placed beside a cast-iron frame for the same output.

Next, as to the question of armatures. With all the leading firms, both English and foreign, the ring armature is a thing of the past, except for very special uses, such as some tramway generators, where the modified Ayrton-Perry multipolar winding is used. Yet there are two notable exceptions in this way. The Société Gramme and L'Eclairage Electrique have a great number of ring armature machines, and the latter firm build them up to 1,000 kw. The representative of the first-named company at the Exhibition did not express to the writer any conviction that their machines would undergo any alteration in the near future, but the representative of L'Eclairage Electrique said, "We are now beginning to build more drums." It might, therefore, be fairly argued that the majority of

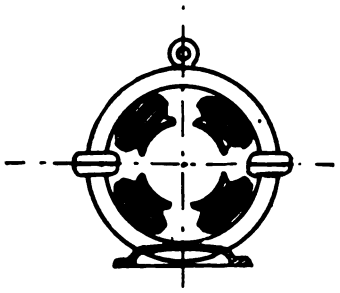

FIG. 2.

FIG. 3.

makers are distinctly against ring armatures. Reasons are fairly obvious. Higher densities, due to shallower stampings, cause greater iron losses, whilst often in bipolars, and always in multipolars, the length of copper required for armature winding is greater, hence greater copper loss in the armature and greater expense. Neither are mechanical reasons wanting for the universal adoption of the drum armature, for the question of shape of spider is more easily and satisfactorily solved in the case of a drum than in that of a ring.

The form of winding that is the favourite abroad is undoubtedly the cylinder winding. This almost follows from the adoption of the multipolar machine, for this method of winding for machines with four or more poles gives a compact and easily arranged set of end connections with economy in copper. It is possible, however, that it makes the over-all length of the machine rather greater than evolute end connectors Still, the contrast between the amount of copper required for ring winding and that required for drum winding becomes all the more pronounced with multipolar machines, and this is another strong reason for the disappearance of the ring armature.

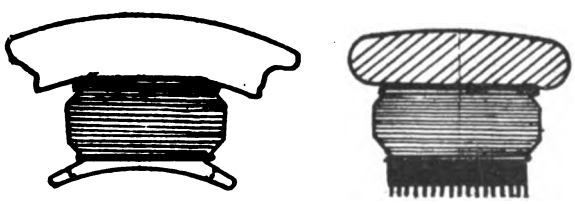

FIG. 4.

Another point which is worthy of remark is the varying length of gap allowed by various makers. The fact that the sparklessness of a machine depends to a large extent on the product of the density in the gap × length of gap seems to induce not a few makers to increase the clearance in their machines, though one would have thought that the advent of cast steel would have made the alternative of increasing the gap-density more natural and quite sufficient. Of the forms of stampings that are being used, the "toothed" and "slotted" are very much to the front—indeed, for all sizes of machines abroad they are the rule, and the smooth core is quite an exception. The shape of tooth is for all larger machines almost invariably like that sketched in Fig. 5, with an insulating strip driven in at the top as shown.

Leaving, now, the direct-current machine and coming to the question of alternators, we find what is generally known as the "iron-type" alternator absolutely universal. There does not seem to be throughout the whole of the Exhibition one single instance of an alternator of the "copper type." By "copper" type, of course, is meant that type of alternator in which the armature contains no iron, such as the disc machines of Siemens, Ferranti, and Mordey. Of course, one must again remember that the English exhibits are comparatively few; still here is a common form of English machine which is regarded with so little favour by foreign firms that not one of its class is to be seen. This may be due to several good reasons: firstly, most of the large alternators shown are three-phase, and the disc machine does not lend itself well to polyphase winding; secondly, it is doubtful whether the copper-type machine is so good mechanically as the iron-type machine; thirdly, machines with a certain amount of iron in their armatures are more easy to parallel than those without iron. The form of these iron machines varies but little. They are

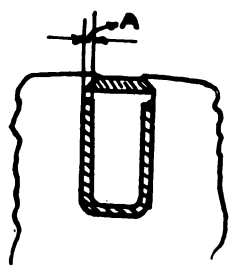

FIG. 5.

all of the flywheel type, and in nearly all cases it is the field that revolves. This, of course, obviates high-tension sliding contacts, and is good from that point of view. A form of machine, however, which is coming apparently fast to the front is the umbrella type—*i.e.*, the machine which has the revolving field magnets outside the armature, but projecting radially inwards from the extended flywheel rim. The advantages of this form of wheel are that the centrifugal force of the field tends to bed the pole down to the rim and to keep the winding well back from the armature, instead of throwing the whole strain on a couple of bolt-heads and tending to throw the field winding towards the armature face. The disadvantage is that the wheel is almost bound to run "cat-necked"—*i.e.*, with a supporting bearing on one side only—for the second bearing is awkward to arrange in the centre of the armature frame.

With regard to alternator details, the shape of pole-face is universally rectangular, but the thickness varies from $\frac{3}{8}$in. up to 3in. (Kolben). The form of the pole itself is usually rectangular, though sometimes round. The winding is almost always a flat copper strip wound on edge, and hence it follows that if the pole is rectangular the strip must stand some distance over the end (as shown in Fig. 6), and this is

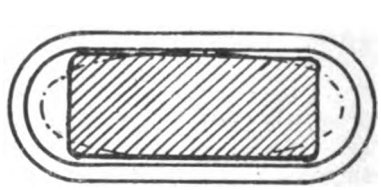

FIG. 6.

frequently seen. The Oerlikon Company, for instance, wind their fields in this way. It seems a most uneconomical arrangement, though possibly it secures rather better magnetic distribution. Surely the better form is the elliptical pole with rectangular face (as shown dotted in Fig. 6), for it is obvious that with the same amount of steel in the pole itself the length of copper will be less and quite as easy to wind.

Laminated pole-faces are fairly usual, though not universal, and in some smaller machines the field magnets are laminated throughout—*i.e.*, the magnet will be built up of a number of star-shaped plates, the points of the star forming the poles of the alternator. The armatures of alternators abroad show signs of standardisation. They are nearly always coil windings, lying in large and deep slots, which are sometimes arranged so that the coil may be wound on a former and slipped into place, and sometimes so that it can only be wound in position. The

Digitized by Google

first of these two methods may be used with a tooth of the shape of that shown in Fig. 5, where it will be seen that the projecting part of the tooth is just equal to the slot insulation, A. Both methods of winding are, however, practised, and not infrequently both are used by the same firm.

There are certain differences in the schemes of winding adopted by different firms. Some prefer windings which may be divided and packed in segments, whilst others arrange their stampings so that they overlap. The latter arrangement seems to have the effect of making the machine run more silently, and it must be said that throughout the Exhibition these large iron alternators do run with very little hum.

Most of the better-known firms are building inductors for special purposes, such as very high speeds, but they do not specially support or recommend them. The fact is that there is a general feeling throughout the Exhibition that plants of 1,000 h.p. or 1,500 h.p. are best running at a speed of about 90 to 100 revolutions per minute, and there are few serious attempts made to construct plants of the combined high-speed order, such as those at Bristol (Ferranti - Willans), Sheffield (Raworth - Mordey), or Plymouth (Ferranti). Whether they are right in this or not time will show, for the battle of the high *v.* low speed engine is not finished yet. Still, it is necessary to keep a sharp look out as to what are the tendencies abroad, for it is not pleasant to recollect that in at least two large central stations in England, where up to the present English machines have been used, a Swiss firm have the order for extensions of plant.

HIGH-SPEED RECIPROCATING ENGINES.*

BY ALLAN COATS, B.SC.

The study of high-speed engines is a fascinating one, and the points of difference between them and their slow-speed brethren are many and interesting. The history of the introduction of high-speed engines is analogous in many points to that of the safety bicycle. In the case of the bicycle the "safety" was introduced because people considered that being flung on the ground several times a year from a height of, say, 5ft. and at the rate of 10 miles an hour was monotonous; the machine itself was regarded as slower, uglier, and inferior in every way. In the case of the high-speed engine it was introduced on account of the necessity in confined spaces of driving dynamos direct, and was, as a rule, only employed where a slow-speed one could not be used. High-speed engines were decried on all sides as steam-eaters, and liable to breakdown, till the genius of one Peter William Willans placed them on their true basis, and proved conclusively that high rotating speed was one of the chief elements of economy. It is not to be wondered at that the early high-speed engines were liable to breakdown; the conditions were so novel, and the effects of inertia and reversal of stress hardly received the amount of attention they require, but there is no reason to doubt that the high-speed engine of to-day is second to none in economy, freedom from wear, and reliability. It is not surprising that this engine is more and more coming into use, not only for electric purposes, but for mill driving as well. To take a common instance from mill practice, we have a slow-running engine with large flywheel sometimes measuring 35ft. in diameter driving smaller pulleys in the rope-race. Would it not be much better to have the driving and driven pulleys about the same size and speed up the engine? Or, to carry the principle still further, we might do away with the large engine-house, make the rope-race the engine-house, and have a separate high-speed engine for each main shaft. In this case it would be impossible for all the engines to break down at once, and even supposing one engine gave way, all that would be required would be to have spare pulleys on each shaft, and connect to the shaft above or below, or possibly both. There are a great many points of difference in the manufacture of the two types. For instance, in lining up, a slow-speed engine might be a good deal out and one never know it, but the same amount would be fatal to the high-speed one; it must be practically dead in line. The reason for this is that any want of alignment sets the reciprocating parts vibrating sideways, and as all these inertia effects increase as the square of the revolutions, the strains are 100 times greater at 10 revolutions per second than those at one revolution per second, and the result is a side knock on the connecting rod that no system of lubrication can prevent. In order to assist the engine to take up its proper aligument when working, it is almost necessary to have floating packing, or very deep packing for the piston rods, especially if the engine is of any considerable size. These causes even affect the shaft journal. If it is not quite round, power is lost in lifting crankshaft flywheel every revolution. In two-crank and single-crank engines it is advisable to balance the whole of the connecting rod and cross-head with, of course, the crank webs. This produces a greater horizontal vibration, but the total vibration is very much reduced.

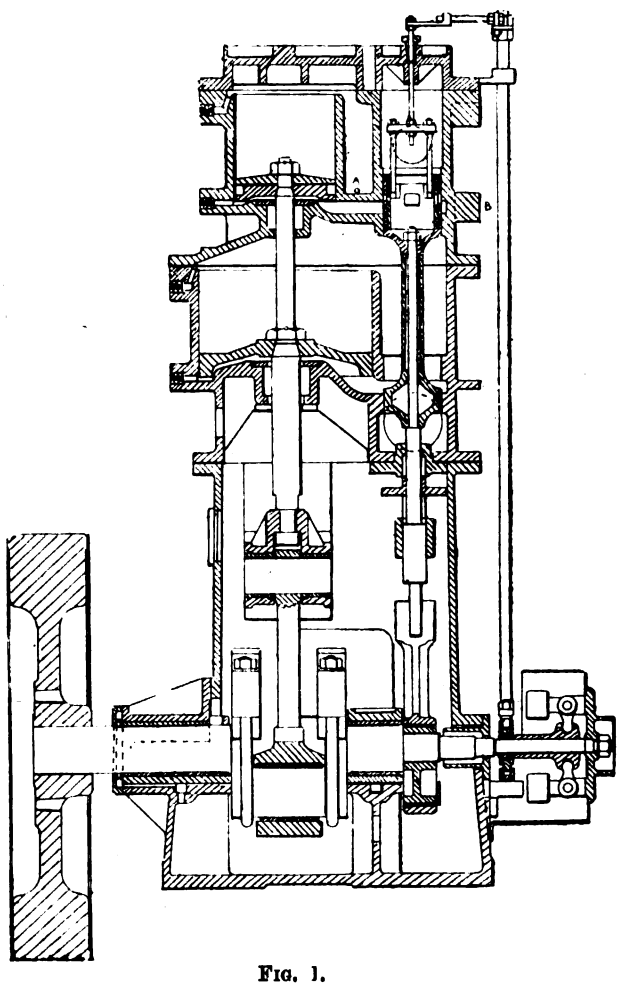

FIG. 1.

I should like now to direct your attention to some matters of detail, and, firstly, I wish to make a few remarks on piston packings. I have recently designed an engine which was extremely favourable for the observing of piston packings (Fig. 1). The space above the high-pressure piston in this case acted as a steam buffer, and was only connected to the live steam by a small non-return valve, which kept up the supply. The engine was sometimes worked with the top cover off, a small cover being temporarily put over the valve chest. In this piston, not only could the exact amount of leakage be observed by means of the indicator card, but as there were holes bored in the junk ring it was possible to see whether the steam was escaping past the vertical face or past the horizontal faces of the rings by putting on the cover on valve chest, and running the engine double-acting without the steam buffer; if the steam escaped up the sides of the piston it was passing the vertical face, if it came through the holes in the junk rings it was passing the horizontal faces. The rings used were Willans type—*i.e.*, an inside spring ring and two outside ones. Now, even at very moderate pressures, say 20lb. to 30lb., steam escaped

* Paper read before Glasgow Technical College Scientific Society.

Digitized by Google

freely through the junk ring holes, even though the rings had been bedded down and were a nice pushing fit in the pistons; these holes were afterwards plugged up. This proved that steam finds its way pretty easily to the back of most piston rings.

Leakage of Piston.—Again, it was observed that the piston, which was fairly tight before the engine started—*i.e.*, with steam on and engine at dead centres—leaked very badly after starting, and that even when stopped and brought to the dead centre and steam turned on again, the leakage of steam was enormous, as could be seen by opening the indicator and lubricator cocks. Suspecting that the rings were being forced from the face of the cylinder by water and oil, I caused a small piece of flat brass to be inserted in the joint of the inner spring ring, and this kept it from collapsing. The result was marvellous, as may be seen from the indicator cards (Figs. 2 and 3) taken immediately before and after. This changed the loss from

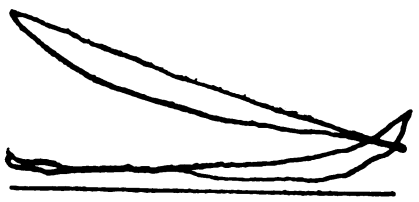

FIG. 2.—Indicator Diagram taken Before Strengthening the Piston Ring Springs

the buffer from about 10 h.p. to rather under 1 h.p. It might be objected that the spring ring was much too weak, but its proportions were based on Willans's practice, and besides, the cylinder and springs assumed a very fine polish after a few days' running. The patentee of a well-known form of piston rings, on being shown the cylinder and rings, expressed surprise that there should be any leakage. Whether or not the spring was too weak, even had it been stronger, through time it would have expanded to the strength it then had. The probable course of events is that the piston rings are first forced from the cylinder face by the film of water; steam then rushes in between the faces and forces the rings in. The piston rod packing rings in this engine were also of the Willans type, consisting of two inner rings of white metal and an outer spring one of phosphor bronze. In order to give the necessary elasticity to the white metal rings, the outer edges were cut half-way through at several points. This packing was steam packed, and gave no trouble from leakage. Solid packing rings are extensively used, and in cases like the Raworth engine, where the cylinder is bound to expand equally in all directions, are almost sure to give satisfaction. The difficulty is to know exactly what diameter to make them, so as not to seize on the one hand and not to let steam pass on the other. Our American cousins make pistol valve rings solid up to at least 12¼in. diameter, and

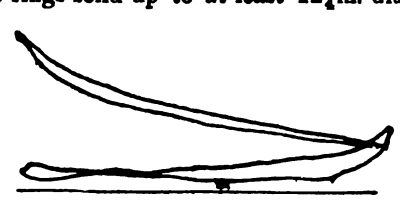

FIG. 3.—Indicator Diagram taken After this Alteration.

it is unlikely that their valve seats remain truly cylindrical. In order to try and get a piston valve which would be tight, and yet not liable to seize, the piston valve in this engine was made with three grooves about ⅛in. wide, and special white metal was run into them and turned down to a nice working fit, the idea being that the white metal would expand more than the iron and wear itself down to the correct diameter. This idea was an afterthought, and, unfortunately, there was not enough metal in the valve to allow of the white metal being sunk more than an eighth part into the cast iron. The result was that, although the rings wore without seizing to their correct diameter, the centre one persistently cracked, although the other two remained all right. The white metal scored more readily than cast iron would have done; but, on the other hand, it left the cylinder faces like mirrors. White metal, however, is very easily chipped in passing over port edges, and it would not be advisable to use it unless there were guide bars across the port.

Port Design.—The correct design of ports becomes more important in high-speed engines, and when we remember that a cylinder is very often filled and emptied in one-tenth a second, it is conceivable that the ports may exercise some influence in the economic result. To secure the best results, it is necessary that the ports should be straight. It is difficult to exactly determine the loss due to bends, but if we take the similar case of the Row tube, used as a condenser, we find that more than twice the amount of steam will be condensed in exactly the same tube after it has been indented. In the same way, in the S ports so common in engines, we have steam at a high temperature and velocity violently thrown against surfaces which immediately before had been as violently swept by comparatively cold steam. Then, again, no attempt is ever made to reduce the velocity of the steam as it enters the cylinder. The result is that steam enters the cylinder at the full velocity of the ports, causing severe currents to be set up and assisting initial condensation. I am sure it would help greatly if ports were belled at the mouth, both vertically and horizontally, and thus reducing the velocity of the incoming steam and assisting the outgoing steam to acquire the necessary velocity. Port losses are nearly always put down to port friction; but this is not so, as the heat generated by the friction is equivalent to the work done on account of the friction and would tend to dry the steam, and thus help the efficiency of the engine, were it not for the second and more serious source of loss caused by the iron storing up this heat and giving it out again to the exhaust. Any increase of clearance caused by widening the port mouth is quite negligible, as large clearances in high-speed engines are fortunately much less harmful than in low-speed ones. This and the striking reduction in initial condensation are both due to the same fact—namely, that the transference of heat from the steam to the cylinder walls is a time function—so that if we run our engine four times as fast we get the same amount of water condensed, but get four times the power—*i.e.*, our condensation per horse-power is a quarter of what it was. Another thing against long and tortuous ports is that the drainage is never so good. This is especially so in high-speed engines, as the time per stroke is so short that there is a tendency for part of the outgoing water meeting the incoming steam and being carried back into the cylinder. The bad effects of water in the cylinder hardly need emphasising, but in high-speed work it is especially important, because, although heat takes an appreciable time to go out and in from iron, on water it acts practically instantaneously, so that high speed does not effect any economy so far as water in the cylinder is concerned. It is, therefore, very important that the drainage should be as perfect as possible. The principal difference in the design of high-speed engines is in the precautions taken to prevent knock and the care bestowed on lubrication.

Single v. Double Acting.—High-speed engines naturally divide themselves into two classes—single and double acting. Double-acting engines are more liable to heat losses than single-acting. In nearly every case one or both of the steam ports has an S bend. The drainage is also very much inferior. Against these disadvantages it had the advantage of getting twice the power out of the same size of engine for the same speed. The turning moment in two-crank engines is not any better than single-acting engines, but in the three crank engines there is an advantage on the side of double-acting.

Lubrication.—The system of lubrication in the two classes is entirely different. The double-acting engine relies on a cushion of oil to keep the parts lubricated, the single-acting on a copious supply of oil and water splashing over all the parts. The forced lubrication is more complicated and liable to break down—in fact, the greatest row I ever heard an engine make in my life was a Belliss in which the forced lubrication had broken down. It was quite impossible to hear oneself speaking anywhere near it. The oil used for forced lubrication after a time gets thick, and it is quite a common thing for the pressure of oil to fall 10lb. in a day; if this were allowed to continue, the lubrication would, of

Digitized by Google

course, fail. On this account oil filters or oil tanks are usually fitted, but, nevertheless, it is well to keep an eye on the pressure gauge occasionally. The oil has also a tendency to heat, both from heat transmitted from the cylinders and on account of the friction of the parts. If we take a 100-h.p. engine, as a rule about 8 h.p. will be lost in friction, of which 60 per cent, according to reliable trials, is lost, apart from piston, piston rod, and valve—*i.e.*, about 4 75 h.p.—and this equals 205 heat units per minute given to the oil. This makes it necessary to have a system of cooling pipes in the bed or oil tank in large engines. Forced lubrication engines have to be made very accurately, or it becomes difficult to keep sufficient oil to prevent knock. On the other hand, if the oil is properly cooled, it is supplied at just the point it is wanted to keep the journals cool. Sea-going engineers have already found out the danger of pouring water on the outside of a hot bearing, as this tends to shrink the outside and cause still worse firing. Splash lubrication has none of the disadvantages mentioned. It is impossible for the system to break down. The oil may be allowed to become very thick without materially affecting the lubrication, especially as the heat soon thins it, and the water prevents the bearings from becoming too warm. If air is allowed free access at top and bottom of the frame, a great amount of heat can be readily taken away. For single-acting engines this system works splendidly, but it is not suitable for double-acting ones. The penetrative power of oil in splash lubrication is remarkable. I have frequently seen it come up past the air buffer and out at the air buffer gland.

Steam v. Air Buffers.—Single-acting engines may be divided into steam buffers and air buffers. Air buffers are designed to absorb the momentum of the reciprocating parts, and keep the connecting rod bush always in contact with the crank pin. Each air buffer is designed for a certain speed, and if that speed be greatly exceeded the buffer is not strong enough and a knock commences. Again, as the lowest pressure cannot be any lower than the atmosphere, and as the pressure rises very rapidly at the end of the stroke if the pressure is carried at all high, it becomes necessary to make the air buffer fairly large in diameter in order to get sufficient pressure at the middle of the curve. Air is also very much more difficult to pack than steam, and any leakage means an absolute loss of power. In an air buffer the piston or cross-head is vibrated from side to side on account of the connecting rod being in constant thrust. This action tends to wear the buffer oval, and there are few single-acting engines which do not suffer considerable loss after some sever or eight years' wear from this cause. Willans made some experiments to determine the effect of water and steam in the buffer of his engine, and found that in each case there was a loss of power as compared with air, but the conditions are very much against the use of steam in the Willans engine, for there we have a large surface splashed by water and oil, so that the loss of heat must have been excessive. Steam buffers removed from the influence of the crank chamber do not show this loss, but on account of Willans's trials the belief is very general that a steam buffer necessarily means loss of power. As this is rather an interesting point, I should like to make it clear that, *apart from radiation*, a steam buffer is as free from loss as an air one. In this connection I would draw attention to the diagrams from Peache's steam buffer. This buffer is between the high and low pressure pistons, and the very slight loss may be easily accounted for by the pistons not being absolutely tight.

The theory put forward to explain the so-called loss in the steam buffer is that heat is absorbed by the buffer walls on the up stroke, and is not given out at the same point on the down stroke—in other words, it lags behind. Now, if you grant what I think are two self-evident statements, I think I can prove my point. These are: (1) that if heat lags behind in coming out of the cylinder walls, it also lags behind in going in; (2) that there is one point in the stroke of the engine at which the steam and buffer walls are at exactly the same temperature. To prove the second statement, it is only necessary to draw approximate curves for the temperatures of the cylinder walls and the steam respectively. Let D B E (Fig. 4) represent the temperatures of the cylinder walls, and A B C those of the enclosed steam—*i.e.*, at the top of the stroke the temperature of the steam is higher than that of the walls, and at the bottom of the stroke lower. As these two curves are perfectly regular, it follows that they cross at some intermediate point, B—*i.e.*, a point at which the steam and cylinder walls are at exactly the same temperature. If now we draw F B G (Fig. 5), a curve to represent the pressures due to compression of an air buffer, and H B K, the pressures due to compression in an *ideal* steam buffer in which at *every point* of the stroke the temperature of the steam and cylinder walls coincided, the point B in the previous figure is the only point on this ideal curve. Starting from this point, then, on the up stroke, and allowing for the lagging behind of the transference of heat, the steam is being compressed and therefore heated; if it did not lose any of its heat to the cylinder walls, it would follow the air curve, F B G; on the other hand, if it immediately parted with enough of its heat to raise the cylinder walls to its own temperature, it would follow the ideal buffer line, H B K. The real action is between these two forming the enclosed loop on account of the steam being at a higher temperature all the time, and, therefore, losing heat. This loop indicates power lost, but on the other side of B the temperature of the cylinder walls is continually higher than that of the steam, and a similar loop is formed, the one loop cancels the other, the net result being the same as the air buffer. In actual engines there is always enough radiation and leakage to

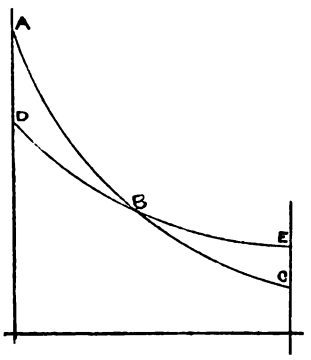

FIG. 4.

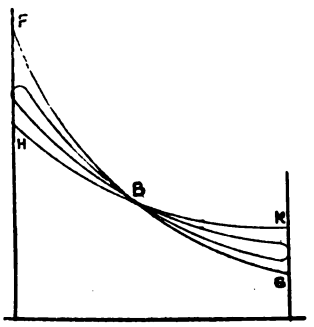

FIG. 5.

prevent the return line of the indicator card from ever crossing the initial line. This radiation in buffers, removed from the influence of the crank chamber, goes either to the atmosphere, in which case it takes the place of the usual radiation from the working steam and tends to keep that steam dry, or it is conducted down the cylinder walls and keeps them dry. In Fig. 1 any steam passing the buffer goes into the high-pressure cylinder, and is not altogether lost. It will always be found, too, that on opening the air-cock of an air buffer that a little steam escapes, showing that the air is very moist. From sheer habit engineers are accustomed to blow through an indicator when indicating an air buffer, thereby filling the buffer with dry air and getting a good card, but a card taken without this unnecessary precaution nearly always shows a loop.

(To be continued.)

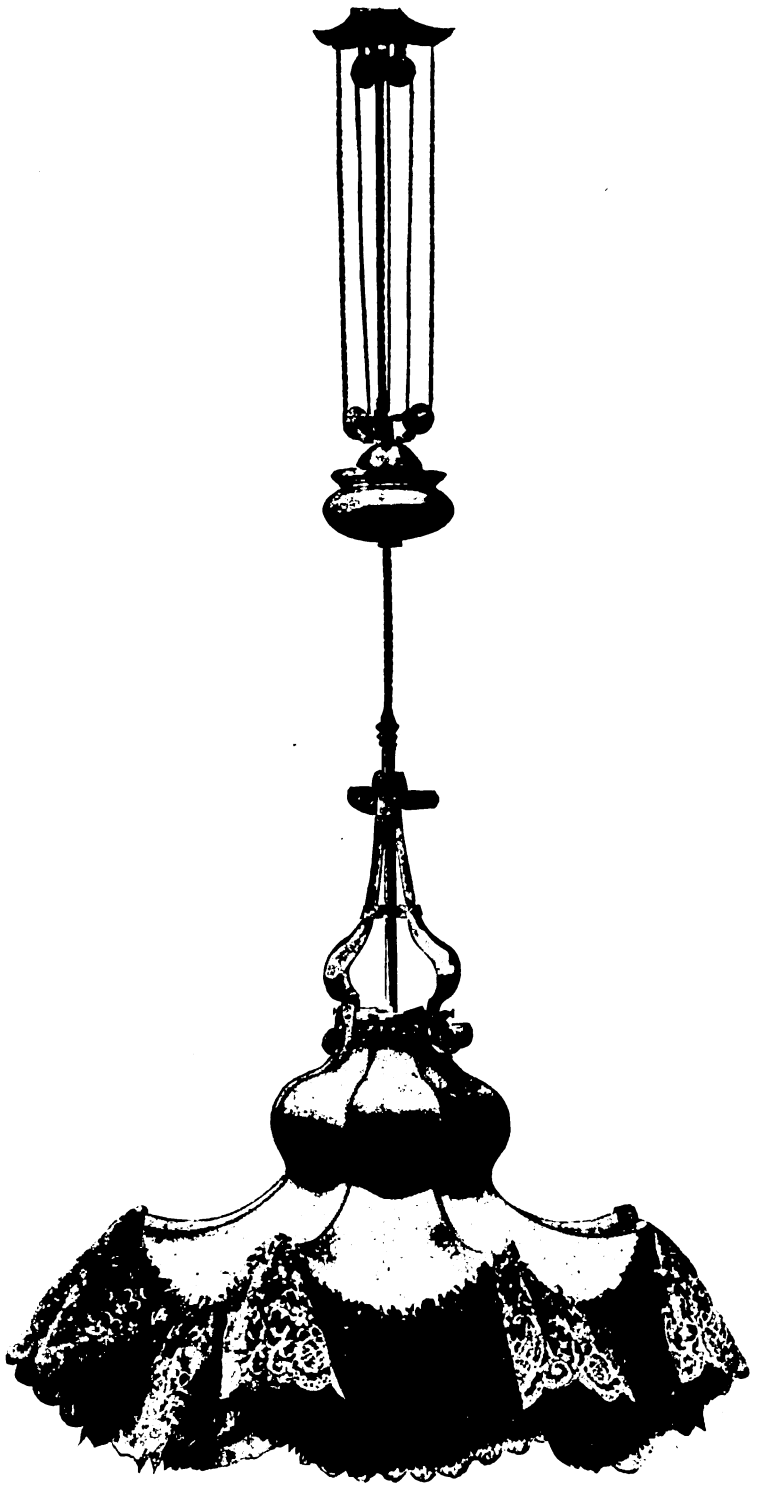
THE ELECTRICAL COMPANY'S NEW SHOWROOMS.

The Electrical Company, Limited, have for many years carried on an extensive business as suppliers of electrical plant and fittings at 122, Charing Cross-road. Owing to the increase in their business in both of the departments—*i.e*, that devoted to arc lamps, incandescent lamps, motors, dynamos, etc., and that which undertakes the supply of electroliers and fittings generally—the company has been obliged to extend their accommodation, and have moved their fittings department to 162, Shaftesbury-avenue. The removal of this department, of course, enables them to devote much more space at Charing Cross-road to heavy goods, and we gather that this space was urgently needed.

The new showrooms at Shaftesbury-avenue have been arranged and equipped by the joint managers of the

Digitized by Google

fittings department. As the building is a new one, and the company agreed to take the ground and the first floor while it was in course of construction, they have had an exceptional advantage in getting the internal arrangements made to their own designs. They are to be highly complimented on the result, and we believe that our congratulations will be accompanied by largely increased returns to the company, owing to the fact that the showrooms as now equipped possess exceptional facilities for the display of electric light fittings. The great idea of their arrangement is that it is not advisable to attempt to display the fittings of various classes in the same room. Neither is it advisable to show electroliers which are to be used in an ordinary-sized room in a large showroom, which dwarfs their general appearance. Another disadvantage of a large showroom is that the wall space is limited, and hence it becomes necessary, in order to show a large number of typical wall brackets, that they should be very much crowded on the same. In this way it is not easy to obtain the lighting effect of an individual fitting. All these objections have been avoided by dividing the space available into a series of moderate-sized rooms, and confining the fittings in each room to distinctive classes. In consequence of the increased wall space the individual fittings are not unduly crowded, and by a series of wall plugs and plug blocks any individual fitting can be lighted alone, so that its effect in a moderate-sized room can be readily seen. The first result is to greatly enhance the appearance of the fittings, while at the same time customers are more easily enabled to make a selection. A long corridor with handsomely draped curtains runs along the full length of the floor, and the small showrooms open out from this. Entering the showroom, the first division is devoted to statuary and to handsome onyx pedestals, on which this statuary can be well displayed. The goods shown here are mostly of large size, as small statuary and groups in brass are displayed in one of the other showrooms. The private office is a large one, and is lighted from one end. Dark blinds for the windows of the room enable the daylight to be excluded, and the room offers every facility for displaying a number of fittings which are designed for use

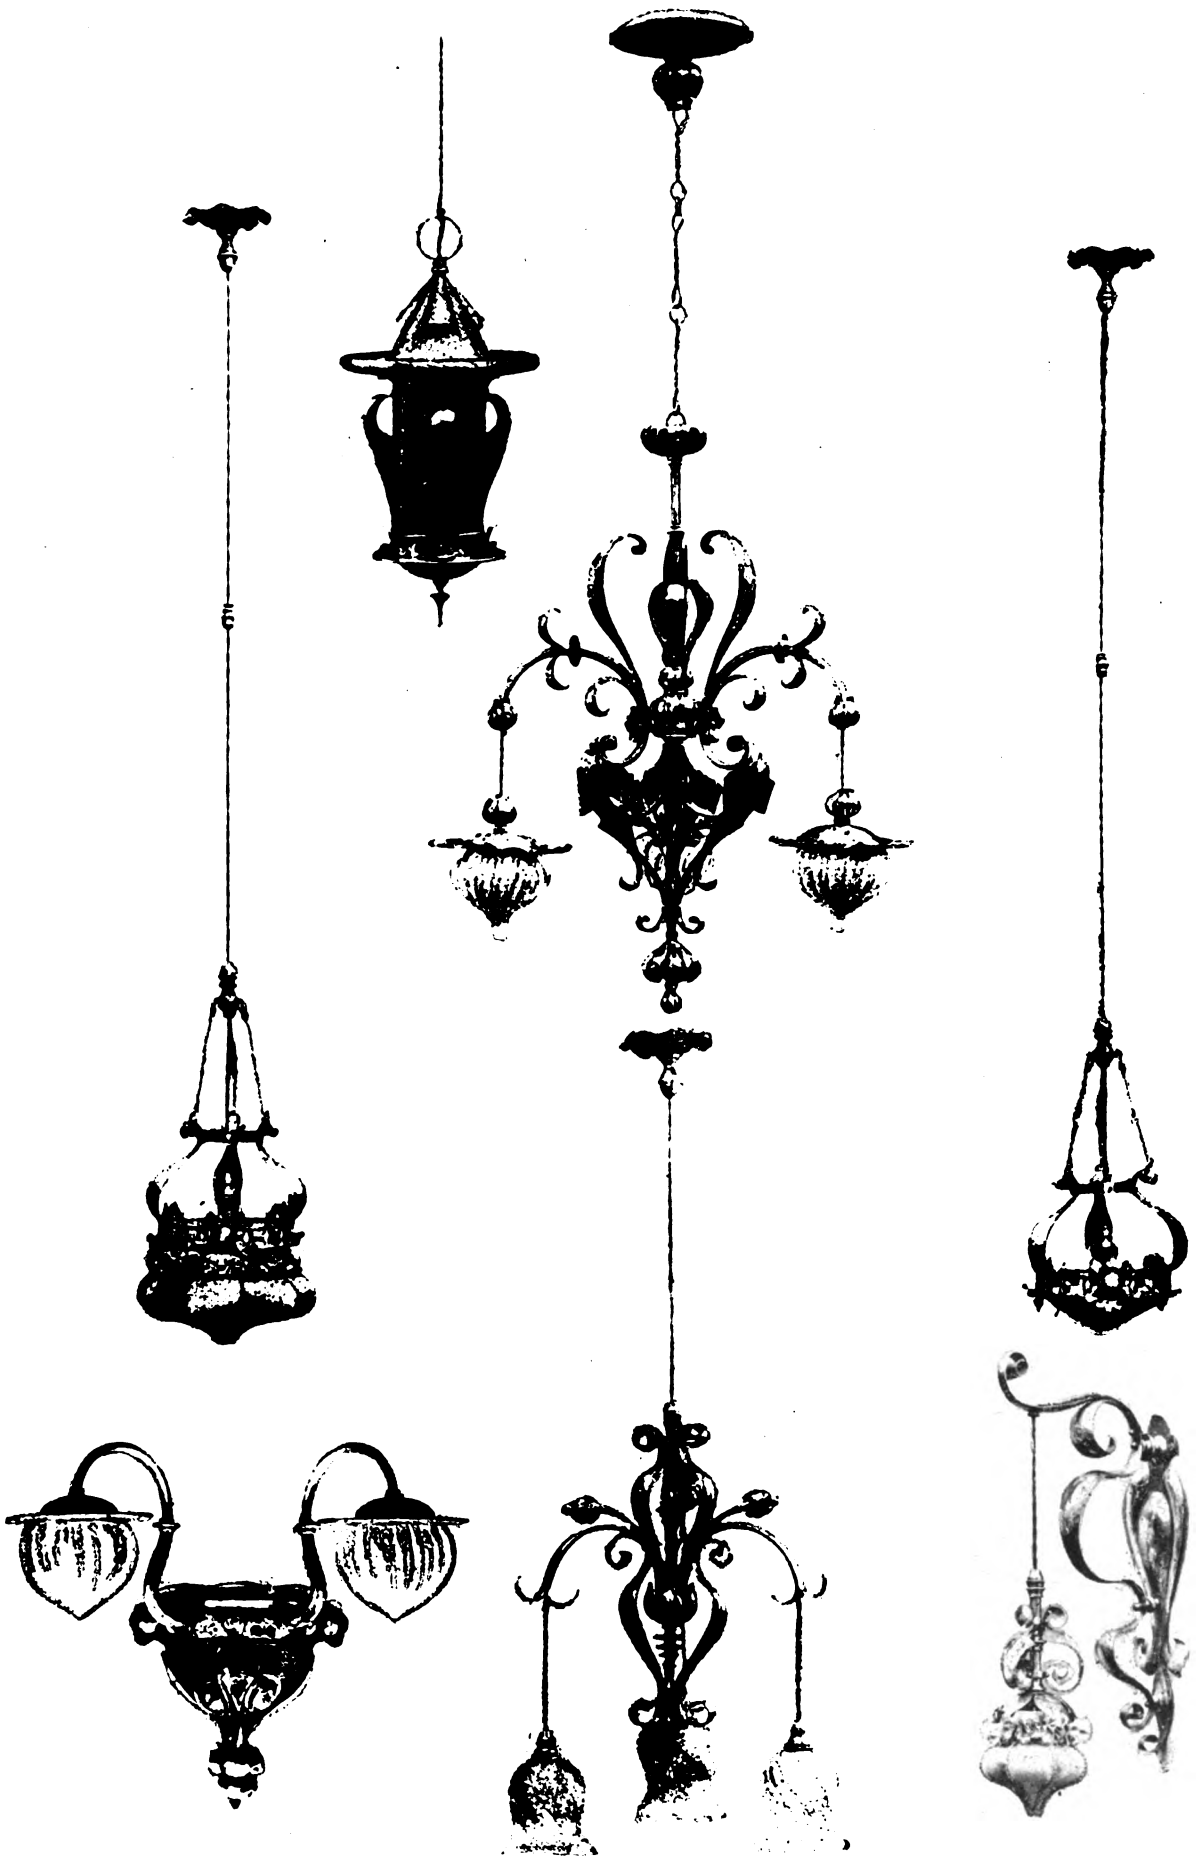


A Dining-Room Pendant.

Digitized by Google

conjointly. Thus, when we inspected it, there was over a large table in the middle of the room a dining-room electrolier of planished steel, while four single-light pendants of similar design were grouped symmetrically round it. On the walls were displayed brackets, also designed to harmonise, and the whole gave a good idea of the adaptability of this planished ironwork for dining-room lighting.

The next department to be inspected is a showroom devoted to oxidised silver fittings, which are especially suitable for use in halls, dining-rooms, libraries, etc.



A Group of Typical Fittings seen in the Electrical Company's Showrooms.

Illustrations of some of these designs are incorporated with this article, but, of course, it is impossible to reproduce the exquisite figuring on some of these oxidised-silver surfaces. A further development of this method of

Digitized by Google

finishing is the reproduction of the surface found on old armour, which can be varied to suit the taste of the purchaser through a range of shades from dark to light. The designs of the wall brackets in this department are novel, and are worthy of a special visit.

The next showroom up the corridor is much longer than its predecessor, and in it are displayed a large series of dining-room pendants and their shades, of all imaginable colours, shapes, and sizes. As they are arranged to be adjustable for height, they can be tried individually by having only the one pendant drawn down lighted, while the rest are raised out of the line of vision. The silk shades on view give a very good idea of the latest in this class of work, while the shapes of the supporting electroliers are extremely graceful. On long benches at the sides of this showroom are displayed bronze and other figures of comparatively small size. Some of the real bronzes on view are exceptionally handsome, and while they are reasonable in price for the work on them, they form a ready means of increasing the cost per lamp of an electric light installation. Just outside in the corridor we noticed some wonderfully handsome onyx pedestals used to support these bronze figures.

The wrought-iron fittings and also the steel fittings of the armour-finished type are displayed in a large room next to the one previously referred to. Here, again, the Electrical Company, Limited, have on view a number of unique designs, and we were particularly struck with some which have been got out for some Freemasons' habitations. They were prepared to meet the views of a well-known architect, who required for the habitation in question an extensive range of wall brackets and many light electroliers. All periods of hammered ironwork are represented in the showroom, and the blackened work is especially suitable in many cases where the oxidised silver would be somewhat too light.

The showroom devoted to French types of electroliers, including the various Louis styles and also fittings of the Empire type, is well filled. Those who are only willing to recognise the orthodox would here find what they required, and would also, we presume, have objections to raise to certain of the goods displayed as being more beautiful than they are correct in style. The ageing effect reproduced on some of these is to the philistine objectionable, and hence the Electrical Company, Limited, have accommodated themselves in certain cases to the public taste. In the last showroom, which is larger than the rest owing to the fact that it runs the full breadth of the building without the breadth of the corridor being taken off, as is the case in the other showrooms, is devoted to the brass fittings of modern types. It is distinctly a commercial room, where the customers who prefer new forms to old can select at will from a great variety of electroliers, wall brackets, and pendants. We were particularly struck in this room with the great variety of glass shades which the company has collected, and which, we were informed, it can supply without delay. The harmonising of the shade and fittings is most essential for the good effect in the lighting of rooms, and in this we think the firm is to be highly congratulated. In all this kind of work it is the individual attention which makes the business successful, and we trust that the attention given to the equipment of these showrooms will be amply repaid by business done. We may add that while the Electrical Company, Limited, only supply to wholesale firms, they are pleased for these firms to bring their clients to these showrooms to make selections.

SPEED ON THE LONDON UNDERGROUNDS.

The opening of the Central London Railway has shown the inhabitants of the Metropolis what can be done by electricity in improving the communication between the suburbs and the City. The first comparison which one naturally makes when using the Central London Railway is on the score of comfort. In this respect it stands far and away beyond the Metropolitan District Railway on account of the purity of the air. Of course, this advantage would not be maintained were the District and Metropolitan Railways to be converted from steam to electric traction, as the open cuttings on these railways would tend to keep the air even more fresh than is the case on the Central London. The fact remains, however, that at the present time a journey on the District Railway is most unpleasant on account of the sulphurous fumes, which, even if they have the healthy properties claimed for them in certain quarters, are by no means agreeable to inhale. A journey on the Central London, on the other hand, is free from any unpleasantness on the score of impure air. There is, of course, the slight smell due to the vitiation of the air by the passengers, but this is hardly noticeable after the first minute. The next ground for comparison between an electric underground railway

constructed on the tube principle and a steam railway running in tunnels, should be made on the score of cost and of upkeep of permanent way. Such comparisons can only fairly be made after a year or two's running, as a certain amount of time is required for items of upkeep to assume their normal proportions. There is, however, one means of comparison which is at once available, and which we have taken the interest to investigate. We refer to the speed obtained on the various London lines, whether driven by electricity or steam. To this end we have had records taken of actual runs on the Central London Railway, the District Railway, and also a few records from the City and South London Railway. We cannot, of course, claim that these figures are absolutely correct, or that they give a fair average of what can be done on any of the lines, but we have discarded any sets of readings which show abnormal length of time on the journey due to the signals being against the trains. We have also compared the running times when the trains are light, such as in the middle of the afternoon, and when they are heavy, as when the people are returning to the suburbs. The accompanying tables give the figures obtained on five separate trials. Underneath each table we have stated the speed of the journey, which is obtained from the total time taken and the total distance covered. The next interesting figure from an engineer's point of view is the average running speed, and it will be seen that, while there is a considerable difference in the first item, in the running speeds the record is borne by a steam locomotive. The following comparisons of the conclusions from the trial in this respect will be of interest, but it must be remembered that the average distance between stations is lowest with the Central London Railway. This distance has a great influence on the average speed.

District	945	14 7	13 3	11·9	10·85
City and South London	920	14 2	—	12·3	—

The next point of interest is the time spent in the stations themselves; and, while this is not an electrical problem, it will be seen that the electrical engineers who had charge of the equipment of both the City and South London Railway and of the more recent Central London Railway have grasped the problem of getting the passengers in and out of the trains more thoroughly than have the steam engineers. Thus it will be seen that when the Central London is running in the afternoon with only about half of its full complement of passengers, the average stop per station is only 11·7 seconds. This time is, however, increased to 20 seconds at times of heavy load, owing to the larger number of passengers which have to get into and out of the trains. The District Railway, on the other hand, stops on the average 33 seconds in each station when running light and 36·8 seconds when running with a large number of passengers. It will be seen from this that on the journey from Uxbridge-road to Mansion House with the same number of stopping points, the District Railway requires three more minutes for stopping at stations. With regular passengers this is equivalent to six minutes per day and to 36 minutes per week of six working days. The value of the time to each of the individual passengers may not at first sight seem to be much, but the waste could be prevented by a better design of rolling-stock. On the City and South London Railway we see the first attempt to

Speed on journey, 12 3 miles per hour; average running speed, 14 2 miles per hour; average stop in station, 23·3; time spent in station, 13 5 per cent. of time on journey; time spent in station, 15 6 per cent. of running time.

Digitized by Google

reduce the time taken in the stations by means of reducing the number of points of ingress or egress in the train, and of placing one conductor at each point. In consequence of this their average stop is only 23·3 seconds. In this connection a few particulars as to the actual arrangements on the Central London Railway will be of interest. In Fig. 1 we reproduce a photograph of the entrances to two of the carriages on the Central London Railway. The gates are shown open, but the gates on the other side are, of course, closed.

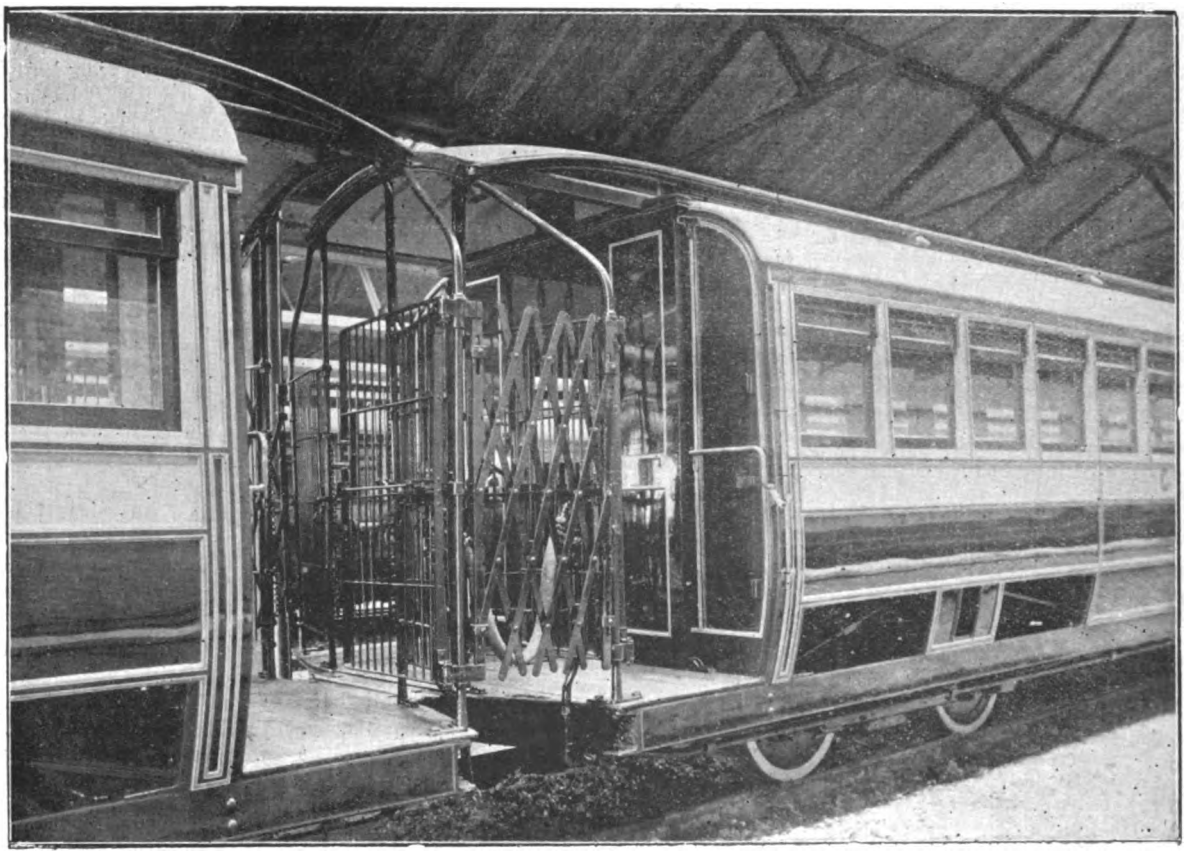

FIG. 1.

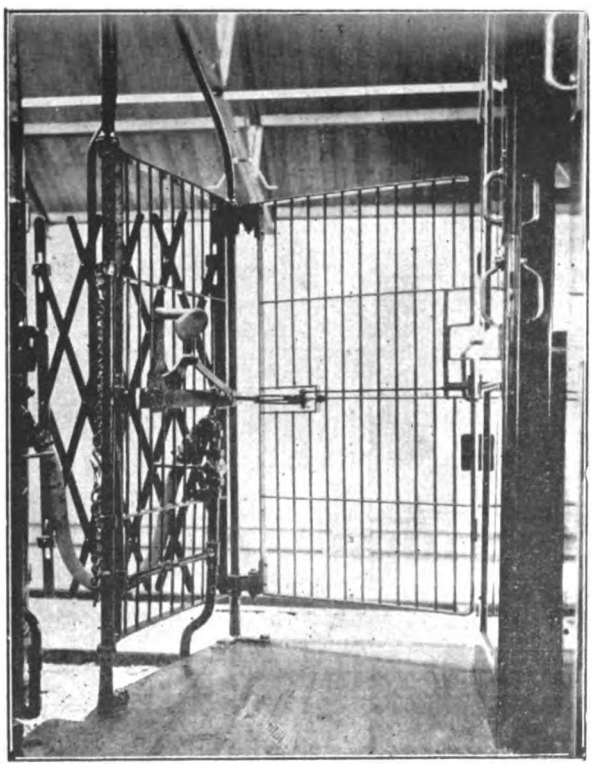

FIG. 2

It will be seen from this and the next illustration (Fig. 2) that these gates are opened and closed by means of levers, which are so placed that the conductor can operate the one gate with his left hand and one with his right. The hinged gates closing outwards have also an advantage from a safety point of view, as passengers trying to board the train while in motion cannot do so. The first element, then, in the shortness of stop is that the gates can be quickly opened and closed. The second element, and in our opinion much more important, is the design of the

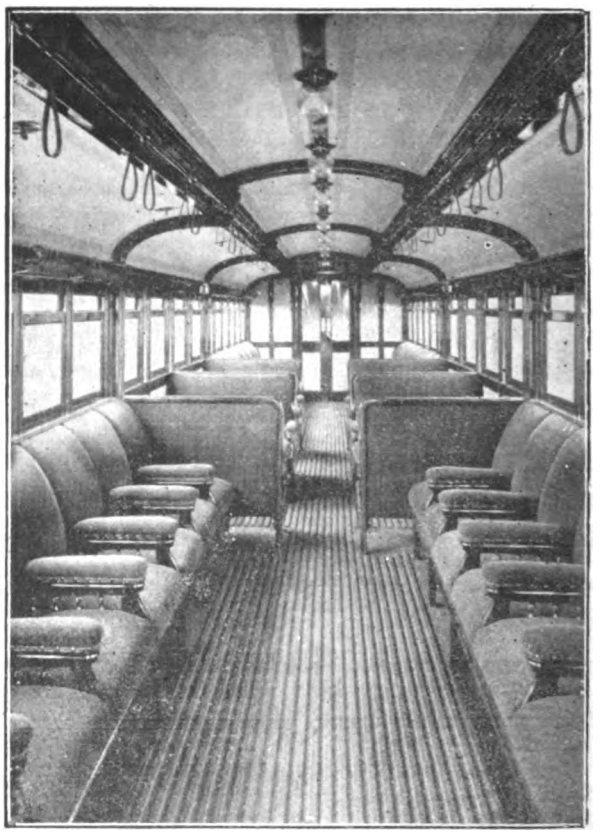

FIG. 3.

seating accommodation in the carriages themselves. Fig. 3 shows a view of this, and we may add that the general arrangements are taken from rolling-stock

Digitized by Google

which has been proved to work successfully on the elevated railways in New York. It will be seen that near the door the seats are placed on either side along the carriage, leaving a broad corridor, in which the passengers collect as the train is being brought to a standstill. In the middle of the carriage the seats are transverse, and hold four passengers in a line across the carriage. Although there is only room for one passenger to pass at a time between these seats, there need be no congestion, as comparatively few people have to use it. A third item in the reduction of the stopping time is the discipline amongst the staff, and the arrangement of calling the name of the next station as the train leaves one station, while as the train is slowing up the conductors also call out the name of the station, which induces the passengers to rise from their seats and collect in the broad gangway. The organisation of the staff is largely due to Mr. C. Aldington, the traffic manager of the line, and he is to be congratulated on the success attained. It must be remembered that there are six conductors on any one train, and that delay on the part of one would keep the whole train back. Perhaps reference should be made to another feature in this saving of time, due to the fact that there is no class distinction on the Central London. It is this hunting for the right class and the closing of the many doors which causes the delay which occurs at the many stations of the District Railway. In conclusion, we have to thank the traffic manager for the permission to take the photographs which we reproduce herewith, and also the British Thomson-Houston Company for the facilities which they have placed at our disposal.

THE "MARY GORDON" ELECTRIC LAUNCH.

This week there was launched from the yard of the Thames Electric and Steam Launch Company, at Strand-on-the-Green, Chiswick, a new electric launch, called the "Mary Gordon," which is designed to accommodate from 65 to 70 people. This launch, which was both designed and built by the company, is to the order of the Leeds Corporation, and will run on the Waterloo Lake, Roundhay Park, Leeds. The dimensions of the boat are: length, 55ft.; beam, 8ft. 6in.; draught, 2ft. 6in; and displacement about 10 tons with full load. The whole of the hull is built of teak, the planking being in narrow widths to allow for expansion and contraction. The cabin is 14ft. long, and the fittings are teak throughout. The cabin is specially designed for this kind of launch, and gives a clear run from stem to stern on a level floor. The accumulators are placed underneath the seats in the fore part of the boat, and are connected up in parallel and series to port and starboard armature and port and starboard field. The motor is designed for marine work, the speed being considerably less than that generally employed on electric launches, but an advantage is gained by the absence of vibration. The motor is in a watertight lead-lined compartment under the floor in the after part of the boat, and connected up direct with the propeller shaft, which drives a gunmetal propeller 24in. in diameter. Incandescent lamps are fixed up in the cabins, and awnings are fitted to the fore and after part of the cabin. The gunmetal steering wheel and the controlling switch are placed forward with two speeds ahead and two astern, and worked with one lever, which can easily be removed, so that the current cannot be switched on by anyone not in charge of the vessel. The whole of the electrical work has been manufactured and completed at the Strand-on-the-Green Works, Chiswick. The "Mary Gordon" is a similar vessel to the "Viscountess Bury," the first electric passenger boat on the Thames with a Board of Trade certificate for 72 people. This latter boat was designed and built by W. S. Sargeant for Messrs. Immisch and Co. in 1888, and which is now running on the Thames at Hampton. The illustrations which we give herewith (Figs. 1 and 2) show the general design of the launch. Fig. 1 is a plan of the same one-half in section, which shows the arrangement of the batteries and also the seating accommodation. Fig. 2 is a sectional elevation of the same boat, from which it will be seen that a very considerable portion of the passengers can be carried under cover. In fact, the cabin is sufficiently large to accommodate them nearly all if some are standing.

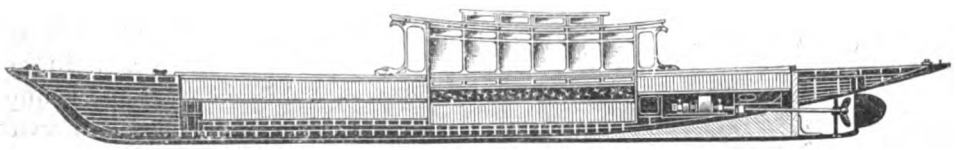

FIG. 2.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTROMAGNETIC INDUCTION.

SIR,—I am disappointed to find Mr. Dunton making such a plausible attempt to cloak the real point of difference between us by drawing the discussion into side issues. His opening remark in your last week's publication is rather beneath contempt, while the remarks which immediately follow it I admit being quite unable to follow in the light of our previous correspondence.

With regard to his further reference to what he erroneously took to be a *non sequitur*, I have already already pointed out that this sentence lends itself, unfortunately, to the misconstruction which Mr. Dunton puts upon it, and were it not for the fact that it is entirely beside the point which is under discussion, he would be justified, perhaps, in making this digression.

In the last paragraph of his letter, Mr. Dunton professes to refer to the real point at issue. All that he does, however, is to link arms with Faraday and others to bolster up his contention. The question is not, however, whether the authority of Faraday is right or wrong on the question of induced currents, but whether or not the statement condemned by Mr. Dunton in Messrs. Slingo and Brooker's text-book is correct. This latter statement in no way whatever contradicts either the laws of Faraday or the remarks quoted by Mr. Dunton from "Dynamo-Electric Machinery." I can only assume that Mr. Dunton's remarks are based on his inability to appreciate the difference between a closed coil moving entirely in a magnetic field and a straight conductor moving in a magnetic field having its ends connected electrically together *outside that field*.

It would be interesting to know, for instance, how Mr. Dunton would explain the action of a simple unipolar dynamo in which an E.M.F. is generated in radial conductors cutting through a continuously uniform field.—

Yours, etc.,
F. JOHNSTON.

Belfast, Oct. 3, 1900.

SPECIFICATIONS.

The drafting of specifications is a fine art, and, as a rule, the progress made in the art by various engineers can be roughly determined by the variation in prices of the tenders received to the specifications. It must be remembered that the interests of the two parties dealing with specifications for electrical engineering plant are in the main the same. The engineer, with whom we must associate his clients, wishes to obtain the best possible plant at its market value as determined by competition. The contractor who tenders on the specification also wishes, for his reputation's sake, to supply the best article in the market, for only by so doing can he hope to establish a business which shall bring in regular returns and good profits. The competition between contracting firms, however, introduces a third element which is the cause of much trouble—that is, that the contractor not only has to conform to the specification with respect to the quality of his work, but also has to do so at a lower price than his competitors. As an engineer who has gone over from the contracting to the consulting side stated, "Contractors are not in business for the good of their health, and have to consider not only that L which signifies self-induction, but also the L which is crossed by two horizontal strokes." Coming now to the question of the effect of the draughtsmanship of a specification on this last quantity, nothing can be more unfair to the contractor than a loosely-drawn specification which has afterwards to be interpreted at the will of the engineer drawing it up. In such a case the contractor has to estimate for risks which he cannot foresee. As a case in point, we know of one corporation which advertised for tenders for the overhead construction for their electric tramways without drawing up any plans for the same. It was left to the individual contractor to supply what he thought was requisite, and on this basis a contract was entered into without any definite position being fixed for the trolley wire. In carrying out the work we believe that the instructions were equally lax; the result was that the position of the rails having been altered, the trolley wire did not come sufficiently near the centre of the rails to meet the engineer's views. The contractor was finally obliged to carry out extensive alterations in the overhead work, which made his contract most unprofitable. The other extreme from a loosely-drawn specification is one in which the details are given to an unnecessary extent, and insisted on being carried out without any valid reason. It should always be open to a contractor to supply goods in conformity to the general requirements of the specification, but with slight variations in detail as can be proved by him to be advantageous in practice. We do not here refer to such large departures from the specifications as necessitate the sending in of alternative tenders, as there can be no objection whatever to this latter course. Passing on from the specification stage to the time when the goods are being delivered, we have to consider how far the interests of the two parties are alike when serious disconformities from the specifi-

Digitized by Google

cation are disclosed by the prescribed tests. Of course, if the goods are better than called for in the specification, the contractor gains in repute, the consulting engineer claims a fair proportion of the kudos, and they remain the best of friends. In certain cases even a bonus passes from the one side to the other, which still further increases the mutual appreciation. The reverse picture is not so pleasant. The dynamo, for instance, discloses a tendency to act as assistant to the heating plant provided in the station, or it may even be that its commutator renders considerable assistance in the lighting of the same. It is then that one hears complaints of the absurdly low limits fixed for the temperature rises, or of the impossibility of designing machines to run with fixed brushes at all loads. Evidence is also brought forward of machines which have for years run without breakdown in spite of the wretched designs to which they were made. In such a case the consulting engineer can either refuse the machine, or can, if so arranged in the specification, take delivery at a reduced price. This latter course is as a rule strongly resisted by the contractor, but we would point out that it is greatly to the ultimate interest of the manufacturers as a whole that such a reduction in price should be insisted upon. The reduction should be such as to represent the value of the machine when judged according to the specification. For instance, if a thousand horse-power dynamo fails to conform with the specification if more than eight hundred horse-power is taken from it, the price should be reduced by 20 per cent. If this course, which is fair both for the buyer and seller, is not insisted on, it becomes quite impossible for manufacturers to tender to specification. The only successful contractor in that case would be one who possessed an intimate knowledge of the extreme variation from the specification which each consulting engineer would allow. He might then for a few years succeed in passing off his geese as swans, but ultimately his workshops would not be distinguishable from scrap heaps on account of the plant returned to him as condemned after a year or two's running; in short, in competitive tendering the rigid enforcement of essentials is to the ultimate advantage of all concerned.

FORTHCOMING EVENTS.

SATURDAY, OCT. 6.

Association of Municipal and County Engineers.—District meeting at East Molesey and Hampton.

MONDAY, OCT. 8.

Poplar Board of Works.—At 4 for 5.30 p.m., opening of new electricity works at Glaucus-street, E.

FRIDAY, OCT. 12.

Electro-Harmonic Society.—At St. James's Hall Restaurant, first smoking concert of season.

RECENT ADVANCES IN WIRELESS TELEGRAPHY.

The following letter from Prof. Fleming appeared in the issue of the *Times* for yesterday:

Sir,—As the subject of wireless telegraphy has not yet apparently lost interest for the general reader, I venture to ask a little space to make known for the first time some recent achievements by Mr. Marconi which have astonished those who have been allowed to examine them. Everyone is aware that in his system of electric wave telegraphy an important feature is the employment of an elevated conductor, which generally takes the form of a wire suspended from a mast. When Mr. Marconi attracted attention by his feat of establishing communication across the Channel without wires, critics raised a not altogether valid argument against its commercial utility, that a wave or signal sent out from one transmitter would affect equally all receivers within its sphere of influence, and hence the privacy of the communication would be destroyed. No one felt the force of this objection more strongly than the distinguished inventor himself, whose original work has caused so many others to attempt to follow in his steps. For the last two years he has not ceased to grapple with the problem of isolating the lines of communication, and success has now rewarded his skill and industry. Technical details must be left to be described by him later on, but meanwhile I may say that he has modified his receiving and transmitting appliances so that they will only respond to each other when properly tuned to sympathy. I am well aware that other inventors have claimed to be able to do the same thing, but I do not fear refutation in saying that no one has given practical proof of possessing a solution of this problem which for a moment can compare with that Mr. Marconi is now in a position to furnish.

These experiments have been conducted between two stations 30 miles apart, one near Poole in Dorset and the other near St. Catherine's in the Isle of Wight. At the present moment there are established at these places Mr. Marconi's latest appliances, so adjusted that each receiver at one station responds only to its corresponding transmitter at the other. During a three days' visit to Poole, Mr. Marconi invited me to apply any test I pleased to satisfy myself of the complete independence of the circuits, and the following are two out of many such tests: two operators at St. Catherine's were instructed to send simultaneously two different wireless messages to Poole, and without delay or mistake the two were correctly recorded and printed down at the same time in Morse signals on the tapes of the two corresponding receivers at Poole.

In this first demonstration each receiver was connected to its own independent aerial wire hung from the same mast. But greater wonders followed. Mr. Marconi placed the receivers at Poole one on the top of the other, and connected them both to one and the same wire about 40ft. in length, attached to a mast. I then asked to have two messages sent at the same moment by the operators at St. Catherine's—one in English and the other in French. Without failure, each receiver at Poole rolled out its paper tape, the message in English perfect on one and that in French on the other. When it is realised that these visible dots and dashes are the results of trains of intermingled electric waves rushing with the speed of light across the intervening 30 miles, caught on one and the same short aerial wire and disentangled and sorted out automatically by the two machines into intelligible messages in different languages, the wonder of it all cannot but strike the mind.

Your space is too valuable to be encroached upon by further details, or else I might mention some marvellous results, exhibited by Mr. Marconi during the same demonstrations, of messages received from a transmitter 30 miles away and recorded by an instrument in a closed room merely by the aid of a zinc cylinder, 4ft. high, placed on a chair. More surprising it is to learn that, whilst these experiments have been proceeding between Poole and St. Catherine's, others have been taking place for the Admiralty between Portsmouth and Portland, these lines of communication intersecting each other; yet so perfect is the independence that nothing done on one circuit now affects the other, unless desired. A corollary of these latest improvements is that the necessity for very high masts is abolished. Mr. Marconi now has established perfect independent wireless telegraphic communication between Poole and St. Catherine's, a distance of 30 miles, by means of a pair of metal cylinders elevated 25ft. or 30ft. above the ground at each place.

I need not enlarge on the possibilities thus opened out

Digitized by Google

for naval and military purposes. The importance of this practical solution of the problem of independent electric wave telegraphy, in which each wireless circuit is as private as one with a wire, is obvious without comment. My desire is solely to mention the above facts for the benefit of general readers, whose minds will thus perhaps be eased of any doubts lest this brilliant application of electrical discoveries should, like some others, fall short in satisfying the requirements of practical use and be relegated to the region of imperfect inventions or unfulfilled hopes.—I am, Sir, yours obediently,

J. A. FLEMING.

University College, London, Sept. 28.

THE EVOLUTION OF SWITCH GEARS FOR HIGH-PRESSURE ALTERNATING CURRENTS.

BY W. E. WARRILOW.

(Continued from page 419.)

The standard high-pressure panel now adopted by Messrs. Ferranti is shown in Fig. 45, where the following modifications will be noticed. The high-tension instruments are supplied with current through a small oil-break fuse, and the spring link of the older boards is replaced by a solid link, bolted on to the 'bus bar fitting and 'bus bar. The bolt holes in the bar fittings and the slots in the links are of such a pitch that the link which will connect the 'bus bar with the panel fitting will also couple two fittings together. An insulated spanner and lifting handle allow of the alteration of the links under current. The synchronising contact is also an improvement on the old solid type. It consists of a brass swing piece pivoted to a small shank, which is sulphured into a recess in a brass casting. This same casting is provided with a curved projection cast on it, around which is wound a spring. A hole in the swing piece is made of the same diameter as the projection on the fitting, so that when the switch is raised to "synchronise," the blades press the swing piece against the spring, thus connecting the incoming machine through a small 'bus bar and oil-break fuse to the synchroniser and its high-tension voltmeter.

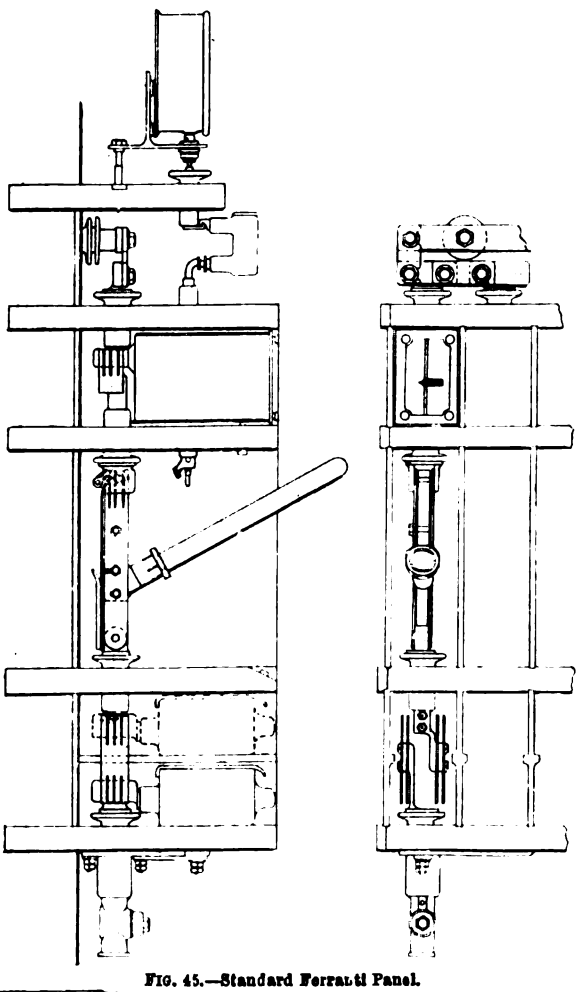

FIG. 45.—Standard Ferranti Panel.

A board, with two inner 'bus bars, erected to the above standard design, is shown by Fig. 46. Below the high-pressure gear will be seen the regulating table, with its handwheels, ammeters, and switches. Beneath the latter four sockets are discernible, and these allow the changing over of the machine field, from an exciter on the alternator shaft to a battery, or *vice versâ*, through a plug switch. The slate on which the field switch is mounted, carries all terminals for the exciter currents, and a bracket to which the field ammeter is fixed in such a way that its scale may be observed through an opening in the upper slate, close to the rheostat handwheel. The rheostat is also an improvement on the older form, it being of the open type, and fixed in the most convenient position procurable, below the regulating table, whence it is operated by the handwheel.

Fig. 47 illustrates two open-type rheostats joined together to form one complete resistance. The single rheostat is, however, generally used, except where the energy to be dissipated exceeds 1,750 watts, when two frames are geared together, as shown. It will be seen that the rheostat is complete in itself, there being no cable connections to separate resistance frames, or sweating sockets, save at the only two terminals needed. The wires are wound on frames provided with stoneware insulating bridges, one set of these being fitted with the stops and terminals. Two such frames are bolted together on one base, the wires of each frame being prevented from touching by spacing pieces at the top and bottom of the rheostat. A slider bridges the stop of the two frames, so that the wires are connected in series. The slider is constructed to bear on the upper and under sides of the stops, which are provided with projections, these tending to keep the connecting bridge firmly in contact with the stops. A screw with coarse pitch operates the slider, so that very little rotation of the handwheel is needed for adjustment of the resistance, and a spring at the upper end of the spindle acts as a damper to the slider when it is brought violently

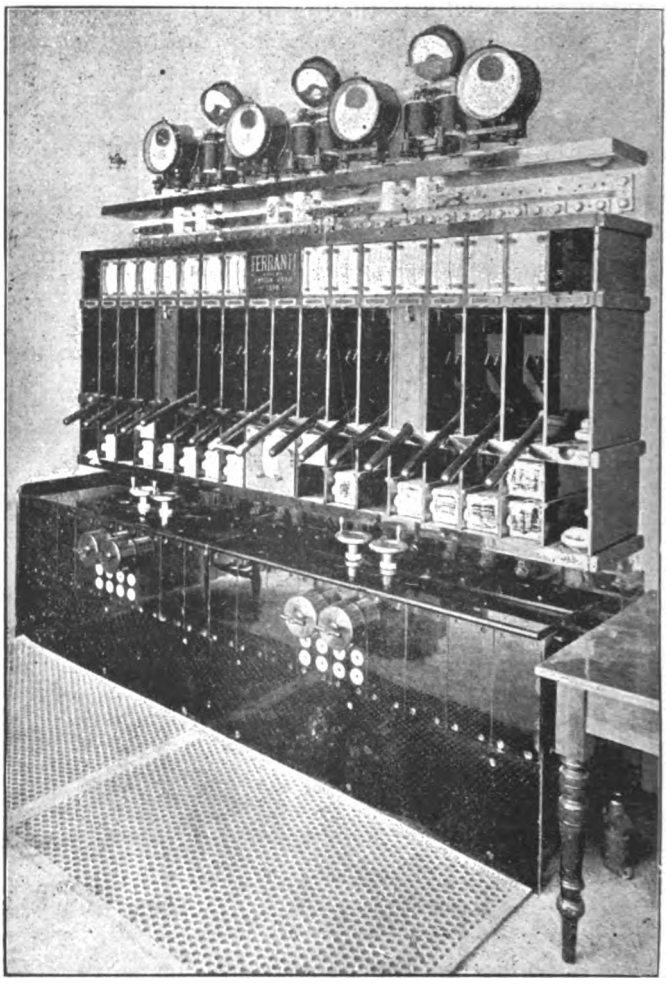

FIG. 46.

Digitized by Google

to either end of its travel. No current passes through the spindle, the slider only acting as part of the circuit. The panels for dealing with currents above 300 amperes are constructed on the same principle in the slate framework as the smaller gears save that the cells are 9in. wide, the

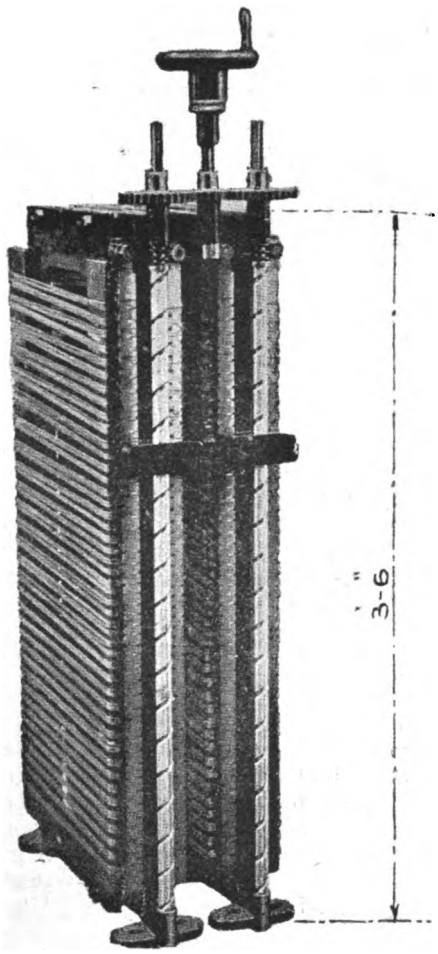

FIG. 47.—Ferranti Rheostat—Open Type.

fittings generally are of large section, and the spring-break switch is replaced by one having an oil break. The principle of this switch will be gathered from Fig. 48, where front and side (sectional) elevations are shown. The moving parts are fastened to a casting, which is bolted to a fitting sulphured into a porcelain insulator on the lower slate. This casting carries an oilpot, O, fitted with gland, G, and a gauge glass, G^1. Through the gland passes a steel rod, R, fitted at one end with a plunger working in a dashpot (to be seen at the base of the switch); a collar, C, is fixed on the rod in the centre, and a final contact piece is screwed in at the upper end. A long polished teak handle operates the blades, B B, which also carry a spindle, P, fitted with a link, L. This link moves, through the medium of an arm A, pivoted to the body of the switch, two other links, L^1 L^1, joined at their upper extremities by a cross-piece, D. The rod, R, passes with clearance through this cross-piece, between which and the end of the plunger on the rod will be seen a powerful spring, S. The switch is shown in the "on" position, when the blades complete the circuit from the casting at the points :a—a: to the fitting fixed in the insulator on the upper slate. A final contact-piece, F, is held in this fitting by a screw, and in this contact the steel rod passes when the switch is closed. In opening the switch the action is as follows: The handle is pulled down, and the blades will leave the upper contact altogether. The rod, R, however, still completes the circuit, it being of sufficient sectional area to carry the full capacity of the switch. In its downward motion the handle causes the blades to move the links, L, A, L^1, L^1, and thus puts the spring, S, in tension by means of the cross-piece, D. The energy thus stored in the spring is applied to the rod through the medium of the plunger, but a catch, C^1, has kept the rod in the upper contact by holding up the collar, C. This catch takes the form of a crank lever pivoted to the switch body, but its horizontal arm carries a spindle passing through a block, M, fixed to the arm, A, and provided with two adjusting nuts, N N. A further descent of the blades compresses the spring, S, until the small block above mentioned bears on the surface of the nuts. At this moment the catch, C^1, is hit off, when the rod, by reason of the spring, S, flies quickly from the upper contact into the oil contained in the pot. The dashpot damps the blow of the rod, which has thus broken the circuit. A small spring, S^1, takes the catch, C^1, back to its place again. It will be noticed that the spring, S, is never in tension until the switch is opened, so that it is not in any way losing its power, even though the circuit be closed for long periods. The final contacts of switch and fitting may be renewed in case of their becoming burned. The synchronising contact differs from the smaller types in that the incoming machine is put on to the synchronising bar through an oil-break fuse of similar make to that used for the instruments. The capacity of panels so fitted is 1,000 kw., there being fuse, switch ammeter, and 'bus bar fittings as in the smaller gears.

Messrs. Ferranti have equipped many stations with standard switch gears of both sizes, but in some cases where replacing old boards some special requirements have been called for by the engineer. The fact that these needs have been met in a most satisfactory manner speaks well for the general flexibility of the design. A switchboard which has been recently erected for the Huddersfield Corporation illustrates this last statement very well. The gear was arranged to meet the requirements of Mr. A. B. Mountain, M.I.E.E., the borough electrical engineer, who originally laid down the station in 1883. The system employed is a single-phase alternating-current one, and the

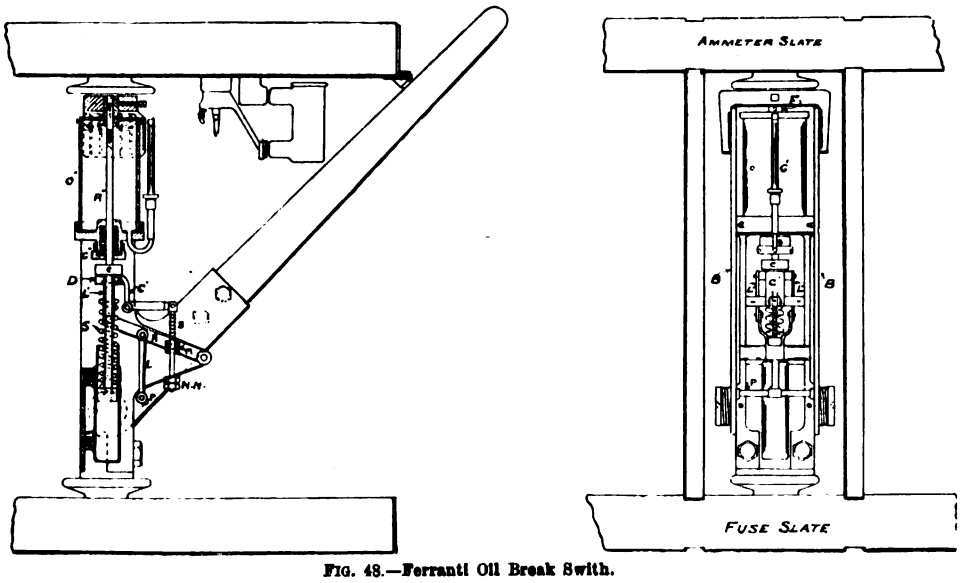

FIG. 48.—Ferranti Oil Break Swith.

Digitized by Google

alternators have been run on separate circuits since the supply was started. The board erected by Messrs. Ferranti differs from their standard design only in the arrangement of the inner 'bus bars, there being three of these instead of one. Fig. 49 is a photograph of the complete board, which comprises a dynamo board (Fig. 50) in the centre and two circuit boards, one on either side of the dynamo gear

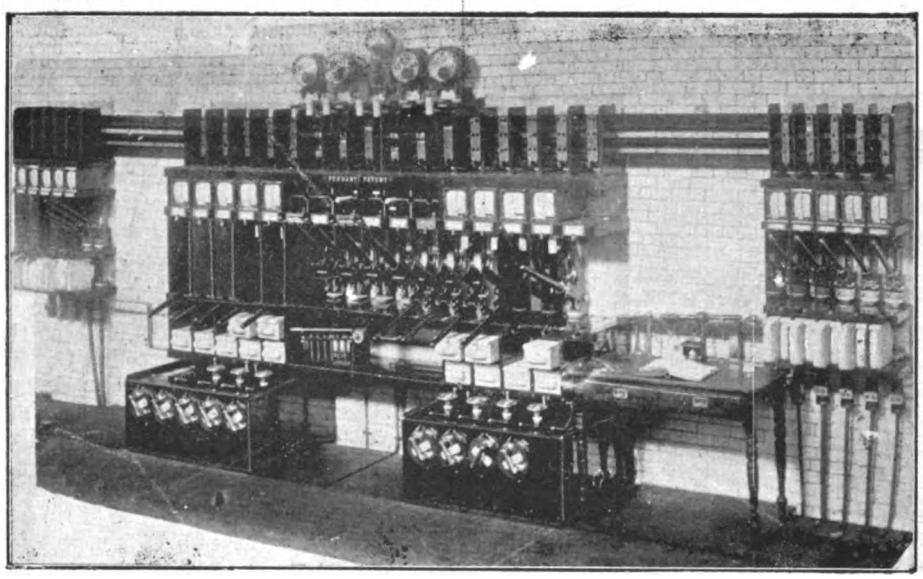

FIG. 49.—Huddersfield Complete Board.

(Fig. 51). These photographs will give an idea of the general arrangement of the board, and the diagram in Fig. 52 will explain the connections of the high-pressure portion. Each dynamo and circuit is provided with a fitting having three holes in it, at centres corresponding to the centres of the three 'bus bars, so that any dynamo can be connected to any one or number of circuits by means of a special expansion plug.

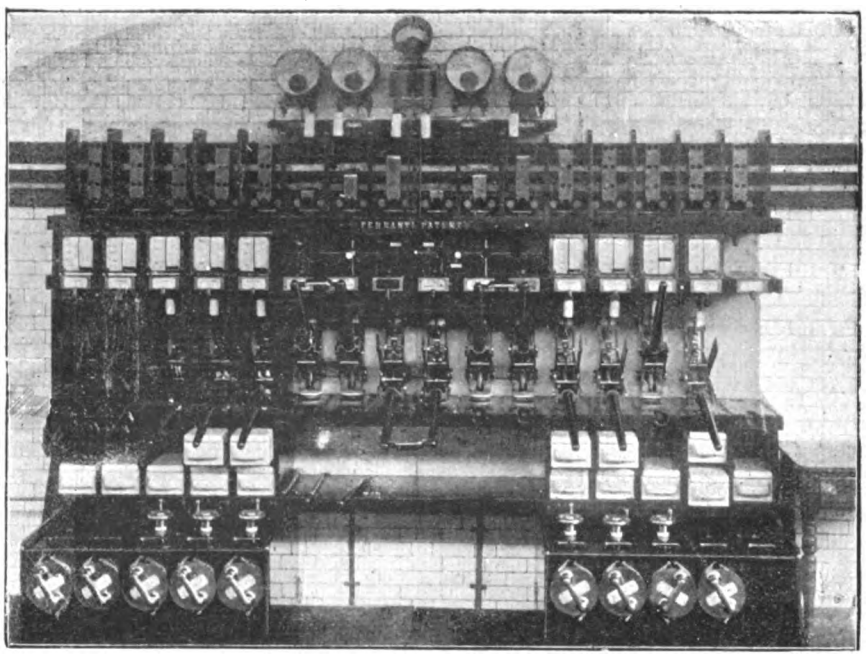

FIG. 50.—Dynamo Board, Huddersfield.

A sectional elevation through the three 'bus bars and fitting shows this plugging device (Fig. 53). The 'bus bars, made up of 2in. by ¼in. copper strip, are mounted on insulators cemented at suitable intervals into the wall. A bar of smaller section is fixed in front of the main bars, and carries sockets for the insertion of the plugs. These sockets are bolted to the bar by small screws, and the bar is fixed to the main laminations by small bolts with spacing washers, over the centres of each vertical slate. A gunmetal casting is bolted to the 'bus bar fitting of each panel, and this casting has three bosses on it corresponding with the sockets on the 'bus bars. Holes 1in. diameter are drilled through these bosses, and the sockets are also bored for a similar diameter. The expanding plug consists of a copper tube tapered from each end towards the centre, and provided with a number of sawcuts in each tapered portion to render the tube flexible at its ends. A brass spindle having a cone (with similar taper to that of tube) turned on it at one end, and being screwed at the other end to receive a travelling cone, is passed through the tube. After the insertion of the spindle in the tube the travelling cone is screwed on, and it is fitted with two pins which travel along the sawcuts and prevent its rotation in the tube. A stop fixed to the spindle behind the moving cone keeps the latter from leaving the tube. After the plug is pushed into its socket, through the boss in the front fitting, it is expanded in place by turning the brass spindle with an insulated handle having a bayonet socket at one end. The rotation of the spindle causes the moving cone to travel inwards by reason of the pins which prevent it turning in the tube. The cone on the spindle also moves towards the centre, and when the handle can no longer be moved the plug has been properly expanded, nor will any efforts to withdraw it be availing until it is contracted by the opposite rotation of the handle. A stop on the

Digitized by Google

copper tube engages with a pin in the face of the 'bus bar fitting, so that when the tube is being expanded it will not rotate in the hole. The handle can be removed when the plug is inserted, so that there are no unsightly projections above the board. Vertical and horizontal guard slates serve to insulate the bars and fitting from one another, besides preserving the panel arrangement in a vertical line

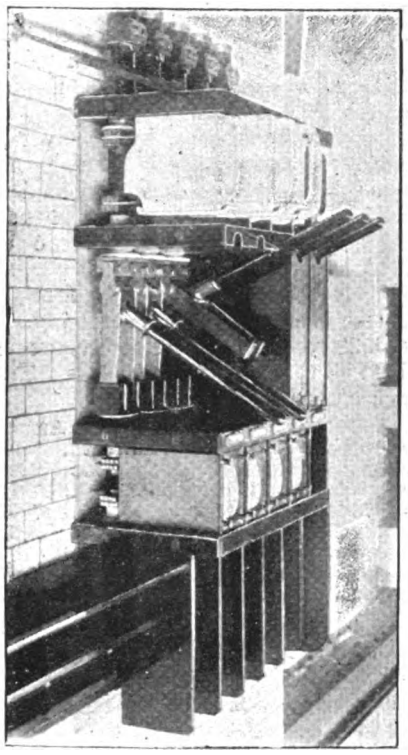

FIG. 51.—One of the Circuit Boards, Huddersfield.

down the board. The slates fit into one another and are thus self-supporting, but several vertical slates may be removed at once for purposes of cleaning and inspection without the horizontal slates altering their position.

Referring again to the diagram (Fig. 52), it will be seen that the board is capable of dealing with 10 dynamos (1,000 kw. each) and 10 circuits (400 kw. each at present, but can be fitted to take 600 kw. each). The dynamo and

plugging to do while the alternators are in parallel. Each machine that has to run during an evening is plugged up on a certain bar with circuits loaded to the capacity of the particular dynamo, and when the time arrives for it to be put in, it is paralleled with the machine already supplying the whole board. The circuits to be fed from the new machine are already plugged up on the correct bar, and when their ammeter readings are obtained on the dynamo ammeter the bar is separated from the rest of the board by opening the interconnector switch. Should this now isolated machine meet with a mishap or breakdown, the circuits which it is feeding may be supplied by another machine without affecting the rest of the board. The bars are paralleled when it is necessary to take off the extra

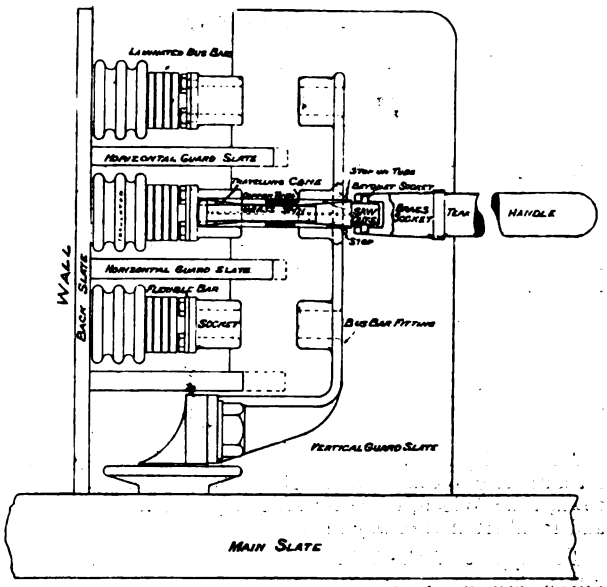

FIG. 53.—Ferranti Expansion Plug and Fittings.

machine, the interconnector switch then remaining closed. It will be noticed that the instruments at the top of the board are very few in number when compared with the machines and bars supplied. The voltmeters, four in number, indicate the pressures on each bar and the incoming machines respectively, and one synchroniser only fills the purpose for paralleling bars together or any machine on to any bar. This is effected by means of a

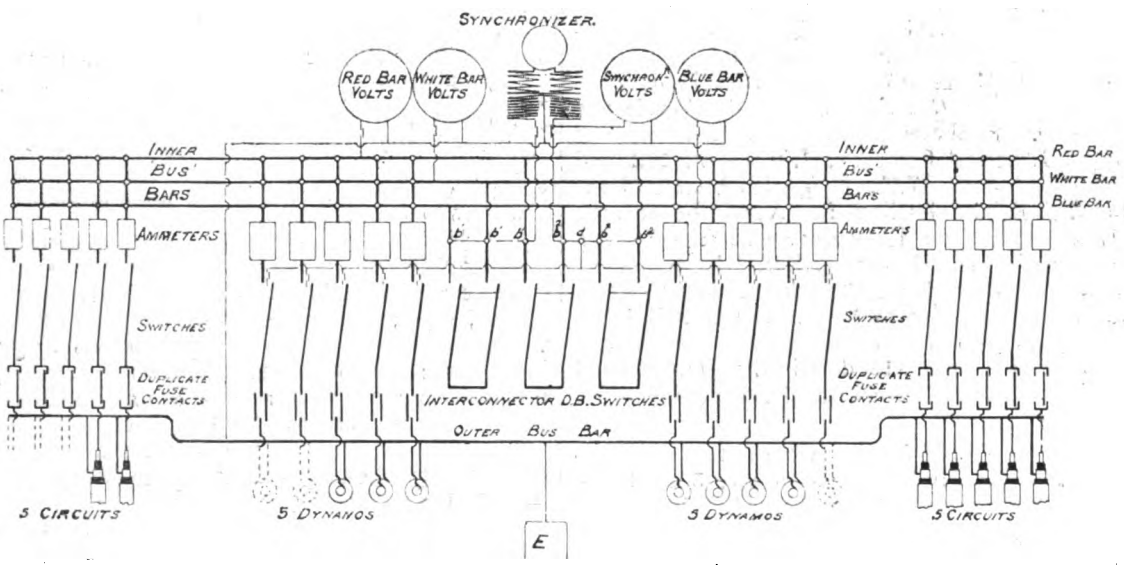

FIG. 52.—Diagram of Connections, Huddersfield Board.

circuit gears are separated from one another by a space of 3ft. 9in., and the arrangement allows of both boards being extended independently up to a certain point. The three inner 'bus bars are coloured, for distinction, red, white, and blue, and they may be all connected together by three interconnector switches in the centre of the dynamo gear. This allows of machines being run separately on one or a number of circuits, and the compactness of the switches renders the operation a very simple one, there being no

plugging arrangement, to be seen in the photograph above the interconnector switches. In the diagram at b^1 b^2 will be seen six sockets, three on either side of the centre of the board, and a seventh at d. These are on two bars, each connected to either limb of the synchroniser by means of a plug. The socket d is coupled to the synchronising bar recessed in the ammeter slate, so that when a machine is run up from rest and paralleled with the board, this socket must be connected through the plug to one limb of

Digitized by Google

the synchroniser, and other limb being supplied through a plug connected to any of the 'bus bars. A guard slate is fixed before each of these synchroniser bars, and it is coloured by a line over each plug hole corresponding to the 'bus bar connected. A locking device prevents the insertion of two plugs on one side, so that the 'bus bars cannot at any time be connected when they have a difference of phase and potential through either synchroniser bar. The connections to the synchroniser and voltmeters are effected by means of bare braided flexible in ebonite tubes, thus avoiding the use of all rubber-covered couplings. The name plates of the interconnectors are coloured to represent the bars which each switch connects, so that mistakes are reduced to a minimum.

(To be continued.)

LIGHT RAILWAYS.

The Light Railway Commissioners will hold an enquiry at the town hall, Kidderminster, on Oct. 17 at 1.45 p.m. into the application which has been made to them by the Kidderminster and District Electric Lighting and Traction Company, Limited, for an order to authorise the Kidderminster and Bewdley light railway.

The Light Railway Commissioners held a public enquiry at Blackburn on Tuesday morning, and decided to recommend the application which had been made to them by the Auxiliary and Light Railways and Tramways Company, Limited, for an order to authorise the construction of the Blackburn, Whalley, and Burnley district light railway.

An enquiry has been opened at Wigan into an application for authority to construct a light railway from Ashton to Newtown, near Wigan, there forming a junction with the Wigan and Pemberton tramway line.

In support of the Witney, Burford, and Andoversford light railway scheme, a public meeting of the inhabitants of Northleach and neighbourhood was held at the institute on Tuesday evening.

A E G. STANDARD-GAUGE ELECTRIC LOCOMOTIVE.

In our issue of Sept. 28 we described the standard-gauge electric locomotive exhibited by the Allgemeine Elektricitäts-Gesellschaft at the Paris Exhibition. This week we are enabled to publish the translation of a report by Inspector Loch, of the Prussian State Railways, on the working costs of an A.E.G. standard-gauge electric locomotive employed for shunting operations in the railway yard at Gleiwitz (Germany). The report in question appeared originally in *Glaser's Annales für Gewerbe und Bauwesen*, and the translation herewith was kindly supplied to us by the Electrical Company, Limited, of 122 and 124, Charing Cross-road, W.C., the British branch of the Allgemeine Elektricitäts-Gesellschaft. As will be seen, the figures given by Inspector Loch prove conclusively that a handsome saving is effected by the electric locomotive as compared with steam working. The locomotive to which the figures refer is of what is known as the A.E.G. 166 type, and the principal differences in construction compared with the locomotive type 115, described in our issue of last week, will be gathered from the following report by Inspector Loch :

The locomotive was built for the overhead trolley system of working, and is of full—that is to say, 3ft. 11in.—gauge, with two axles coupled together, the diameter of wheels being 3ft. 7½in. The distance between the axles is 4ft. 11in., the over-all length between the buffers 17ft. 4½in., width 7ft. 5¾in., and height to the roof 10ft. 6½in. The total weight of the locomotive is 9 tons. The driver cab is roofed in, and is symmetrically arranged in the centre of the locomotive. The free space in front and rear is sheathed, and may serve to store accumulators. The motor is of the V.N.B. 125 type, coupled to the driving axle by means of a double reduction gear of 1 : 5 and 1 : 4·5 ratios respectively, the spindle of the latter gear being mounted direct upon the frame on a level with the driving axles. The motor rests on this spindle by means of two bearings, the other end being suspended on springs from the frame. The motor starters and regulators are mounted inside the cab. The locomotive is provided with a hand brake and compressed-air siren, and is illuminated by electric incandescent lamps. The overhead wire is suspended about 16ft. or 17ft. above the rails, and the current is collected by means of a contact bow, which automatically alters its relative position to the wire when the direction of travel is reversed. The part which comes in contact with the wire was originally made of aluminium in order to subject the wire to as little wear as possible. Experience, however, showed that the aluminium wore away too rapidly, and this was eventually replaced by steel wire, which has proved eminently satisfactory. The locomotive was specified to be fully capable of drawing a load of 100 tons at the rate of 3ft. 3in. per second on a level track, and also to be capable of varying the speed from 2ft. 6in. to 6ft. 6in. per second. A larger variation of speed was, according to the tenders received from the competing firms, not possible unless more than one motor were employed. The supply pressure was 220 volts. The locomotive supplied by the A.E.G. fulfilled all the specified conditions. The results of various tests are tabulated below :

	Amperes.		Volts.
1. Locomotive without load—Starting current...	20	at	210
When running at highest speed	22 24	,,	210
2. Locomotive when pushing or pulling 12 trucks = 78·76 tons—Starting current	70-60	,,	200
At highest speed	40 33	,,	200
3. Locomotive when pulling 16 trucks = 106 56 tons—Starting current	75·70		—
At highest speed	43 50		—

	Feet per sec.
The highest speed attained was—Without load..... ...	7 02
When fully loaded	5 41

It was decided, however, that the speed attained, especially for long distances, was insufficient. The existing gear did, however, not allow an increase in speed without altering the ratio of reduction, and it was therefore decided to increase the pressure in the mains. This was effected by means of a booster, which increased the pressure from 220 to 230 volts. This arrangement has proved very effective, and has been in operation since last October. The results of various tests under the modified conditions are tabulated below :

	Amperes.		Volts.
1. Locomotive without load—Starting current...	55·50	at	310
At highest speed	20 19	,,	310 315
2. Locomotive pulling eight trucks (46·8 tons)—Starting current	60·50	,,	300
At highest speed	30 25	,,	310
3. Locomotive pulling 12 trucks—Starting	60-40	,,	310
At highest speed	26-28	,,	310
4. Locomotive pulling or pushing 18 trucks (106 tons)—Starting	80 60	,,	300
At highest speed	28 35	,,	300·294

	Feet per sec.
Speeds—At no load	11·1
With 25·30 tons	9·2
With 46·8 tons.....	8·37
With 105 tons	6·25

The cost of installation was as follows: for electric locomotive, £400; for overhead line, £700—together, £1,100. In the tender six tons was stated as the weight of the locomotive: the complete locomotive, however, weighs 9 1 tons, so that the correct cost of locomotive may be taken as £500. The overhead line, when extended to all the lines in the yard, will cost an additional £375, so that the total capital outlay will amount to £500 + £700 + £375 = £1,575.

The working expenses of the electric locomotive are as follows: salary for the driver per annum = £77, or per day, 5·13s.; further wages for a shunter, 2·4s.—total per day, 7 53s.

The locomotive works about eight hours a day. Considering the very intermittent service when shunting, the average current consumption is about 16 amperes. Or per day $= \frac{8 \times 16 \times 330}{1{,}000} = 42{\cdot}24$ kilowatt-hours at 1·38d. = 4·65s.; for repairs per quarter (December to February), about 7·5s.; for oil and waste, 11s.—total, 18·5s. If, however, the repairs are taken at 4 per cent. of the capital expenditure

Digitized by Google

$= 0{\cdot}04$, 31,500 = 1,260s.; and for oil and waste, 100s.—total, 1,360s. Then the amount per day is $\frac{1,360}{300} = 4\ 53$s.

The total cost of running the electric locomotive per day is, therefore, 7·53 + 4·65 + 4·53 = 16·71s.—say 16s. 9d. Five per cent. interest on capital $\frac{0\ 05 \times 31,500}{300} = 5\ 25$s., say 5s. 3d. A steam locomotive weighing 31 tons would cost about £1,750.

Running Expenses.—Wages for the driver, 1,580s.; wages for the stoker, 1,280s.—total, 2,860s.; or per day, $\frac{2,860}{300} = 9\ 53$s.

Further shunting allowance and bonus for driver per day, 8 × 0·125 = 1s.; for the stoker, 8 × 0·08 = 0·7s.—total, 1·7s. Wages for shunter per day, 2·4s. Cost of coal per day of eight hours = 150 + 8 × 40 = 470 kg. (1,040lb.), at 9s. 3d. per ton = 4·23s.; for oil and waste, about 13½lb., at 2·2d. = 2 4s.—total, 6·63s.

For repairs and maintenance allow about 0·066 (6·6 per cent.) of the capital expenditure per annum, as found by actual experience during 1898-90—*i.e.*, 0·066 × 35,000 = 2,310s., or $\frac{2,310}{300}$ per day = 7 7s. The total cost per day for a steam locomotive for shunting operations is, therefore, 9 53 + 1·7 + 2·4 + 6·63 + 7·7 = 27 96s.—say 28s.

For depreciation 7 per cent. has to be allowed in the case of a steam locomotive per annum. Or per day $\frac{0{\cdot}07 \times 35,000}{300} = 8{\cdot}17$s.—say 8s. 2d.

To do the work by manual labour would require at least 12 men and a foreman. This would require wages per day 12 × 2·2 + 2 6 = 29s. It will, therefore, be seen that the electric service is by far the cheapest, and that a saving of over 40 per cent. in favour of the electric service has been effected.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

313. When testing an electric locomotive, both in the shop with a brake on the wheels and when pulling a train on the line, what are the quantities which have to be measured? In the latter case, does the draw-bar pull multiplied by the space moved over represent work comparable to the energy supplied to the motors?—P. T.

314. In working shunt-wound motors from a 110-volt circuit nominal, the voltage sometimes drops to 100. If the supply of current is practically unlimited, as from a large generating station, how will this voltage drop affect the working of the motors, electrically and mechanically?—W. G.

ANSWERS.

Question No. 307.—To what extent would the capacity of a compound or shunt machine be affected when working in extremes of temperature, such as are experienced on some ocean liners? Give the ratio.

Best Answer to No. 307 (*awarded* 10s.).—The high temperature of the surrounding air affects a dynamo in two ways: it reduces the terminal voltage by increasing the resistance of the shunt, and thus reducing its exciting power, and it reduces the maximum safe current which the armature can give without damaging its insulation. The latter effect may be dismissed in most cases as of no great importance, for suppose the armature rises 70deg. F. above the surrounding air after a long run at full load, and that the temperature of the room is as much as 120deg. F. (which may occur on board ship), the actual temperature of the winding will be 190deg. F. (or a little more, due to the increased C^2R loss at the higher temperature), and this is insufficient to materially damage ordinary insulation unless kept up for a very prolonged period. Still, the overload safely obtainable from a machine is certainly somewhat reduced when working in the high temperature. On the other hand, the drop in voltage is a serious matter. In the case of a shunt machine wound to only just give its correct voltage of full load in a normal room temperature of, say, 70deg. F., the result of running the machine in a temperature of 120deg. F. would be to increase the resistance of the shunt winding by about ·3 × (120deg. − 70deg.) = 15 per cent. (·3 being approximately the correct percentage increase of resistance per 1deg. F. for copper, allowing for the fact that the temperature rise of the inner layers is considerably higher than that measured by a thermometer on the outer layer of the shunt). This 15 per cent. increase of resistance, and consequent reduction of exciting ampere-turns, will produce a voltage drop of about 8 to 12 per cent., according to the state of saturation of the magnet iron, and this again will reduce the shunt current, which in turn reduces the voltage once more, and so on, until a steady state is again reached with an actual drop in voltage of easily 15 per cent. or more.

In the case of a compound dynamo the effect on the shunt winding is exactly the same as in a simple shunt dynamo, so that the no-load voltage of the machine will be reduced about 15 per cent., as shown above. At full load, however, the drop will be much less than 15 per cent. (probably not more than 5 to 10 per cent.), because the shunt winding only forms a certain proportion of the whole excitation at full load, the rest being series winding, the exciting power of which is not in the least affected by temperature. The effect of the higher temperature on a compound dynamo is therefore not only to lower the voltage at all loads to a greater or less extent, but also to spoil the compounding. Thus, a machine which compounds level in a 70deg. F. room temperature, will compound up 5 to 10 per cent. in a 120deg. F. room temperature.

More exact figures for the different drops cannot be given, because they depend so decidedly both on the point on the saturation curve of the magnet iron at which the machine is working, and also on the shape of this curve. Some of the remedies for these excessive drops due to heating are: (1) the machine should be worked with nearly saturated iron; (2) the magnet winding should be made particularly cool; and (3) a regulating resistance should be kept in the shunt winding of even a compound dynamo, so that as the machine heats up resistance may be cut out by hand, thus keeping the shunt current constant.—Q.

Answer to No. 307 (*awarded* 5s.).—When any dynamo is set to work, the temperature of their masses gradually rises above that of the surrounding air, until, finally, the rate at which the heat is generated is equal to the rate at which it is carried off by radiation, convection, and conduction, when no further rise in temperature will take place. Therefore, the rise in temperature depends essentially upon the amount of cooling surface provided and its actual effectiveness in dissipating heat. So that by the extent of the cooling surface being so proportioned to the watts expended in supplying energy to the field coils and armature, extreme rise in temperature is prevented. In the first place, the higher the temperature the greater will be the loss of energy due to the passage of a given current, for the electrical resistance of copper increases ·21 per cent. per degree F. If, therefore, the temperature be raised from 60deg. to 120deg. F., the increase in the resistance will be 12·6 per cent. of the resistance at 60deg. F. The limits of temperature within which dynamos are worked under average conditions may be taken between 60deg. and 120deg. F., the latter being the ultimate temperature to which the coils attain when continuously worked for many hours together at normal output. Therefore, if the copper on armature rises 60deg. F., its resistance will be increased 12·6 per cent., or R_a hot = R_a cold multiplied by 1·126; so that

Digitized by Google

when a given current is passed through the armature, the loss in volts over its resistance when hot is, of course, increased by the same percentage. In the same way will the heating of the field coils increase the loss of power in them for the same output at the terminals.

But in measuring the temperature it must be remembered that the temperature of the inner layers of the winding is considerably higher than that of those of the surface, and in calculating the resistance of any such coils the average temperature has to be taken as higher than that of the outer layers as measured by a thermometer. The allowance to be made will, of course, vary with the depth of the winding and the closeness with which the coils fit the magnet limbs. For the field-magnet coils of ordinary machines the ratio of the actual increase of resistance to the increase as calculated from the temperature of the surface varies from 1·25 for a depth of winding of ¾in. to 1·5 for a depth of 2½in. to 3in. Thus, if the depth of winding be 2½in. at the temperature at the surface = 55deg. F., the actual increase in the resistance will be ·21 × 55deg. × 1·5 = 17·3 per cent., so that the resistance hot will be increased by an amount equal to 17·3 per cent. of the resistance cold. But now in the case in question the extreme heat is not the consequence of the current passing through the coils beyond certain limits, but due to the temperature of the surrounding air, consequently the average temperature must not always be calculated as explained above. But after the maximum temperature generally allowed for ordinary dynamos has been reached—that is, 120deg. F.—the increase in resistance due to any further rise in temperature should be calculated direct from the temperature of the surface, for the coils will then be almost at the same temperature in every part in consequence of there being no radiation. Then, knowing the increase in resistance per degree F., and, therefore, the lost energy, the ratio of the efficiency at any temperature can be calculated.—J. C. B.

Answer to No. 307 (*awarded* 5*s.*).—The effect of external temperature on the capacity of a dynamo is not above normal, provided the machine has been designed to work in an atmosphere of the given temperature. Provided also that the driving engine is not working to full capacity at normal temperature, and that the field magnets are not saturated at normal speed, a rise in temperature of the surrounding atmosphere to a certain limit will not affect the capacity of the dynamo. The direct electrical effect of temperature on a dynamo is to increase the resistance of the armature and also of the field coils. On the field coils this has the effect of decreasing the ampere-turns and the magnetic flux. If the machine were designed to work in a high temperature, makers would make an allowance in the field coils, such that the resistance of the coils at the maximum temperature and normal voltage would provide normal ampere-turns. If the machine is run in a temperature above its normal, without providing it with increased driving power, its capacity will be affected approximately, as shown by the following example. Take the case of a 30-kw. direct-current shunt-wound machine showing the following tests at full load and normal temperature (temperature of design): output, 100 volts × 300 amperes; external resistance, 0·3333 ohm; resistance of armature, 0·01 ohm; resistance of field coils (in series), 10 ohms; normal temperature, 70deg. F. If such a machine be worked in an atmosphere of 100deg. F., the resistances of the field coils and of the armature, taking the coefficient of copper at 0·38 per cent. per degree Centigrade, or 0·21 per cent. per degree Fahrenheit, will be approximately:

$$\text{Field coils } 10 + \frac{10 \times 0{\cdot}21 \times (100 - 70)}{100} = 10{\cdot}63 \text{ ohms.}$$

$$\text{Armature } 0{\cdot}01 + \frac{0{\cdot}01 \times 0{\cdot}21 \times (100 - 70)}{100} = 0{\cdot}0106 \text{ ohms.}$$

Now if the speed of the dynamo be constant, the voltage will drop approximately in proportion to the ampere-turns of the field coils, which now become diminished, roughly, in the proportion 10·63 : 10, and the voltage of the machine will be 10·63 : 10 : : 100 : 95 (nearly). The new resistance of the total circuit outside 0·3333 + 0·0106 = 0·3439 compared with 0·01 + 0·3333 = 0·3433. This is so small an increase of resistance in the total circuit as to be negligible.

The capacity of the machine may, therefore, be considered to have been affected to the extent of the voltage drop: in this case 5 volts in 100, or 5 per cent. The influence of temperature is really more complex than this, but for practical purposes the effect is nearly as shown. Of course, there would also be certain mechanical losses by working in abnormal air temperature; but this point is not involved in the question.—W. G.

Question No. 308.—In providing condensing plant for a central station, what should be the governing factor in deciding the size of the plant? What is the mistake so often made?

Best Answer to No. 308 (*awarded* 10*s.*).—The wording of this question is somewhat vague, for there are several items which might be termed governing factors, which then can be the governing factor referred to. The aim in all well-conducted stations is to combine efficiency of supply with economy, and these are considered the principal items in attaining the success of the supply. Referring this principle to our question, we have that the governing factor is economy in working consistent with efficiency of supply. In this, the selection of size of condensing plant, as in many other things, no hard-and-fast rule can be laid down which will apply to all cases, and each case must be considered on its own merits; we can, however, select one or two cases to illustrate a principle which may be applied to all.

First, let us consider a station where the maximum load is 1,000 kw. and the average load, or say an all-night load, is 200 kw. In this case it would obviously be unwise to have a condenser or duplicate condensers each capable of dealing with the total of 1,000 kw., or even three condensers that would each deal with 500 kw. of plant, as for a greater portion of the time the 1,000-kw. or 500-kw. condensing plant would have to run for 200 kw., which would result in a loss of economy. In this case the best arrangement would be to have a condenser capable of dealing with the 200 kw. of plant; thus this plant could be run economically for a great number of hours. The selection of the size of the remaining condensing plant required, would depend on the system of condensing employed. The various systems are: (1) surface condensing with air-pump and circulating pump; (1A) surface condensing with air-pump only; (2) jet condensing with air-pump; (3) ejector condensers; (4) evaporative condensers.

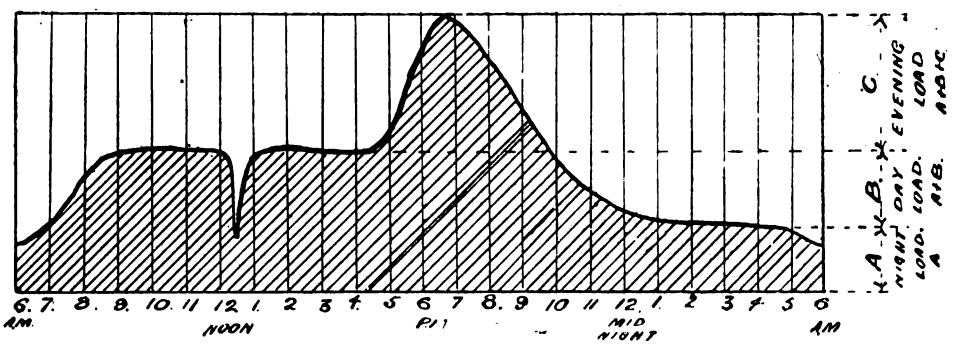
The system to be selected depends on local conditions and the amount of condensing water available. Thus, in the case under consideration, if surface condensers were used, probably two sets of plant, each capable of dealing with 400 kw., would be the best arrangement; with jet condensing apparatus, if a large number of units were used in the station, probably a condenser to deal with every two sets would be best; and with ejector condensers, a condenser for each unit would be advisable.

Let us consider another case, in which the estimated or existing load curve would show three distinct average loads, such as, say, a manufacturing town in which a large number of motors are connected to the mains, also extensive street-lighting which runs throughout the night, besides which there would be the ordinary lighting load, such a load curve would take as an average somewhat of the form shown in the accompanying diagram. It will be seen in this case there are three distinct periods of time in which the plant could be run at its most economical load. The best practice, then, would be to have three condensers, or sets of condensers, which would deal with their respective loads as A, B, and C. From the above cases, and expanding our first definition of the governing factor in selecting the size of condensing plant, we may say it is "the economic ratio of the sizes of condensers to the various average loads"—that is, sizes must be selected whose most economical working load will equal the loads prevailing over certain periods of time. It must not be forgotten to select these sizes with a view to uniformity as far as possible in case of extensions, also in dealing with all possible requirements. With ejector condensers it is considered best to use one condenser with each unit. The mistake most often made is that of selecting condensing plant to deal with a maximum load rather than an average load; thus, though it works economically

Digitized by Google

at the time of such load, yet in most cases that load only exists a short period of the whole time, and at other times an excessively large condenser is being used for a small load—thus loss of economy. It may be pointed out that where air and circulating pumps are used, these pumps, being large enough to cope with the full load of the condenser, will, when the condenser is much too large for its work, be only working at a small percentage of their load, resulting in a further loss, which will make a greater total loss, or, in other words, a lower efficiency. It may be further noted that electrically-driven pumps are far more convenient and economical than steam-driven pumps, on account of their cleanliness, not being so liable to get out of order, and of taking their energy from the switchboard direct from the large economical units.

Another governing factor in this false step lies in the fact that station engineers frequently neglect to consider fuel economy until the lean years of the station's existence have been passed. Condensing plant of suitable size should be provided during those lean years, and the benefit will be felt much more than at a later period. For the purposes of this argument, let us assume typical conditions, taking the load factor of our theoretical station (this load factor being the ratio of average to the maximum rate of production) as 10 per cent., and the maximum load at 400 kw., and the coal consumption during the early years of the station's life at 10lb. of Welsh steam coal per unit. The load factor will, of course, improve as time goes on, and the coal per kilowatt decrease, but in the first years of a lighting station these figures will be found approximately



correct, especially as the coal consumption is a larger proportion of the total costs of production during these first years than it will ever be again. Then it follows that:

1. When condensing plant capable of dealing with the average load over the 24 hours is provided, and granting a 20 per cent. saving due to condensing, the annual amount of saving in our coal bill will be:

$$\frac{400 \times 10 \times 24 \times 365 \times 10 \times 20}{100 \times 2{,}240 \times 100} = 313 \text{ tons per annum.}$$

2. When condensing plant capable of dealing with the full load over two hours per day is provided, and granting, as before, a 20 per cent. saving due to condensing, and allowing only 5lb. of coal per kilowatt generated owing to the rate of production being high and the fuel per unit consequently lower than in the preceding case, the annual amount of saving in our coal bill will be:

$$\frac{400 \times 2 \times 365 \times 5 \times 20}{2{,}240 \times 100} = 130 \text{ tons.}$$

It will thus be clearly seen that the governing factor in the provision of condensing plant should be the average load. The condenser should be provided as early as possible in the station's existence, and should be of such a size that it will deal with the probable average load for the next three years.—F. H. READ.

Other factors in finally deciding the size of plant are: (1) Amount of steam required to be condensed per hour and its pressure. Particulars of the engine or engines, together with the indicator diagrams, to be studied to ascertain these quantities. (2) The average and maximum temperature of the condensing water available. (3) The position of the injection or circulating water supply in relation to the position of the condensers.

In conclusion, it is most important that the full details are gone into most carefully, as a condenser of unsuitable size will not operate so well, and will probably be more costly than one suited to meet the special demands of the case. Makers will often only guarantee results when these particulars are most carefully stated. The advantages of condensing are well known, but these advantages are often minimised by the unsuitable selection of sizes of plant.—E. T. W.

Answer to No. 308 (*awarded* 5s.).—In the provision of condensing plant for central stations, the mistake is often made in providing plant that is capable of dealing with the maximum load instead of only providing sufficient capacity in the condenser to deal with the average load. The capital expenditure on condensing plant for a central station is a considerable item, no matter what system be adopted. The policy of electric lighting stations in this country has almost always been to delay the adoption of condensing plant until the load is large. Then a large amount of capital is expended in providing condensing plant capable of dealing with the top load. This, of course, means that the plant will be run most economically during the two hours of maximum load, but after that will have to be dispensed with owing to the expenditure in running of the condensing plant more than counterbalancing the economy of running the main engines condensing. At the most the condensing plant under these conditions can only be run for three or four hours daily, but in the majority of cases only two hours' economical use can be obtained from it. The result of such a policy is that the capital expenditure on condensing plant remains unproductive during the larger portion of the day. Theoretically, it might be argued that the introduction of such a condensing plant would save the erection of an engine and dynamo, but in practice this has never been carried out. In one case, however, the introduction of such a condensing plant led to the corporation putting in larger dynamos and delaying the installation of a new steam dynamo, but even in this case the difference between the capital expenditure on the condensing plant and new dynamos was not very much less than that on a new steam-driven plant.

ELECTRIC LIGHTING ORDERS.

The report by the Board of Trade respecting the applications to and proceedings of the Board of Trade under the Electric Lighting Acts, 1882 to 1890, during the past year, states that the following applications for provisional orders have been received by the Board of Trade since the date of the last report. The title of order and description of area, name of promoters, and how the application has been dealt with are given in their respective order:

Allerton, Much Woolton, Little Woolton, Childwall, and Garston Electric Lighting Order (amending the Allerton, Woolton, Childwall, and Garston Electric Lighting Order, 1896).—Liverpool District Lighting Company, Limited.—Order granted except in so far as it related to the urban district of Garston.

Banbury Electric Lighting Order (the municipal borough of Banbury).—Electrical Power Distribution Company, Limited.—Order granted.

Barmouth Electric Lighting Order (the urban district of Barmouth).—Urban District Council.—Order granted.

Barnard Castle Electric Lighting Order (the urban district of Barnard Castle).—Northern Counties Electricity Supply Company.—Order granted.

Digitized by Google

Barnet Urban District Council Electric Lighting Order (portion of the urban district of Barnet).—Urban District Council.—Order granted.

Barnstaple Corporation Electric Lighting Order (the borough of Barnstaple).—Corporation.—Order granted.

Basingstoke Electric Lighting Order (the borough of Basingstoke).—Corporation.—Order granted.

Berwick-upon-Tweed Electric Lighting Order (the borough of Berwick-upon-Tweed).—Urban Electric Supply Company, Limited.—Order granted.

Birkenhead Corporation Electric Lighting (Extension) Order. (the townships of Bidston-cum-Ford and Noctorum in the rural district of Wirral).—Corporation.—Order granted.

Bishop Auckland Electric Lighting Order (the urban district of Bishop Auckland).—Urban Electric Supply Company, Limited.—Order granted.

Bonchurch Electric Lighting Order (the parish of Bonchurch, Isle of Wight).—Ventnor Electric Light and Power Company, Limited.—Order granted.

Boston Electric Lighting Order (the municipal borough of Boston).—Corporation.—Order granted.

Brecon Electric Lighting Order (the borough of Brecon).—Corporation.—Order granted.

Bredbury and Romiley Electric Lighting Order (the urban district of Bredbury and Romiley).—Urban District Council.—Order granted.

Bridge of Allan and Dunblane Electric Lighting Order (the burghs of Bridge of Allan and Dunblane).—Urban Electric Supply Company, Limited.—Order granted for the burgh of Dunblane. The two districts applied for do not adjoin, and the Board of Trade refuse to include non-contiguous areas in one order. As the promoters were unable to obtain the consent of the local authority for Bridge of Allan, they elected to proceed with the application in respect of Dunblane only.

Bridlington Electric Lighting Order (the borough of Bridlington).—Corporation.—Order granted.

Brierfield Electric Lighting Order (the urban district of Brierfield).—Urban District Council.—Order granted.

Brierley Hill Electric Lighting Order (the urban district of Brierley Hill).—Urban District Council.—Order granted.

Broughty Ferry Electric Lighting Order (the burgh of Broughty Ferry).—Commissioners of the Burgh.—Order granted.

Caterham Electric Lighting Order (the urban district of Caterham and the parish of Warlingham, in the Godstone rural district).—Urban Electric Supply Company, Limited.—Order granted.

Cheadle and Gatley Electric Lighting Order (the urban district of Cheadle and Gatley).—Urban District Council.—Order granted.

Cheltenham (Extension) Electric Lighting Order (the urban district of Charlton Kings and portions of the rural districts of Cheltenham and Winchcombe).—Corporation of Cheltenham.—Order granted for the urban district of Charlton Kings. As regards the other districts included in the application, the promoters failed to produce the consent of the Cheltenham Rural District Council, or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the order for that district. The promoters obtained the consent of the Winchcombe Rural District Council, but the part of the Winchcombe rural district which was applied for is separated from the remainder of promoters' area of supply by the Cheltenham rural district, and the Board refused, therefore, to include it in the order.

Chester-le-Street Electric Lighting Order (the rural district of Chester-le-Street).—County of Durham Electrical Power Distribution Company, Limited.—The promoters failed to produce the consent of the local authority, or to satisfy the Board of Trade that it should be dispensed with, and the Board refused to grant the order.

Clacton Electric Lighting Order (the urban district of Clacton).—Urban District Council.—Order granted.

Cleckheaton Electric Lighting Order (the urban district of Cleckheaton).—Urban District Council.—Order granted.

Cleethorpes Electric Lighting Order (the urban district of Cleethorpes-with-Thrunscoe).—Urban District Council.—Order granted.

Cobham Electric Lighting Order (the parishes of Cobham and Stoke d'Abernon, in the Epsom rural district, and part of the parish of Byfleet, in the Chertsey rural district).—Cobham Gas Company.—The promoters failed to prove compliance with the requirements of the Electric Lighting Acts and of the rules of the Board of Trade within the time prescribed by the rules, and the Board refused to proceed with the application.

Cowpen Electric Lighting Order (urban district of Cowpen).—Northern Counties Electricity Supply Company.—Order granted.

Dartmouth Electric Lighting Order (the borough of Dartmouth).—Urban Electric Supply Company, Limited.—Order granted.

Egremont Electric Lighting Order (the urban district of Egremont).—Urban District Council.—Order granted.

Elland Electric Lighting Order (the urban district of Elland).—Urban District Council.—Order granted.

Enfield Electric Lighting Order (the urban district of Enfield).—Urban Electric Supply Company, Limited.—The promoters failed to produce the consent of the local authority, or to satisfy the Board of Trade that it should be dispensed with, and the Board refused to grant the order.

Erdington Electric Lighting Order (the urban district of Erdington).—Urban District Council.—Order granted.

Exmouth Electric Lighting Order (the urban district of Exmouth).—Urban District Council.—Order granted.

Farnham Electric Lighting Order (the urban district of Farnham).—Urban District Council.—Order granted.

Felixstowe and Walton Electric Lighting Order (the urban district of Felixstowe and Walton).—Urban District Council.—Order granted.

Freshwater and Totland (I.W.) Electricity Supply Company, Limited, Electric Lighting Order (portion of the rural district of the Isle of Wight).—Freshwater and Totland (I.W.) Electricity Supply Company, Limited.—The local authority refused to consent to the application except on certain conditions. The Board of Trade, for the reasons stated in the special report made by them and presented to Parliament decided to dispense with the consent of the local authority, and granted the order.

Gosforth Electric Lighting Order (the urban district of Gosforth).—Newcastle-upon-Tyne Electric Supply Company, Limited.—Order granted.

Gosport and Alverstoke Electric Lighting Order (portion of the urban district of Gosport and Alverstoke).—Urban District Council.—Order granted.

Grantham Electric Lighting Order (the borough of Grantham).—Urban Electric Supply Company, Limited.—Order granted.

Harrow-on-the-Hill Electric Lighting Order (portion of the urban district of Harrow-on-the-Hill).—Urban District Council.—Order granted.

Hebburn Electric Lighting Order (the urban district of Hebburn).—Urban District Council.—Order granted.

Heston and Isleworth Electric Lighting Order (the urban district of Heston and Isleworth).—Urban District Council.—Order granted.

Hyde Electric Lighting Order (the borough of Hyde).—Corporation.—Order granted.

Hythe Corporation Electric Lighting Order (the borough of Hythe).—Corporation.—Order granted.

Jarrow, Hebburn, and Felling Electric Lighting Order (the municipal borough of Jarrow and the urban districts of Hebburn and Felling).—County of Durham Electrical Power Distribution Company, Limited.—Order granted for Jarrow only. As regards Hebburn, an application was also received from the local authority, to which preference was given by the Board of Trade in accordance with their usual practice. As regards Felling, the promoters failed to produce the consent of the local authority or to satisfy the Board of Trade that it should be dispensed with, and the Board refused to proceed with the application in respect of that district.

Kendal Electric Supply Order (the borough of Kendal).—Corporation.—Order granted.

Leek Electric Lighting Order (the urban district of Leek).—Urban District Council.—Order granted.

Littleborough Electric Lighting Order (the urban district of Littleborough).—Urban District Council.—Order granted.

Liversedge Electric Lighting Order (the urban district of Liversedge).—Urban District Council.—Order granted.

Llandilo Electric Lighting Order (the urban district of Llandilo).—Urban District Council.—Order granted.

Llanrwst Electric Lighting Order (the urban district of Llanrwst and portion of the rural district of Geirionydd).—Llanrwst Electricity Supply Company, Limited.—Order granted for the urban district of Llanrwst. The promoters were unable to obtain the consent of the local authority for the Geirionydd rural district, and withdrew the application in so far as it related to any part of that district.

The County of London.

Battersea Electric Lighting Order (portions of the parish of St. Mary, Battersea).—County of London and Brush Provincial Electric Lighting Company, Limited.—The local authority refused to consent to the application, but the Board of Trade, for the reasons stated in the special report made by them and presented to Parliament, decided to dispense with the consent of the local authority, and granted the order.

Lambeth (part of) Electric Supply Order (portion of the parish of Lambeth).—South London Electric Supply Corporation, Limited.—The promoters failed to produce the consent of the local authority or to satisfy the Board of Trade that it should be dispensed with, and the Board refused to grant the order.

Limehouse District Electric Lighting Order (the Limehouse district).—Board of Works.—Order granted.

Marylebone Electric Lighting Order (the parish of Mary

Digitized by Google

lebone).—Marylebone Electric Supply Company, Limited.—The local authority refused to consent to the application, and the Board of Trade held an enquiry in the matter. After consideration of the representations made to them, the Board of Trade, for the reasons stated in the special report made by them and presented to Parliament, decided to dispense with the consent of the local authority, and granted the order.

Mile End Old Town Electric Lighting Order (the hamlet of Mile End Old Town).—Vestry.—Order granted.

St. George-in-the-East Electric Lighting Order (the parish of St. George-in-the-East).—Vestry.—Order granted.

Long Eaton Electric Supply Order (the urban district of Long Eaton).—Urban District Council.—Order granted.

Lytham Urban District Council Electric Lighting Order (the urban district of Lytham).—Urban District Council.—Order granted.

Malton Electric Lighting Order (the urban district of Malton).—Northern Counties Electricity Supply Company.—Order granted.

Maryport Electric Lighting Order (the urban district of Marport).—Urban District Council.—Order granted.

Midland Electric Power Distribution and Lighting (Extension) Order (the borough of Smethwick, the urban districts of Oldbury, Perry Bar, and Stourbridge, the township of Upper Penn in the Seisdon rural district, and the parish of Bushbury, in the Cannock rural district).—Midland Electric Corporation for Power Distribution, Limited.—Order granted in respect of the township of Upper Penn in the Seisdon rural district and the parish of Bushbury in the Cannock rural district. Application refused as regards other districts.

Nantwich Electric Lighting Order (the urban district of Nantwich).—Urban District Council.—Order granted.

Neath, Briton Ferry, and Aberavon Electric Lighting Order (the municipal boroughs of Neath and Aberavon, and the urban district of Briton Ferry).—Electrical Power Distribution Company, Limited).—The promoters failed to produce the consents of the local authorities or to satisfy the Board of Trade that they should be dispensed with, and the Board refused to grant the order.

Newark Electric Lighting Order (the borough of Newark).—Corporation.—Order granted.

Newhaven Electric Lighting Order (the urban district of Newhaven). — Rev. H. G. Bonnewell and others. — Order granted.

Nuneaton and Chilvers Coton Electric Lighting Order (the urban district of Nuneaton and Chilvers Coton).—Urban District Council.—Order granted.

Ogmore Valley Electric Lighting Order (portion of the urban district of Ogmore and Garw.)—Ogmore Valley Electric Light and Power Supply Company, Limited.—Order granted.

Ormesby Electric Lighting Order (the urban district of Ormesby).—Urban District Council.—Order granted.

Ormskirk Electric Lighting Order (the urban district of Ormskirk).—Urban District Council.—Order granted.

Penrith Electric Lighting Order (the urban district of Penrith).—Urban District Council.—Order granted.

Penzance Electric Lighting Order (the borough of Penzance).—Corporation.—Order granted.

Prestwich Electric Lighting Order (the urban district of Prestwich).—Urban District Council.—Order granted.

Pwllheli Electric Supply Order (the borough of Pwllheli).—Corporation.—Order granted.

Ramsgate (Corporation) Electric Lighting Order (the borough of Ramsgate).—Corporation.— Order granted.

Ramsgate Electric Lighting Order (the borough of Ramsgate). Isle of Thanet Electric Tramways and Lighting Company, Limited. An application was also received from the local authority, to which preference was given by the Board of Trade in accordance with their usual practice, and the company's application was not proceeded with.

Redcar Electric Lighting Order (the urban district of Redcar).—Urban District Council.—Order granted.

Redruth Electric Lighting Order (the urban district of Redruth).—Urban Electric Supply Company, Limited.—Order granted.

Romford Electric Lighting Order (the urban district of Romford and the parish of Romford Rural in the rural district of Romford).—Urban District Council.—Order granted.

Royal Leamington Spa Electric Lighting Order (the borough of Royal Leamington Spa).—Midland Electric Light and Power Company, Limited.—The local authority refused to consent to the application, but the Board of Trade, for the reasons stated in the special report made by them and presented to Parliament, decided to dispense with the consent of the local authority, and granted the order, subject, however, to a provision that the order shall not come into force unless the local authority make default in putting into operation the order obtained by them in 1899 as provided by Section 3 of that order.

St. Helens (Isle of Wight) Electric Lighting Order (the urban district of St. Helens, Isle of Wight).—Edmund Ironside Bax, Esq.—Order granted.

Sandgate Electric Supply Order (the urban district of Sandgate).—Urban District Council.—Order granted.

Seaford Electric Lighting Order (the urban district of Seaford).—Rev. H. G. Bonnewell and others.—Order granted.

Seaham Harbour Electric Lighting Order (the urban district of Seaham Harbour).—County of Durham Electrical Power Distribution Company, Limited.—The promoters failed to produce the consent of the local authority or to satisfy the Board of Trade that it should be dispensed with, and the Board refused to grant the order.

Sevenoaks Electric Lighting Order (the urban district of Sevenoaks).—Electrical Power Distribution Company, Limited. Order granted.

Sheerness Electric Lighting Order (the urban district of Sheerness).—Electrical Power Distribution Company, Limited. Order granted.

Sleaford Electric Lighting Order (the urban district of Sleaford).—Urban District Council.—Order granted.

South Blyth Electric Lighting Order (the urban district of South Blyth).—Northern Counties Electricity Supply Company. Order granted.

Southwold Electric Lighting Order (the borough of Southwold).—Corporation.—The Board of Trade declined to grant the order, as the promoters failed to satisfy them that they were in a position financially to give effect to the order if granted.

Sowerby Bridge Electric Lighting Order (the urban district of Sowerby Bridge).—Urban District Council.—Order granted.

Spennymoor Electric Lighting Order (the urban district of Spennymoor).—Northern Counties Electricity Supply Company.—Order granted.

Staines, Egham, and Chertsey Electric Lighting Order (the urban districts of Staines and Chertsey and the rural district of Egham).—Electrical Power Distribution Company, Limited.—The local authorities for Staines and Chertsey consented to the application, but the local authority for Egham refused their consent. After consideration of the circumstances the Board of Trade, for the reasons stated in the special report made by them and presented to Parliament, decided to dispense with the consent of the Egham local authority, and granted the order for the three districts.

Stamford Electric Lighting Order (the borough of Stamford). Urban Electric Supply Company, Limited.—Order granted.

Sudbury Electric Lighting Order (the borough of Sudbury).—Corporation.—Order granted.

Teddington and Twickenham Electric Lighting Order (the urban districts of Teddington and Twickenham).—Richmond (Surrey) Electric Light and Power Company, Limited.—The promoters decided not to proceed with the application.

Thirsk Electric Lighting Order (the parishes of Thirsk and Sowerby in the Thirsk rural district).—Northern Counties Electricity Supply Company.—Order granted.

Totnes Electric Lighting Order (the borough of Totnes).—Totnes Electricity Supply Company, Limited.—Order granted.

Tunstall Electric Lighting Order (the urban district of Tunstall and the parishes of Goldenhill and Chell in the rural district of Wolstanton).—Urban District Council.—Order granted.

Twickenham and Teddington Electric Lighting Order (the urban districts of Twickenham and Teddington).—Twickenham and Teddington Electric Supply Company, Limited.—Order granted for the urban district of Twickenham. The promoters failed to produce the consent of the local authority for Teddington, or to satisfy the Board of Trade that it should be dispensed with, and the Board decided to exclude that district from the order.

Uxbridge and District Electricity Supply Order (the urban district of Uxbridge, the rural district of Uxbridge (except the parish of Northolt), and the parishes of Iver, Denham, and Gerrard's Cross in the Eton rural district).—Uxbridge and District Development Syndicate, Limited.—Order granted in respect of the Uxbridge urban district, the parishes of Hillingdon East, Ickenham, Cowley, and Hayes, in the Uxbridge rural district, and the parish of Denham, in the Eton rural district. Application refused in respect of the remainder of the area applied for.

Wallington Electric Lighting Order (the parish of Wallington, in the rural district of Croydon).—County of Surrey Electrical Power Distribution Company, Limited.—Order granted.

Wellingborough Electric Lighting Order (the urban district of Wellingborough).—Electrical Power Distribution Company, Limited.—Order granted.

Weybridge Electric Lighting Order (the urban district of Weybridge).—Urban Electric Supply Company, Limited.—Order granted.

Whitefield Electric Supply Order (the urban district of Whitefield).—Urban District Council.—Order granted.

Witney Electric Lighting Order (the urban district of Witney).—Witney Electric Supply Company, Limited.—Order granted.

Woking Electric Supply Company Electric Lighting Order (the parishes of Woking and Horsell, and portions of the

Digitized by Google

parish of Chertsey).—Woking Electric Supply Company, Limited.—Order granted.

Wormit and Woodhaven Electric Lighting Order (portions of the districts of Wormit and Woodhaven, in the parish of Forgan).—Tayside Electric and Gaslight Company, Limited.—Order granted.

Of these applications (108 in number), 59 were made by local authorities and 49 by companies or persons. Of these latter only 39 were passed by the Board of Trade, and one of these—*i e*, the Marylebone electric lighting order—was thrown out by the House of Commons. All the applications by local authorities were successful. The Board of Trade also report that during the year ending in June the following electric lighting orders have been transferred from the first mentioned to the last-mentioned:

Audenshaw Electric Lighting Order, 1899.—Corporation of Manchester.

Barnet Local Board Electric Lighting Order, 1893.—North Metropolitan Electrical Power Distribution Company, Limited.

Carshalton Electric Lighting Order, 1898.—County of Surrey Electrical Power Distribution Company, Limited.

Droylsden Electric Lighting Order, 1897.—Corporation of Manchester.

Gateshead Electric Lighting Order, 1899.—County of Durham Electrical Power Distribution Company, Limited.

Godalming Electric Lighting Order, 1896.—Urban Electric Supply Company, Limited.

Heaton Norris Electric Lighting Order, 1899.—Corporation of Manchester.

Hertford Electric Lighting Order, 1891.—North Metropolitan Electrical Power Distribution Company, Limited.

Lewes Electric Lighting Order, 1898.—County of Sussex Electrical Power Distribution Company, Limited.

Margate Electric Lighting Order, 1896.—Isle of Thanet Electric Tramways and Lighting Company, Limited.

Sutton Electric Lighting Order, 1892.—County of Surrey Electrical Power Distribution Company, Limited.

Weston-super-Mare Electric Lighting Order, 1891.—Weston-super-Mare and District Electric Supply Company, Limited.

Whiston Rural District Electric Lighting Order, 1898.—British Insulated Wire Company, Limited.

It is curious to note that electric lighting licenses have been granted during the year in question. Thus a license was granted on July 28 to the Corporation of Birkenhead and to the Ingleton Electric Light and Power Company on July 31, 1899. The report gives a full list of all the provisional orders which have ever been granted, with remarks as to those which have been revoked, and also some useful information as to the working of the new Electric Light Clauses Act.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Varna.—The Municipality invite tenders for the lighting of the town by electricity for 40 years by Oct. 15 (concession).

Beetle.—The Corporation invite tenders for a steam dynamo. Tenders by Oct. 13. Details in our advertisement columns.

Bermondsey.—The Vestry invite tenders for the erection of steam dynamos, etc. Tenders by Oct. 15. Details in our advertisement columns.

Paris.—The Postal and Telegraph Department, rue de Grenelle, No. 103, invite tenders for a number of telephone apparatus. Tenders by Oct. 16.

Swansea.—The Corporation invite tenders for the supply and erection of arc lamps, etc. Tenders by Oct. 10. Details in our advertisement columns.

Sunderland.—The Corporation invite tenders for 24 car bodies and electrical equipment. Tenders by Oct. 15. Details in our advertisement columns.

Maidstone.—The Corporation invite tenders for a surface condenser and feed pumps. Tenders by Oct. 16. Details in our advertisement columns.

Santiago.—Offers are invited for the laying down and working of a telephone system in Santiago de Compostela, in the province of Coruna, Spain. Tenders by Oct. 19.

Palma.—The Municipality of this town, in the province of Baleares, Spain, invite tenders for the installation and maintenance of 60 arc lamps. Tenders by Oct. 30.

Glasgow.—The Corporation invite tenders for cables for connecting up plant and transformer connecting bars. Tenders by Oct. 5. Details in our advertisement columns.

Wolverhampton.—Tenders are about to be advertised for for the material required in the making of the tramway section which runs from the Bilston-road terminus to Newbridge.

Cortegana.—Offers are invited for the installation of electric lighting and the working of same for five years in this town, in the province of Huelva, Spain. Tenders by Oct. 19.

Azuaga.—Offers are requested by the Municipality of this town, in the province of Badajoz, Spain, for the installation and working of the electric light for 20 years. Tenders by Oct. 11.

Callosa de Ensarria.—Offers are requested by the Municipality of this town, in the province of Alicante, Spain, for the installation and working of the electric light for 15 years. Tenders by Oct. 12.

Fuenteovejuna.—Offers are requested by the Municipality of this town, in the province of Cordoba, Spain, for the installation and working of the electric light for 20 years. Tenders by Oct. 9.

Manchester.—The Directors of the Lancashire and Yorkshire Railway Company invite tenders for the supply of various stores. Tenders by 10 a.m. on Oct. 8. Particulars in our advertisement columns.

Ilford.—The Urban District Council invite tenders for meters (direct-current) and cut-outs. Specification may be obtained from Mr. J. W. Benton, clerk, Council Offices, Cranbrook-road, Ilford. Tenders by Oct. 8.

Whitechapel.—The Electrical Committee invite tenders for the supply of a hand-driven overhead travelling crane for their new electricity supply station. Tenders by Oct. 23. Details in our advertisement columns.

Whitehaven.—The Water and Lighting Committee of the Corporation invite tenders for the supply and erection of a switchboard at their electric lighting station. Tenders by Oct. 13. Details in our advertisement columns.

Aberdeen.—The Tramways Committee invite tenders for the manufacture and supply of 25 electrical tramcars, and equipments for six horse cars, about to be converted. Tenders by Oct. 17. Details in our advertisement columns.

Grimsby.—The Corporation invite tenders for the wiring of the free library for electric lighting. Specifications and forms of tender can be obtained from Mr. W. A. Vignoles, borough electrical engineer, Grimsby. Tenders by Oct. 6.

Cardiff.—Tenders are invited for slow-speed vertical engines, slow-speed generators, boilers, and economisers. Specifications, etc., may be obtained from Mr. A. Ellis, M.I.E.E, Old Post Office-buildings, Cardiff. Tenders by Oct. 23.

Middleton (Lancs.).—The Corporation invite tenders for buildings required for electricity station. Specifications, etc., may be obtained at the offices of Messrs. Lacey, Clirehugh, and Sillar, 78, King-street, Manchester. Tenders by Oct. 11.

Nottingham.—The City Council invite tenders for 1,500 tons of steel girder tramrails and 76 tons of fishplates. Specifications, etc., may be obtained from Mr. Arthur Brown, M.I.C.E., city engineer, Guildhall, Nottingham. Tenders by Oct. 8.

Bradford.—The Corporation invite tenders for the construction and delivery of an engine and dynamo, also switchboard apparatus, etc., for their destructor works Southfield-lane, Bradford. Tenders by Oct. 9. Particulars in our advertisement columns.

Brighton.—The Town Council invite tenders for rewiring the abattoir premises, Hollingdean-road, for electricity installation. Specifications may be obtained from the borough engineer and surveyor, Mr. Francis J. C. May, M.I.C.E., Town Hall, Brighton. Tenders by Oct. 11.

Ayr.—The Council invite tenders for the supply and delivery of steel tramway rails and fishplates for the work required in connection with the proposed tramways. Specification, etc., may be obtained from Mr. J. Young, C.E., town surveyor, Town Buildings, Ayr. Tenders by Oct. 12.

Dartford.—The Urban District Council invite tenders for the erection of an electric light station at Dartford, in accordance with drawings and specifications prepared by their architects. Specifications may be seen at the office of Messrs. Hesketh and Stokes, 110, Cheapside, E.C. Tenders by Oct. 20.

Dundee.—The Gas Commissioners invite tenders for the supply and erection of three steel water-tanks at the electric lighting station, Dudhope-crescent-road, Dundee. Specification, etc., may be obtained from Mr. Walter H. Tittensor, city electrical engineer, Dudhope-crescent-road, Dundee. Tenders by Oct. 12.

Glasgow.—The Corporation invite tenders for the supply of 1,000, 2,000, or 3,000 tons steel straight track rails; 100 200, or 300 tons steel curved rails; 50, 100, or 150 tons steel fishplates. Specifications, etc., can be obtained from Mr. John Young, general manager, 88, Renfield-street, Glasgow. Tenders by Oct. 23.

Sheffield.—The Corporation invite tenders for specification No. 3 (a) two two-phase steam alternators and exciters, 600 kw. each; (b) alteration of present single-phase plant to two-phase. Specifications can be obtained from Mr. S. E. Fedden, chief engineer and manager, Commercial-street, Sheffield. Tenders by Oct. 6.

Brussels.—The Government Railways require a number of insulators, 150 tons of galvanised iron wire, and a large amount of various telephone and telegraph material. Particulars (special specification No. 59) may be obtained from that authority. The adjudication takes place at the Brussels Exchange on Oct. 10 at 11 a.m.

Whitechapel.—The Board of Works invite tenders for erection of a chimney shaft and the construction of economiser chambers, flues, and cableways at the new electrical supply station yard, Osborne-street, Whitechapel, E. Drawings may be seen at the office of Mr. M. W. Jameson, engineer and surveyor to the Board. Tenders by Oct. 16.

Digitized by Google

London (City).—The Streets Committee of the Corporation invite tenders for the hiring of a mechanically-driven dust-cart for collecting and removing the dust, trade refuse, and street sweepings from the City to the Corporation's depôt at Lett's Wharf, Commercial-road, Lambeth, S.E. Tenders by Nov. 10. Details in our advertisement columns.

Medomsley (Durham).—The Parish Council invite tenders for the supply and erection of electric lamps, posts, cables, etc., necessary for the lighting of the road leading from Black Hall Mill to Medomsley Village, via Westwood Colliery. Particulars may be obtained from Mr. M. T. Milburn, Medomsley, R.S.O., clerk to the Council, and the ground may be viewed on making an appointment by letter.

India.—The Secretary of State for India in Council is prepared to receive tenders for the supply of a complete electrical installation for supplying power to a factory from a waterfall about three miles distant from factory. The generator will be required to develop about 500 kw., and the installation is to include complete plant of generators, line, transformers, cables, motors, etc. Conditions, etc., may be obtained from the Director, General Stores, India Office, Whitehall, S.W., and tenders are to be delivered at that office by 2 p.m. on Oct. 16.

Norway.—The Secretary for Foreign Affairs has received a dispatch from her Majesty's Consul-General at Christiania stating that tenders are invited by the Stavanger Corporation for the establishment of electrical communication or transmission of power from the Altesrig Waterfalls to Stavanger, a distance of about 39 kilometres, in accordance with the plans of a civil engineer named Schoien. Tenders must be received by Jan. 2, 1901. Further information may be obtained on application to Mr. E. Berentsen, British Vice-Consul, Stavanger.

RESULTS OF TENDERS.

Ayr.—The Corporation have placed the contract for two 200-kw. P.P.P. traction and lighting generators, coupled to Belliss engines, with Messrs. D. Bruce Peebles and Co.

Barrow-in Furness.—The Corporation have placed the contract for a year's supply of motors for hiring-out purposes from 1 h.p. to 10 h.p. with Messrs. D. Bruce Peebles and Co.

Cotswold Sanatorium.—The Hart Accumulator Company, Limited, Marshgate-lane, Stratford, have secured the order for the supply of storage battery required for the electric lighting of this institution.

Leeds.—The Tramways Committee have accepted the tenders of W. Irwin and Co., Leeds, general trades, £7,595; Clayton, Son, and Co., Leeds, ironwork, £2,973. 16s., with reference to the erection of a new boiler-house at the generating station, Crown Point, Leeds.

Southampton.—The Guardians have accepted the tender of Messrs. Lankester and Son, High-street, Southampton, at £3,499. 10s., for the erection and completion of electrical plant and installation for the lighting of the new workhouse infirmary, Shirley Warren.

Wigan.—The Tramways Committee have accepted the following tenders for the Wigan-lane section of the tramways: Esther and Co., poles and section pillars; Blackwell and Co., bonds and castings; Bergtheil and Young, overhead material; Naylor Bros., brackets; Macartney, McElroy, and Co., trolley wire.

Worthing.—The Electric Lighting Committee have accepted the following tenders: Scott and Mountain, dynamos, £2,850; Danks and Co., boilers, etc., £1,130; Callender's Cable and Construction Company, manhole covers, £501. 3s.; Mackenzie Bros., arc lamp-posts, £1,353. 5s.; Albion Clay Company, stoneware casings, £2,102. 3s. 6d.; Callender's Cable and Construction Company, cable work, £5,967. 15s. 3d.; Eclipse Brass and Copper Company, York, storage batteries, £984. 4s.; Laurence, Scott, and Co., boosters, etc., £710; Lowcock, Limited, economiser, £372. 10s.; Carrick and Ritchie, travelling crane, £165.

Croydon.—The tender of Askham Bros. and Wilson, Limited, for the supply of points and crossings, has been accepted. The British Electric Traction Company have agreed to the Corporation accepting the following contracts—viz.: (Contract No. 2) British Thomson-Houston Company, car bodies; (3) British Thomson-Houston Company, motorcar equipment; (4) British Thomson-Houston Company, feeders; (5) British Thomson-Houston Company, overhead construction; (6) British Thomson-Houston Company, excavating and ground wires; Thornton Heath depôt car-shed—J. Smith and Son, builders' work; G. Sands and Son, smith and founders' work; Brighton road car-shed—E. J. Saunders, builders' work; G. Sands and Son, smith and ironfounders' work. The prices, etc., were discussed by the Council at a private sitting last week.

BUSINESS NOTES.

LIGHTING AND GENERAL.

Eastbourne.—The Town Council have decided to establish a municipal telephone exchange.

Guildford.—The Council are still considering the question of the provisional order for electric lighting.

Luton.—Mr. Snell has forwarded designs of arc lamp columns, and the positions of the 10 columns have been fixed.

Tynemouth.—It is reported that the system of electricity for the lighting of the borough is fast nearing completion.

Russia.—An experimental telephone line is shortly to be laid between St. Petersburg and Moscow, a distance of about 650 miles.

Pontypridd.—The Urban District Council are applying for an electric lighting order. A refuse destructor plant is to be included in the scheme.

Edinburgh.—The Town Council have placed the balance of £3,674. 9s. 4d. from the electric lighting account to the credit of the reserve fund.

Removal.—The Lilleshall Company, Limited, have removed from Lime-street to 71, Finsbury-pavement (Electric Railway Station Buildings).

Poplar.—The ceremony of opening the electricity works of the District Board of Works at Glaucus-street, Bromley, E., has been fixed at 4 for 5.30 on Monday, Oct. 8.

Hampstead.—The Lighting Committee are considering the necessity of extending the electric arc lamps from Fortune green to the corner of Platt's-lane, Finchley-road (south side).

Carmarthen.—The Electric Light Committee of the Town Council have decided to engage Messrs. Medhurst and Lloyd, of London, to report upon a system of public electric lighting.

Lymington.—Mr. H. Preston is proceeding rapidly with the erection of the necessary premises at Bath-road which are to form the works of the Lymington Electric Light and Power Company.

Norton (Malton).—The District Council have consented to an application by the Northern Counties Electric Supply Association for a provisional order for the supply of electricity in the district under certain conditions.

Aberdeen.—A plan of the proposed new electricity works at Dee Village, showing Millburn street to be widened from 20ft. to 45ft., has been adopted, also the erection of a chimney stalk 200ft. high, at an estimated cost of £2,900.

Colne.—The Town Council have received the sanction of the Board of Trade to the scheme to be adopted by the Corporation for the supply of electrical energy as per their electric light order, the work to be undertaken forthwith.

African Telegraph.—The African Trans-Continental telegraph line is completed to Kituta on the south end of Lake Tanganyika, and is expected to be carried by the end of July across the Anglo-German frontier to Kassanga, the German station north of Kituta.

Anglo-American Telegraph Co.—The directors, after placing £6,000 to the credit of the renewal fund, announce an interim dividend for the quarter ending 30th ult. of 15s. per cent. on the ordinary stock and £1. 10s. per cent. on the preferred stock, payable Nov. 1.

Warrington.—The promoters of the Manchester and Liverpool Electric Express Railway having intimated their intention to reintroduce a Bill in the next session of Parliament, the Town Council on Wednesday resolved to accept the agreed clauses for insertion in the Bill.

Wigan.—The electrical engineer's report on the extension of the area of supply of electric current has been adopted, and application is to be made to the Local Government Board to borrow the amount required in such instalments as may be necessary for the extension from time to time.

Sussmann Electric Miners' Lamp Co.—This Company has been registered with a capital of £30,000 in £1 shares, the object being to acquire the business of the Sussmann Electric Miners' Lamp Company, Limited, to adopt an agreement with the said old company and its liquidator, etc.

Nelson.—Mr. M. R. North has held an enquiry into the Corporation's application for sanction to borrow £2,500 for electric lighting purposes for the borough. The Town Clerk explained that the present application was to provide an extension of the present storage battery by the addition of 72 cells.

Eastern Telegraph Co.—The directors announce payment on 15th inst. of a dividend at the rate of 3½ per cent. per annum on the preference stock of the Company for the quarter ending 30th ult., and the usual interim dividend of 1¼ per cent. on the ordinary stock in respect of profits for the quarter ended June 30.

Friern Barnet.—At the last meeting of the Urban District Council the Clerk reported that the work in connection with the initial stages of the electric lighting scheme was being proceeded with, and that he was at present in communication with the Board of Trade getting information on questions affecting the local scheme.

York.—At the last monthly meeting of the City Council, it was stated that the Electric Lighting Committee had during the past six months made a trading profit on the lighting of upwards of £200. After the interest and sinking fund were paid about £100 would be left. This is very satisfactory, and it is anticipated that in the next six months a very good profit will be shown.

Barnsley.—The borough electrical engineer is preparing specifications for an additional engine and dynamo for the electricity works. A special meeting of the Electricity Committee was held on Tuesday for the purpose of inspecting the public lamps in the borough, and of deciding what existing lamps shall be moved to other positions, and where additional lamps shall be placed.

Worcester.—In consequence of the continued increase in the price of coal the Electricity Committee propose to increase the prices of the current to consumers, as follows: to private customers, 6½d. and 3d. per unit; for waterworks motors, 1¾d. per

Digitized by Google

unit; for the public arc lamps, an additional two guineas for each all-night lamp, and one guinea for a half-night lamp; and for the public incandescent lamps, 5s. each per annum.

Hereford.—It was reported at Tuesday's meeting of the Town Council that the cost of the town's electric light works was £20,470. 16s. 2d. The demand for the current has exceeded the expectations. The present installation represents the equivalent of 6 822 8-c.p. lights, and altogether there are over 7,500 lights. Applications have been made for current which it is estimated will represent a supply of considerably more than 500 additional lights.

Macclesfield.—On Thursday week a special meeting of the General Purposes Committee of the Corporation—which consists of the whole of the members of the Council—was held for the purpose of considering the proposal of the Electrical Power Distribution Company to apply for a provisional order enabling them to establish an electrical installation in Macclesfield. An amendment that a provisional order be applied for on behalf of the Council was carried.

Sutton Coldfield. — The Highways Committee reported at Wednesday's meeting of the Town Council that, with a view to facilitating the establishment of telephonic communication in Sutton Coldfield, they had granted to the National Telephone Company permission to erect five poles in Green-lane and 38 poles in Penn's-lane, and it was stated that telephonic communication would be established between the borough and the adjoining towns within the next six months.

Berkhampstead.—At a recent meeting of the District Council a letter was received from the Herts County Council, explaining the relation of district councils to the North Metropolitan Electric Supply Company, who had recently got a Bill passed through Parliament, and stating that the County Council would be willing to assist any district council that was desirous of obtaining powers for themselves. The Council decided to take the necessary steps to obtain themselves the position of distributors.

New Firms.—We are informed that Prof. Alex. B. W. Kennedy's business will henceforth be carried on under the style of Kennedy and Jenkin, the partner being Mr. Bernard M. Jenkin, and the address 17, Victoria-street, Westminster.—Mr. J. Wemyss Anderson, A.M.I.C.E., M.I.Mech.E., has arranged a partnership in connection with electrical work with Mr. Alfred Hay, B.Sc., M.I.E.E., and the business of consulting electrical engineers will be carried on at Pearl Assurance-buildings, Liverpool.

London Gazette.—A receiving order has been made out *re* T. W. Greaves and W. G. Randall (lately trading as T. W. Greaves and Co., at 230, East India Dock-road, and 6, Nelson-street, Greenwich), on debtors' petition. An adjudication order has also been made out *re* the above. A first and final dividend of 2s 8½d. per pound has been declared *re* B. Symons (trading as B. Symons and Co.), 2, North-street Quadrant, Brighton, Sussex, payable at the offices of Ward and Wilding from Oct. 5.

Carnoustie.—At the last meeting of the Burgh Commission the Clerk reported receipt of a letter from the Board of Trade anent the transference of an electric lighting order from a local authority to a contracting firm. The Department stated that unless any special reasons could be urged, they had decided not to insert such powers in the future. The Clerk also stated that the Electrical Supply Company had promised a reply within a few days to his communication as to whether they would withdraw their application for an order for Carnoustie.

Belfast —The Corporation have resolved that motor consumers be allowed to take not more than one 16-c.p. lamp off the motor circuit, this lamp to be only for use in connection with the motor, the current for same being charged at motor rate. Six prepayment meters will be installed as an experiment. The charge has been fixed at 5½ d. per unit for all current consumed; 4½d. of this sum will go to the credit of the Corporation, and the remainder—viz., ¾d.—to the credit of the National Free Wiring Company, as rent on the wiring and fittings in premises installed by them.

Appointments Vacant.—The West Bromwich Corporation invite applications for the appointment of borough electrical engineer.—The West Hartlepool Corporation are prepared to appoint two assistant engineers, at a commencing salary of £120 per annum, rising by yearly increments of £10 to £150.—The services of a mains superintendent are required by the Corporation of Southampton.—The borough of Blackburn have a vacancy for a shift engineer.—The Ashton under Lyne Corporation invite applications for the post of switchboard assistant at their electricity works. Full particulars of these vacancies appear in our advertisement columns.

Cardiff.—A report upon the recent accident was submitted by Mr. W. H. Illingworth, mains superintendent, at the last meeting of the Electric Lighting Committee containing some suggestions for the improvement of the low-tension system. After considerable discussion on the propriety of receiving the report it was eventually decided that it be referred to Mr. Appelbee, and that the latter be asked to report upon the suggestions contained therein to a meeting of the Electric Lighting Committee to be held to-morrow. It was stated at the last meeting, and there appears to be a good deal of truth in it, that a good many of these difficulties were due to the unwarrantable interference of the committee in matters of petty detail.

Stirling.—At a recent special meeting of the Police Commission, Town Council, and Local Authority it was explained, in connection with the electric lighting account, that the expenditure included £834 as instalment of principal of £25,000 loan, and £665 of interest, the station costs being: management, £265; wages, £435; coal, £500; and stores, £180—the total estimated outlay being £2 879. The income from consumers was calculated at £1,750, being 5,000 lamps at 7s. per lamp, with £510 from arc lamps, and £619 from assessments. There was £2,479 of the £25,000 loan unexpended, but there were a few accounts still unpaid. The sum of the credit of the Council for new municipal buildings was £2,326.

Inefficient Telephone Service.—The National Telephone Company in the City of London Court, on Tuesday, sought to recover £50 from Messrs. Daniel de Pass and Co., Fenchurch-buildings, E.C., for the use of a private telephone wire from their City office to their branch establishment at Barking. Messrs. de Pass and Co. declined to pay because the wire had never been efficiently fixed. The plaintiffs, on the other hand, declared that the wire had been fixed as well as possible. For four miles the wires had to stretch alongside the sewer bank, and on several occasions whole lengths of wire had been cut off and taken away. The company did not guarantee that the telephones should work always. The jury gave judgment for the defendants.

Leeds.—The City Council on Wednesday agreed to apply to the Local Government Board for permission to borrow £510,500 for electric lighting purposes. This sum includes the sum of £177,573 already sanctioned by the Council, for which the Local Government Board enquiry had not yet been held. This proposed loan further includes £100,000 for general extensions, and £80,000 for extensions on the main line of road to Wortley, New Wortley, Armley, and Bramley, and on to Stanningley. It also covers a scheme of crossing the river again and extending up with the West Hunslet direction, through Globe-street, that would require at least £80,000. A sum of £140,000 is provided for development and extension and the provision of new buildings and of machinery on the site already occupied.

St. Albans.—The Guardians recently received the following report from Mr. Miskin: "As requested by the Electric Lighting Sub-Committee of the Board of Guardians, I give below a summary of the probable cost of installing the electric light at the workhouse. From information obtained of the master, there will be required about 85 16 c.p. lamps and 38 8 c.p. The cost would be approximately as follows: wiring generally to all points including fittings, £200; dynamo with necessary mountings, £75; switchboards, belting, steam connections, beds for dynamo and engine, £68; accumulators, complete with stands, fixing, and connecting, £285; 9 b.h.p. vertical steam engine, fixed £85; allow for contingencies, £50—total, £763. Owing to the fact that a man will have to be employed to attend to laundry and boiler, the extra wages involved by the lighting plant would be very small, as the same man could attend to both. I consider £50 would cover the annual expenditure involved, including coal, water, extra wages paid, and maintenance." No definite resolution has been passed.

Enfield.—At a recent meeting of the Electric Lighting Committee of the Urban District Council the Clerk stated that, in reply to certain queries put to the North Metropolitan Electric Power Distribution Company, Limited, Mr. Offor, representing the company, had submitted a draft agreement embodying the proposals of his company. Mr. Offor attended the meeting, and, after a discussion lasting nearly two hours, it was agreed that he should take back the agreement for the purpose of embodying such of the proposals made by the committee as were acceptable to his company, and return the amended draft. Mr. Trenchard said the clerk and he attended a conference of local authorities at the Tottenham School Board offices the previous night with reference to the proposed promotion of a Bill in Parliament to confer powers on district councils for supplying electric lighting powers. The proposals submitted from Enfield that the joint authority should distribute, as well as generate, the light was accepted, and a draft agreement was decided upon subject to the Council's opinion on one point.

West Bromwich.—The Electric Lighting Committee's report recommends that the charge for electricity for lighting purposes be fixed at the rate of 6d. per unit until an equivalent of 100 hours' maximum demand has been reached in each quarter, and thereafter during the same term at the rate of 2d. per unit; that the charge for electricity for power purposes be at the rate of 3d. per unit until an equivalent of 78 hours' use of the maximum demand has been reached in each quarter, and thereafter during the same term at the rate of 1d. per unit. They also recommend that the system known as the "free-wiring system" be adopted. They further recommend that application be made to the Local Government Board for sanction to borrow £10,000 for providing materials and labour for wiring houses, and also for the purchase and fixing of motors. A further demand for power purposes has been made upon them, and to meet this the engine house must be enlarged, and they have agreed to carry out the extension at once. They have decided to advertise for a borough electrical engineer at a commencing salary of £250 per annum.

Sunderland —Various tenders for dynamos and boilers have been referred to Mr. Snell to report upon. The Finance Committee have been authorised to borrow the requisite money for the erection of the new lighting station, purchase of plant, and making connections, and the cost of laying the mains to Roker. The Electric Light Committee have recommended the Council to give customers the option of being supplied on the maximum demand system or to take off a discount upon the number of units used, on a scale which had been in force before the maximum demand system was adopted. Under this scale customers using 200 units per quarter will receive 2½ per cent. discount; those consuming 600, 5 per cent.; 1,000 units, 7½ per cent; 1,500 units, 10 per cent.; 2,500 units, 15 per cent.; and 5,000 units, 20 per cent. In

Digitized by Google

regard to meter rents it was decided to recommend that they be reduced about an average of 3s. per meter per year. These changes will represent a difference of £70 per annum in regard to meter rents and £111 per annum in regard to the discount, but the committee hope to increase the number of their customers and the amount of light used.

Newcastle Electric Supply Co.—A circular has been issued to the shareholders calling attention to the extended powers of the company under an Act of Parliament, which had recently received the Royal assent and become law, and announcing an extraordinary general meeting for yesterday. Under the powers now possessed by the company, the area of supply of electricity in bulk and in detail has been greatly extended, the districts of Gosforth and Longbenton being included; and it is also pointed out that by arrangement with the Council of the urban district of Walker that district will be supplied, as will the Walker and Wallsend Union Gas Company, with the whole of the electric energy in bulk required by them. It is pointed out that the organisation of the company requires to be at once extended and strengthened; and the directors will ask the meeting to vary the articles of association so as to allow of an increase in the number of directors by the addition of several gentlemen, who will assist in the maturing and carrying out of the extended plans and operations necessary in the erection of a new large power station. The names of Sir Lindsay Wood, Bart., and Mr. H. B Noble are mentioned in this connection.

Glasgow.—At the last meeting of the City Council the Statute Labour Committee reported recommending that the application for permission to lay cables by the Corporation telephone department be granted. The master of works stated that the plan showed that the cables were intended to be laid in nearly every street within the district bounded by the River Clyde, Hope-street, George-street, High-street, and Salt-market. He saw no objection from the statute labour point of view, except that there would be an enormous interference with the public use of the streets for a considerable time to come. None of the streets to be opened up could be put into a satisfactory condition for more than 12 months from the time the first opening is made. The committee, having considered the matter, agreed to recommend that, so far as the streets in question were public streets, the permission of the Corporation (Police Department) be granted on the understanding that, with the view of minimising inconvenience to the public, the Telephone Department carry out, as required by the master of works, the work in streets that may be for other purposes opened up, and that the pavements of streets be, as far as possible, utilised instead of the roadway.

Stock Exchange. — The Stock Exchange Committee have appointed Oct. 11 as a special settling day for Eastern Extension, Australasia, and China Telegraph Company's further issue of 50,000 shares of £10 each (issued at £3 per share premium), £6 paid (of which £3 is capital and £3 is premium), Nos. 250,001 to 300,000. The committee have also ordered the undermentioned securities to be quoted in the official list: British Columbia Electric Railway Company's further issue of 1,600 5 per cent. non-cumulative preference shares of £10 each, fully paid, Nos. 37,001 to 38,600; Eastern Extension, Australasia, and China Telegraph Company's further issue of 50,000 shares of £10 each (issued at £3 per share premium), £6 paid (of which £3 is capital and £3 is premium). Nos. 250,001 to 300,060. Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to the United River Plate Telephone Company's further issue of 23,361 5 per cent. cumulative preference shares of £5 each; and Vickers, Sons, and Maxim's further issue of 500,000 ordinary shares of £1 each, fully paid, Nos. 1 500,001 to 2,000,000. The committee have further been asked to allow the National Telephone Company's £500,000 4 per cent. debenture stock to be quoted in the official list.

Rickmansworth.—At the last meeting of the Urban District Council, Mr. Offor, of the North Metropolitan Electric Power Distribution Company, attended the meeting to explain the company's proposal to light the district with electricity. He said the company had given formal notice of application for a provisional order. The special terms the company would make would not be included in the provisional order, but would be embodied in a supplemental agreement, because the Board of Trade objected to such contracts with local authorities. The company were prepared to undertake the supply of electricity for the street lamps at 3d. per unit. According to Sir William Preece six units were equivalent to 1,000 cubic feet of gas. On that basis 3d. a unit was equal to 1s. 6d. per 1,000ft. of gas. With regard to private supplies, the charge would be at the rate of 7d. per unit for the first hour and 3d. per unit for every hour afterwards. The ordinary consumer would, on the average, use the light for about three hours in the 24, and in such a case the average cost would be 4d. a unit. If anyone used electricity for only one hour a day, his custom would be a loss to the works. The company were also prepared to give the Council the option of purchasing the business as a going concern on the expiration of two years' notice, which could not, however, be given until the lapse of 12 years, or at a subsequent period of seven years, the value to be fixed by independent valuers. Of course, the company would make these arrangements in consideration of the Council consenting to the provisional order. The offer is to be considered by the Council.

Derby.—During the year ended March 31, 1900, a net profit of £113 has been made by the electric lighting undertaking. The increase in the price of coal is estimated to have reduced the profit by £700. The following estimate of expenditure on capital account during the next two years has been submitted by the electrical engineer—viz.: one new 1,000-h.p. engine and alternator with foundations, £8,650; one new 600-h.p. boiler, with superheater and economiser and brickwork, £2,000; one ejector condenser, £650; new chimney, £1,500; motors, £2,000; transformer, £750; meters, £750; extensions to switchboard, £450; piping to connect engine and boilers, £400; extension of mains, £7,500; sundries, £139; amount overspent, £7,190; retentions on existing contracts, £3,021—total, £35,000. With reference to the two last items in the above estimate—viz, £7,190 and £3,021—the committee beg to report that the sum of £850 had been expended on a stock of motors for hire, and £1,000 on a stock of cable. The greater portion of the amount overspent has been used on mains extensions rendered necessary by the rapid increase of demand for electricity in excess of the estimate made when the Council on Jan. 4, 1899, granted the sum of £25,000. The following figures show how rapidly the demand for current has increased during the past few years: 1895, lamps connected 13,554; 1896 18,000 (increase, 4,446); 1897, 20.783 (2,783); 1898, 28,043 (7,260); 1899, 35 909 (7,866); 1900 (to September), 44,959 (9,050). The Council propose to apply for sanction to borrow £35,000. Orders have been given for steam jets to be placed on two boilers at the electric lighting works to make a forced draught. Extensions of the mains have been ordered to the new Methodist Chapel, Dairy House-road, at a cost of £140, and to Abell's Foundry, Brook-street, at a cost of £100. The following is the new scale of charges for electricity, as an alternative mode of charging—viz: for all quantities up to 500 units per quarter, 5½d. per unit; for all quantities over 500 and not exceeding 1,000 units per quarter, 5d. per unit; for all quantities over 1,000 and not exceeding 2 000 units per quarter, 4½d. per unit; for all quantities over 2,000 and not exceeding 3,000 units per quarter, 4½d. per unit; for all quantities over 3,000 and not exceeding 4,000 units per quarter, 4½d. per unit; for all quantities over 4,000 units per quarter, 4d. per unit.

Wrexham.—The engineer's monthly report on the electric lighting work submitted to the Council last week stated: "There are still some details before the buildings are finally completed, but they are ready to receive engines, dynamos, and condenser. All the boilers have been delivered, and foundations completed ready to receive them. The men are now at work getting them into position, and there is nothing now to delay their completion. The water-tube boilers will probably be ready for steaming by the middle of October, but the Lancashire boiler will, of course, not be steamed until the destructor is complete. Two sets of machinery will be delivered at the depôt towards the end of this month, and the condenser is promised at the same time. We are urging the manufacturers of the steam and exhaust piping to push forward the delivery of same, and understand from them that there will be no delay. The makers of the switchboard assure us that they will be in a position to complete by the time this is required. A certain amount of progress has been made with the mains, lamps, etc, but we cannot regard it yet as satisfactory. The contractors have at length, however, got a large amount of material to proceed with, and we think that at the end of this month a large proportion of the cable should be laid. It will be as well to finally decide positions of arc lamps so that the contractors may have no excuse for further delay on that ground. The accumulators will be to hand when required. As mentioned in our last report, there has been great delay on the part of the rolling mills in manufacturing the rails. We understand that these have now been received and the contractors have promised to dispatch. The excavations for the foundations of the destructor have been got out, and there should now be nothing to delay rapid progress with this work." Mr. Trentham further stated that 31 arc lamps had been decided upon to date, and, as it was more convenient to switch nine lamps on and off by one switch, it was suggested that five extra arc lamps be obtained. The estimate of the extra cost, including additional length of cable, was £180, and the length of cable required in Egerton-street would be 180 yards, which, at 8s. 8d. per yard (the schedule price for a ·125 cable), would amount to £78, plus £10 for connecting-box in Regent-street. These works are to be carried out. The estimate of the cost of wiring the depôt premises for electric lighting was £85, and tenders are to be invited for the work. Messrs. Meldrum reported that repeated alterations had been made since their tender was accepted, necessitating new drawings, and generally delaying the work; and they mentioned that so late as the previous week an alteration was made in the position of the boiler. This will necessitate about a month's delay.

Royal Photographic Society.—The forty-fifth annual exhibition of the Royal Photographic Society opened on Oct. 1, and has been removed from its old quarters at the Society of Painters in Water Colours to the New Gallery in Regent-street. The exhibition, which will remain open until Nov. 3, was inaugurated last Saturday by a conversazione, at which Mr. Dallmeyer (the president) and Mrs. Dallmeyer received a very large number of ladies and gentlemen, who greatly enjoyed the many very fine specimens of the photographic art which have been collected together, and which cover the walls of four large rooms as well as those of the upper gallery. The absence of the crush hitherto unavoidable in the one room at Pall-mall East was not the least welcome feature of the evening. The exhibits, remarkable as most of them are both for composition and for technical execution, lie somewhat without the scope of this journal, and the various processes of photography in colours, of which very advanced specimens are shown, have already been described in our columns. The newest of this kind consist in transparencies on glass in colours, produced by the McDonough-Joly process, which is an improved and practical working out of an early method suggested

Digitized by Google

and demonstrated by Louis Ducos du Hauron. It is based, like most of the modern processes of colour photography, on the researches of Clerk-Maxwell and on the Young-Helmholtz theory of the nature and properties of light. It proceeds on lines of analysis and synthesis, breaking up the effect of light upon the photographic plate into three separate colour-sensation effects, the impressions of which are produced simultaneously by one exposure upon a single photographic plate, through the intervention of a screen ruled with the three fundamental colours—red, green, and violet, in very fine parallel lines. By viewing the resulting print or transparency through a second similar screen, properly adjusted, the three-colour effects are again combined, and produce a coloured representation of the original subject. The process can also be applied to the production of photo-mechanical prints in colours on paper, suitable for book illustration or other purposes. The best specimen shown is a stereoscopic photograph of a basket of fruit, by the Sanger Shepherd process of natural colour photography, negative and print by E. Sanger Shepherd and R. Lincoln Cocke. The present exhibition does not present anything new with regard to scientific instruments, no new inventions having been made during the last 12 months which come within its range. Dallmeyers exhibit a new telephotocamera with which some very remarkable results have been obtained. The Eastman Company's "Panoram" camera is also exhibited for the first time. The London Stereoscopic and Photographic Company, Limited, show some wonderfully clear photographs of electric machinery (15 by 12 direct pictures). Among the scientific, technical, and photo-mechanical prints exhibited upstairs we noticed several illustrating the radio-active properties of the metals, radium and polonium, and the action of uranium salts on photographic plates, by Dr. W. J. Russell, F.R.S.; some magnetograms, both by the bromide and the old wax-paper process, by the Rev. Walter Sidgreaves; a number of very interesting photomicrographs of diatoms, by E. M. Nelson; and of curious insects, by T. E. Freshwater; and three platinum prints of brain cells and of ganglia taken by the Zettnow filter at an exposure of 10 minutes, and by the Zettnow-Tavel filter at an exposure of from 12 to 17 hours, by Doctor G. Mann. There is also a curious series of pictures of snow crystals by Dr. R. Neuhauss, and a large number of enlarged astronomical photographs from the Royal Observatory, Greenwich.

TRACTION.

Strike.—A strike of tramway employés has begun at Marseilles.

British Electric Traction Company. — Warrants for the debenture interest have been posted.

Erdington.—A proposal in favour of the construction of tramways will come before the Council next month.

London United Tramways.—We refer elsewhere to the still postponed opening of these lines and its cause.

Newcastle.—It is not expected that any of the new lines of electric tramways will be ready for opening this year.

Nottingham.—The first section of the new electric tramways will be ready for opening in the first week of November.

Darlington.—The Light Railway Commissioners have provisionally approved the order for the scheme originally propounded for the Darlington tramways.

Little Lever.—Deputations from the Farnworth and Radcliffe Urban District Councils are to meet the Little Lever Committee on the matter of the proposed tramways.

Manchester.—We learn that the first section of the electric tramways will be ready in about four months, and the whole system will then be taken over gradually as fast as the new lines can be constructed.

Paisley.—Mr. W. M. Murphy, Dublin, is taking steps to promote another Bill for the forming of a new tramway scheme for the town and district. The new scheme is to be called the Paisley district tramways.

Paris.—The frequent collisions of tramcars are ascribed in the local Press to the inexperience of the drivers, and to the false economy of the companies, who employ only one engineer when two are absolutely necessary.

King's Norton.—The City of Birmingham Tramway Company have agreed to carry their existing line from the terminus at Bournbrook to Chapel-lane, Selly Oak, and to contribute £1,500 towards the lowering of the canal bridge.

Nelson.—The Board of Trade have authorised the service of notice by the Corporation on the Burnley Tramways Company, under the enabling powers of the Tramways Act, 1870 requiring the company to sell to the Corporation so much of their tramway undertaking as is within the borough.

Brisbane Tramways Co.—On and after April 1, 1900, the debentures forming an issue of £250,000 5 per cent. debentures of £100 each, Nos. 1 to 2 500, will be paid off in accordance with the sixth condition endorsed thereon at the National Bank on delivery of the debentures and all unmatured coupons.

Aberdeen.—The Tramway Sub-Committee have approved of the plans showing the connection of the proposed new electric tramway line to the Links to the line at the junction of George-street and Union-street. Part is to be a single line, as an agreement with the proprietor of certain property appears to be difficult to arrive at.

East Ham.—The probable date of the opening to traffic of the first section of the District Council's tramways, consisting of 5¾ miles of single track, is April next. The permanent way is complete, and the erection of the overhead trolley line will be finished in about a month from now, while the generating station and car depôt is also well advanced.

Lifeguards.—We learn that the Dudley, Stourbridge, and District Electric Traction Company have recently fitted one of their new electric tramcars with Messrs. Wilson and Bennett's lifeguard, which was exhibited at the recent tramway exhibition, when it was awarded the first prize. The appliance is manufactured by Messrs. Gabriel and Co., of Birmingham.

Bolton.—At a meeting of the Electrical Tramways Committee of the Corporation on Monday evening, the following information was submitted: as to tramways cost per car mile, exclusive of interest and sinking fund—Bolton, 6·05d.; Hull, 4·47d.; Dover, 5·51d.; Leeds, 5·97d.; Bradford, 6·22d.; Glasgow, 6·26d.; Liverpool, 6·6d.; Blackburn, 6·82d.; Halifax, 8·70d.; Sheffield, 10·9d.; and Blackpool, 11·4d.

Hyde.—The Hyde and Dukinfield Town Councils propose to borrow £75,000 each for the construction of the electric tramway between these boroughs and Stalybridge, which was referred to at length in a previous issue. At the enquiry last week the Light Railway Commissioners granted the order with the exception of the Commercial Brow route, the alternate route along the proposed new road being selected.

Dudley.—Last Friday Colonel Dunlop inspected the new tramway from Dudley to Cradley *vid* Netherton and the reconstructed line from Dudley to the tramway depôt at Sedgley, both of which, within the borough, will be supplied with electricity from the Corporation generating station. The electrical equipment of the lines was inspected by Mr. Trotter six weeks ago, and it is expected that the cars will commence running without further delay.

Cardiff.—Plans have been submitted by Mr. Harpur, the borough engineer, and Mr. Ellis, the electrical tramway engineer, to the Cardiff Tramways Committee for the erection of a power station for tramway purposes, and specifications for the machinery and boilers which Mr. Ellis had prepared have been agreed to. The specifications are for four engines of 500 h.p. each, four 300-kw. generators, and four Lancashire boilers. Tenders are to be advertised for.

Edinburgh.—At a meeting of the Town Council on Wednesday it was proposed that, in view of the electric tramway to be run from Musselburgh to Joppa, and the importance and convenience to the public of a through service to Edinburgh, that it be remitted to the Lord Provost's Committee to consider the whole question of traction between Edinburgh and Joppa, with powers to employ skilled experts and report. The motion, on a show of hands, was defeated by a large majority.

St. Helens.—At the last meeting of the Electric Supply and Tramways Committee the town clerk was instructed to include in the application to the Board of Trade permission to borrow money for the construction of tramways in Corporation-street and Parr-street, the sums required for the construction of the extensions to the borough boundary in Newton-road, and to the boundary in Bold-road from Station-road. The borough electrical engineer was instructed to prepare estimates of the cost of the works indicated.

Kingston.—The Corporation have resolved to oppose a Bill proposed to be promoted by the London United Tramway Company for powers to construct and work electric trams in the borough and in other parts of Surrey. By this scheme the London United Tramway Company propose to lay down trams over about 60 miles of roadway, commencing at Hammersmith and going as far as Esher. There are to be six lines: (1) from Hammersmith, through Fulham, Putney, and Kingston, to Hampton Wick; (2) from New Malden to Kingston; (3) from the Kingston gate of Richmond Park to Tolworth; (4) from Surbiton to Esher; (5) from Thames Ditton to Hampton Court; and (6) from Surbiton to Hook.

Wigan.—At Wednesday's meeting of the Town Council a communication was read from the Pemberton District Council giving notice, under the Tramways Act, 1870, that they required the Wigan Corporation to sell to them so much of the tramways undertaking as was authorised by the Tramways Order, 1879. The matter was referred to the Electric Lighting and Tramways Committee. It was also resolved to ask sanction to the borrowing of £16,500 for electric lighting and power. It was stated, in connection with the construction of the electric tramways, that the work on the section running to Martland Mill Bridge had proceeded fairly rapidly. Difficulties had, however, presented themselves relating to other people. They had not yet been overcome, but it was hoped they would soon disappear, and there would be no difficulty in completing the section within a few days.

New South Wales.—Since the present Government came into office, the construction of the following tramways has been authorised: Spit-road tramway, £15,940; Kensington and Rifle Range tramway, £13,000; Rose Bay to Dover-road tramway, £7,345; St. Peters to Cook's River tramway, £16,850; George-street North to Dawes Point tramway, £18,000; Balmain to Drummoyne tramway, £12,000; Enfield to Mortlake tramway, £17,000; Newcastle-Adamstown tramway, £6,000: Newcastle-Waratah tramway, £5,700; Broken Hill tramways, £18,000. There is considerable stir in Broken Hill as to the character of the tramways which the Minister for Public Works promised them. The suggestion to utilise steam motors from Sydney after the conversion of the trams here does not at all commend itself to a section of the inhabitants, who demand nothing short of an up-to date electrical system.—*New South Wales Railway Budget.*

Digitized by Google

Bradford.—Returns showing the working of the Bradford electric tramways for the week ended Sept. 30 has been submitted as follows: On the Bolton section 3,099 miles had been run, and the receipts amounted to £143. 7s. 10d., equal to 11 1d. per car mile. The workmen's checks issued numbered 1,501, and 1,476 had been returned. The total receipts since April 1 amount to £4,044. 4s. 10d., or 11 57d. per car mile. On the Horton section during the past week 6,352 miles were run, and the receipts were £296. 13s. 4d., which is equal to 11·2d. per car mile. The workmen's checks issued numbered 1,735, and 1,733 were returned. The total receipts since April 1 amount to £8,813. 5s. 10d., which is equal to 12·4d. per car mile. On the Lidget Green section 2,700 miles had been run, and £131. 16s. 10d. taken in receipts, which is equal to 11·34d. per mile. The total receipts since the commencement amount to £632. 7s. 2d., which is equal to 12·31d. per mile.

Wandsworth.—The District Board of Works have adopted the General Purposes Committee's report on the notice of intention of the London United Tramways Company, Limited, to apply for powers to construct tramways through Putney High-street and Upper Richmond-road, Putney. The committee state that they had also considered a letter from the town clerk of Kingston-on-Thames, with reference to the foregoing proposal, stating that the Corporation's Tramways Committee had recommended the Council to offer a determined and unqualified opposition to the company's application, the Corporation having themselves decided to apply in the next session of Parliament for tramway powers, and enquiring whether the Board would also oppose the application of the company. The committee recommended that the company be informed that the Board would be glad to receive any explanation they might desire to submit, and that the Kingston Corporation be informed that the Board or their successors would consider their letter in connection with any tramway scheme that might come before them. This was adopted without discussion.

Croydon.—The County Council have adopted the following report of the Tramways Committee: "The committee do not recommend the acceptance of any tender for the new lines and reconstruction of the tramway track, but recommend that this committee do, in conjunction with the Roads Committee, carry out the work in hardwood, and that they be empowered to advertise for and to accept tenders for the necessary materials and work, and to engage such labour as is requisite for giving effect hereto. The following is a complete list of the estimated cost and tenders accepted and recommended for acceptance of the various works in connection with the tramways: reconstruction of track and paving, £102,000; overhead equipment, less £1,000 extra for lighting purposes (Contract No. 5), £20,045; feeders, test wires, and road-work (Contract No. 4), £12,963; cars (Contract No. 2), £9,670; motorcar equipment (Contract No. 3), £13,052; excavating and guard-wires, £1,400; Thomson-Houston car-shed additions (contract), £4,700; Brighton road car-shed (contract), £4,700; engineer's commission, £3,000; contingencies, £5,000 — total, £176,530. The committee also recommend that application be made to the Board of Trade for their consent to the laying of double lines of tramway from The Swan and Sugar Loaf, South Croydon, to the borough boundary at Purley, and from the Thornton Heath pond to the borough boundary at Norbury. Read letter from the British Electric Traction Company, Limited, stating that they are prepared to agree to the Corporation themselves carrying out the construction and reconstruction of the permanent way and to pay 6½ per cent. upon the reasonable cost of the work, it being understood that the maximum sum upon which such percentage shall be calculated shall not exceed £108,000, which was approximately the amount of the lowest tender, and that it is to be understood that if the Corporation should effect any saving and be able to complete the work for a less sum of money than £108,000, then that the company as lessees shall only be debited with 6½ per cent. upon any total sum less than £108,000, and suggesting that this understanding should be confirmed by a resolution of the Council. The committee recommend that the Council do pass a resolution accordingly."

COMPANIES' MEETINGS AND REPORTS.

HALIFAX AND BERMUDAS CABLE.

The report of the directors for the year ended June 30, adopted at the meeting on Friday last, states that the net result of the year's working is a profit of £3,795, as compared with £10,142 for the previous year. An interim dividend of 2½ per cent. has already been paid, and it is now proposed to make a further equal payment, which will together absorb £2,500, and leave £1,295 to be carried forward. Offers for the sale of debentures to the trustees were invited in December and June last, and £5,197 was paid for £5,200 of debentures, which amount has been written off capital expenditure.

DIRECT WEST INDIA CABLE.

The report of the directors for the year ended June 30, adopted at the meeting on Friday, states that the net result is a profit of £5,456 An interim dividend of 2½ per cent. has already been paid, and it is now proposed to make a further distribution of 3½ per cent., which will leave £3,656 to be carried forward. Under the deed the redemption of the Company's debentures commenced in June last and £9,000 of debentures have been acquired and cancelled, which amount has been written off capital expenditure.

HAWAIIAN TRAMWAYS.

The ordinary general meeting of the Hawaiian Tramways Company, Limited, was held on the 2nd inst. at Cannon-street Hotel, E.C.

The **Chairman** (Colonel C. M. Davidson), in moving the adoption of the report and accounts, said that the progress of changing the motive power had been checked by the action of the opposition company in Honolulu. The new electric motive power would be generated by steam.

The report and accounts were adopted and a dividend of 6 per cent. declared.

RECORDING TELEGRAPHS.

An extraordinary general meeting of this Company was held on Monday at Winchester House, Mr. J. A. Sillars presiding. The following resolution was carried: "That the Company be wound up voluntarily, and that a liquidator be appointed for the purposes of such winding up."

The **Chairman** said the new company—the Typewriting Telegraph Corporation—had been successfully formed, and he congratulated those who were holders of its shares. The first meeting of that company would take place on the 4th inst., when the chairman, Sir James Fergusson, who was a former Postmaster-General, would have an interesting statement as to the invention to lay before the shareholders.

PROVISIONAL PATENTS, 1900.

SEPTEMBER 24.

16312a. Improvements in and connected with wireless telegraphy. Charles Edwin Wilson, 24, Southampton-buildings, Chancery-lane, London. (Date claimed under Patents Rule 19, June 5, 1900) (Complete specification.)

16966. Improved electromotor. August Emil Sauer, 60, Queen Victoria-street, London. (Complete specification.)

16983. An improved electrograph. Wilhelm Carl Emil Faber, 53 Chancery-lane, London.

16993. Improvements in or relating to trolleys for use in electric traction. John George Lister, 111, Hatton-garden, London.

17003. An application of electricity to the imitation of snakes, reptiles, and insects for theatrical and other purposes. Charles Alias and John Joseph Webber, 36, Soho square, London.

SEPTEMBER 25.

17033. An improved electric automatically-indicating target for rifle practice. Percival William Merfield and Edgar Tozer, 33, Chancery-lane, London.

17049. Improvements in coin-operated electric meters. Frank Kraemer and Eugene Weber, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17077. Improvements in arc lamps. Henry Stansfield Dodd and Robert Ironside Bagnall, jun., Norfolk House, Norfolk-street, Strand, London.

SEPTEMBER 26.

17110. An arrangement of connections for sets of electric glow lamps in series so as to maintain the circuit in case of the extinction of one or more of the lamps. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.) (Complete specification.)

17125. Electric generators for military and other cycles. Henry Vander Weyde, 53, Chancery-lane, London.

17128. Improvements in magneto-telephones. Henry Edward Newton, 6, Bream's buildings, Chancery-lane, London. (Parnell Rabbidge, New South Wales.)

17131. Improvements in and relating to incandescence electric lamps. Charles Alfred Henry, 55, Chancery-lane, London.

17135. Improvements in electrodes for accumulators. Herbert John Haddan, 18, Buckingham-street, Strand, London. (Richard Goldstein, Germany.)

SEPTEMBER 27.

17154. Improved mode of attaching glass shades to electric light and the like fittings. James Armsby Ellis, 34, Castle street, Liverpool.

17160. Improvements in electrical fuse boxes. Arthur Denby Smith, Sunbridge-chambers, Bradford.

17172. Improvements in electric switches. Vittorio Giovanni Lironi, Luna Electric Works, Harpurhey, Manchester.

17174. Improvements in carbon brush-holders for dynamos. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.) (Complete specification.)

Digitized by Google

17164. Improvements in electric switches. James Mitchell Hewitt and William Gould Rhodes, 46, Lincoln's-inn-fields, London. (Complete specification.)

17194. A fusible alloy specially adapted for use as an electrical circuit breaker. Richard Pearson, 53, Chancery-lane, London.

SEPTEMBER 28.

17211. Improvements in electric conductor casings or conduits. Louis Marsh, 15, Water-street, Liverpool.

17234. Improved means for generating variable electro-motive force. James Edgar Miller, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, March 1, 1900, being date of application in United States.)

17246. Improved prepayment of electricity meter with coin-freed control mechanism. Benedetto Avena, 322, High Holborn, London. (Complete specification.)

17262. Improvements in electricity meters of the electrolytic type. Arthur Wright and the Reason Manufacturing Company, Limited, Norfolk House, Norfolk-street, Strand, London.

SEPTEMBER 29.

17289. Improvements relating to automatic electric switches. Arthur Henry Adams, 34, Castle-street, Liverpool.

17294. Improvements in or relating to electric telegraph or telephone instruments. Alfred Julius Boult, 111, Hatton-garden, London. (Alexander Bannerman, South Africa.)

17310. Improvements in apparatus for the generation and electrolytic application of electric currents. Francis Edward Elmore, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Partly by John Oliver Surtee Elmore, India.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on Oct. 20.

1899.

19189. Means and apparatus for electrically working vacuum and air pressure railway brake. Siemens Bros. and Co., Limited. (Siemens und Halske Aktien-Gesellschaft.)

24116. Electric accumulators. Perrin.

25767. Electric motors. Rowntree.

1900.

12063. Dynamo-electric mine exploders or apparatus for firing explosives. Wetter. (Gomant.)

14288. Electromagnetic apparatus for jacquards. Szczepanik and Kleinberg.

NOTES.

Institution of Electrical Engineers.—We are informed that the first meeting of the new session of the Institution of Electrical Engineers will be held in the rooms of the Institution of Civil Engineers at 8 p.m. on Thursday, Nov. 8, when the premiums for the session 1899-1900 will be presented, and the president, Prof. John Perry, M.E, D.Sc., F.R.S., will deliver his inaugural address.

Institution of Mechanical Engineers.—We notice that the first monthly meeting of this institution is to be held on Friday evening, Oct. 19, at 8 p.m. The paper to be read on that occasion is one on "Observations on an Improved Glass Revealer for Studying Condensation in Steam-Engine Cylinders and Rendering the Effects Visible," by Mr. Bryan Donkin. The points to be dealt with in the paper include a general description of the revealer, the size of condensed globules, fog in the revealer, condensation on the cast iron, from the low-pressure cylinder, appearance of condensation when fixed of the high-pressure cylinder, fall of temperature in metal cylinder on a jacketed factory engine, the measurement of radiation, etc. A communication is also added from M. Nadal, Ingenieur des Mines, France.

London University.—The election of the members to erve on the senate of the university was proceeded with on Tuesday, when the following gentlemen were elected: Persons nominated for election by the registered graduates in arts—John Fletcher Moulton, M.A.; John David McClure, B.A.; Sir Albert Kaye Rollit, LL.D., B.A.; Thomas Bateman Napier, LL.D.; James Bourne Benson, LL.D., B.A.; Thomas Lambert Mears, LL.D., M.A. For election by the registered graduates in laws—Sir Herbert Hardy Cozens-Hardy, LL.B., B.A. For election by the registered graduates in medicine and in surgery—Thomas Barlow, M.D., B.S, B.Sc.; Frank Joseph Payne, B.Sc. For election by the registered graduates in science—Sir Philip Magnus, B.A., B.Sc.; Sophia Bryant, D.Sc.; Charles William Kimmins, D.Sc.; Frank Clowes, D.Sc.; Silvanus Phillips Thompson, D.Sc., B.A.; Francis Sowerby Macaulay, D.Sc. For election by the registered graduates in music—Joseph Watson Sidebotham, Mus.Bac. (Oxon).

Cable Splicing.—Mr. T. J. Tighe contributes to the *Electrical Review* of New York a description of a method which has been invented for splicing large feeder cables by the Splice and Terminal Company, of New York. The apparatus is made with various pressures, that described being capable of giving a pressure of 20 tons. It consists of an independent hydraulic pump and flexible connection, and though easily capable of exerting the above-mentioned pressure, the press alone with its splicing dies weighs only 14lb. The pump weighs 15lb., and the connector and couplings less than a pound. The size of cable taken in this press is No. 0, or smaller sizes, and it is stated that it is very useful for the work of wiring buildings, it being able to joint the wiring all through the house without using any solder, applying any heat, or damaging the insulation. The whole outfit weighs less than the ordinary solder pot and furnace, and wires of different sizes can be spliced. The apparatus is also useful for attaching terminal blocks for switchboard work to cables.

The Central London Accident.—The most lamentable accident which occurred last Saturday on the Central London Railway was in every way to be regretted. The accident was one for which the unfortunate man who was killed was alone responsible, and he must have opened the gate and have been looking over the side of the train when it occurred. It is well, however, to point out that this accident was one which could not happen to passengers. From a passenger's point of view the railway is absolutely free of some of the risks which are found on the ordinary steam lines. Thus there could be no danger of a door flying open and precipitating a passenger on to the metals, as the doors do not open on to the line, and, apart from this, are carefully closed between each station. Another good thing in this system is that when trains are entering or leaving a station the gates do not stand open ready to knock under the train any passenger who approaches a little too near the edge of the platform, or at least bruise him badly. It is a great pity, therefore, on one of what may be termed the safest of railways, that a fatal accident should have occurred within so short a time of the date of opening.

The Chicago Automobile Exhibition.—The International Automobile Exhibition and Race Meet, held at Washington Park, Chicago, recently, is described in the *Electrical Review*. The race events were, we learn, on the first day, nine in number, and included a one-mile race for electric vehicles alone, and a 10 mile race for any vehicle. There was only one entrant for the former race, Mr. C. A. Lindstrom, who went over the course in an electric runabout in 2 minutes 34 seconds. An American gasolene vehicle won the 10-mile race. A very interesting event on the fourth day was a contest between two electric vehicles. In this contest again the Hewitt-Lindstrom vehicle, driven by Miss Lindstrom, who is only 13 years of age, won the first mile in 1 minute 57 seconds, and the second in 1 minute 59¾ seconds. Other races also took place, amongst these being a backward race for locomobiles. The prize for the vehicle carrying the greatest number of seated passengers also went to the Hewitt-Lindstrom Company for an electrical omnibus. The exhibits at the exhibition included a large number of steam, electric, and gasolene vehicles, there also being shown accessories of all kinds.

The Paris Exhibition Awards.—Our contemporary, the *Electrical World*, calls attention to a curious case of prodigality of awards in connection with the Paris Exhibition. Perhaps it would be more correct to say it is a case in which a single award has been shared by a large number of firms which have comparatively equal rights, and hence may each consider themselves recipients of the grand prix. The exhibit in question was in the liberal art section, where some two or three hundred American journals were exhibited together, being represented by bound volumes. We gather that the company which issues the *Electrical World and Engineer* had, or ought to have had, three exhibits in this bookcase, and it has accordingly received three intimations that it is entitled to use the grand prix amongst its qualifications. These volumes, it appears, were not actually in the bookcase—but to a French jury that is qui e a detail. The owners of the volumes hope that in due time they will be able to find the packing case in which their exhibit was dispatched. The French railways seem to have had an exceptional opportunity of losing consignments during the past year, and to have utilised this opportunity to the fullest possible extent.

Grantown-on-Spey.—As will be seen from our advertisement columns, the Town Council of the burgh of Grantown-on-Spey wish to have the electric light introduced on the most favourable terms to the inhabitants, and that without incurring financial risks. They accordingly have advertised for tenders from contractors for the establishment of such works and the running of the same, and propose, subject to other conditions being equal, to give

Digitized by Google

their support to the company who will supply at the cheapest rates and will give the most favourable terms for repurchase. The small number of inhabitants (1,500) makes the lighting scheme a comparatively small one, but we are assured that the population is largely augmented in the summer and autumn by visitors. The electric light would have quite a free field, as the gas undertaking which used to supply the town suspended operations about two years ago. This seems to be a case in which the course taken is an advantageous one to all concerned, and we presume that a provisional order would be dispensed with and an agreement entered into between the company and Town Council. With overhead wires and economic management, no doubt a fair return may be earned on the capital expenditure.

"The Chamber of Commerce Journal."—As one would expect, with the October issue of the *Chamber of Commerce Journal* is published a supplement containing a report of the proceedings at the meeting of the association of Chambers of Commerce, which was held in Paris from Sept. 5 to 8. Amongst the subjects of particular interest that were discussed we notice that of lighthouse communication, on which subject a resolution was carried to the effect that the association was of the opinion that arrangements should be made without delay for connecting all lightships and isolated lighthouses with the shore by means of wireless telegraphy, and the association regretted that, pending the decision of the Inter-Departmental Committee appointed by the Board of Trade, the installation between the South Foreland lighthouses and East Goodwin lightship was allowed to be removed. On the question of Imperial telegraphic communication the association decided to give every support to the House of Commons Committee appointed to investigate the matter. A resolution was passed urging upon the Postmaster-General the necessity for underground telegraphic communication between the larger towns and seaports to prevent interruption being caused by gales, etc. The discussion on the question of the cheapening of telegrams was adjourned until the spring meeting.

The Telegraph Service at the Paris Exhibition. *Journal Télégraphique* publishes a plan showing the postal and telegraphic service which is in use in the Paris Exhibition. There are, we learn, eight offices placed at the disposition of the public at the Exhibition, one of these being a central office and the others sub-offices. The whole are under the direct direction of the chief of the postal and telegraph services in Paris. The offices undertakes all postal, telegraphic, and telephonic business, having special accommodation for the latter. Besides the telephones in the post offices there are a number of telephone cabins in the grounds, the total number of these, including eight at Vincennes, being 82. Telegrams are received by all the post offices, but are only distributed from the central office, except in the case of Vincennes. Telegraphic business is conducted during the whole time the post offices are open. Telegraph wires connect each of the offices with the central office, and each office contains a Morse instrument; in four of them also being two Hughes instruments. The pneumatic telegrams which are sent from one office to another in the Exhibition have reached the high number of 26,000 in one day. There are 38 messengers employed for distributing the telegrams. As regards the telephone service, the public can communicate from any of the 82 telephone cabins with any part of Paris, or with any district connected to Paris by telephone. Season tickets are issued for these telephonic cabins by which one can use the lines to communicate with subscribers in Paris, the tickets costing about 16s., and being available as long as the cabins remain working. The telephone cabins are open from 7 a.m. till 11 p.m., and have each two attendants.

Electric Lighting at Stroud.—From a report which we have received from a local source, we gather that the Urban District Council held a special meeting to consider the advisability of applying for a provisional order for the electric lighting of the district. We gather from the remarks made by the chairman that he did not take an active part in the organisation of the meeting, as he does not support electric lighting being carried out at the present time. He stated that Stroud had a population of 5,000, and that it would cost £30,000 to provide an electric lighting system. The alternative course which he suggested was one with which we disapprove *in toto*. It is that they should spend a small amount of money now in order to get the matter into their own hands, and then do no more for the present. The sum suggested to be spent—£150—could only refer, we fancy, to the obtaining of a provisional order, and we trust that if the meeting, which is now adjourned, agrees with the chairman, and applies for an order on the lines suggested, that the discussion in the Council will be forwarded to the Board of Trade. If the Urban District Council of Stroud is not prepared to undertake the supply of electric light, which need not cost in such a small place anything like the figure suggested, they ought to withdraw entirely from the matter, and make arrangements with a company for the lighting of their district. The suggested dog-in-the-manger policy will, if carried out, ultimately cause considerable inconvenience to the townspeople generally.

Central Technical College.—The Old Students' Association of the City and Guilds of London Central Technical College held its third annual dinner on Tuesday, Oct. 2, at the Restaurant Frascati, Prof. O. Henrici, LL.D., F.R.S., dean of the college and president of the association, taking the chair. Amongst those present were the professors of the college, Sir A. R. Binnie (who had in the afternoon given the inaugural address at the opening of the college session), and Mr. A. L. Soper (assistant secretary to the institute), in addition to a large number of old students. After the toast of "The Queen" had been duly honoured, the Chairman rose to offer the suggestion that in future some business should be taken in connection with the dinner. The toast of "The College" was ably proposed by Mr. M. J. P. O'Gorman, who praised the occasion as one eminently calculated to make the members lose that awe of their professors which they had held in their student days, and laid great stress on the duty of successful old students to help on the younger members, and do all in their power to bring forward the name of the college. In replying to the toast, Prof. Henrici said that the college took the greatest interest in its old students, and pointed out the importance of having a large and efficiently organised Old Students' Association. Prof. W. E. Ayrton, in toasting "The Association," laid special stress on the establishment of an old students' register, and said that it should be the aim of all the members to make their association a miniature empire. Mr. E. F. Armstrong, replying on behalf of the association, in the unavoidable absence of the hon. secretary, sketched briefly the work of the association, and appealed to all members to support it energetically, and to forward in every way the interests of the college. Prof. W. C. Unwin, in proposing "The Visitors," gave an interesting account of what some of the old students were doing. Sir A. R. Binnie and Mr. A. S. E. Ackermann also spoke.

An Electric Exerciser.—A combination medical coil and exerciser is the latest novelty from the States. The instrument, which is described in the *Scientific American*,

Digitized by Google

has been placed on the market by the Badger Brass Company, of Kenosha, U.S.A. The machine resembles the ordinary exerciser in appearance, elastic cords passing over pulleys in the usual way. The cords, however, serve as conductors and the handles as electrodes. Somewhat below the middle portion of the board a cell is held in a recess and wired to an induction coil, secured to the upper part of the board, so that the current strength can be increased. The induced current is conducted through the elastic cords to the handle and back again. In order to interrupt the battery current and incite a secondary current in the coil, one of the pulleys is provided with an interrupter, which, in turning with the pulley, automatically makes and breaks the circuit as it passes a contact secured on the pulley block and wired to the secondary coil. The pulley is suspended from a hook forming part of a movable plate which constitutes a circuit controller. When the cord is pulled, the hook-plate is drawn forward against a stop to complete the circuit. When the handle is released, the hook-plate is automatically retracted to break the circuit. A metallic footplate furnished with the apparatus can be placed in the circuit, so that the current can be passed through the body. By means of a conveniently located switch the current can be directed from either hand through the body to the other hand, or by means of the footplate through the body to the feet, or *vice versâ*. By drawing out the slide of the induction coil, the current can be regulated in strength to meet the requirements of all persons. The stimulating effect of electricity has long been recognised by medical men. The physical development resulting from the use of exercisers has earned for the elastic cord machine a wide popularity. The benefits to be derived from an electric exerciser in which muscular exercise is combined with electrical stimulus are, therefore, thought to be so obvious that further comment is hardly necessary.

The Automobile Club. — We have received a memorandum concerning the trials of electrical vehicles which are to take place from Nov. 5 to 9, 1900. To take part in these trials, vehicles must be entered on or before Friday, Nov. 2, the entry fee being two guineas per vehicle per trial. Forms of entry can now be obtained on application to the Secretary, Automobile Club, 4, Whitehall-court, London, S.W. The vehicles entered may be subjected to the following trials: on Monday, Nov. 5, a run over a given course for an unlimited distance on one charge, the driver declaring to the judge when the run is to be considered as finished; on Nov. 6, a course of 30 miles, to include considerable gradients; on Nov. 7, a course of 30 miles of average road; on Nov. 8, a course of 30 miles of flat or nearly flat road. Vehicles may be entered on or before Friday, Nov. 2, for an additional optional trial to take place on Nov. 9, when the run will be over a given course for an unlimited distance on one charge. The driver is in this instance also to declare to the observer when the run is to be considered as finished. The same batteries are to be used throughout the whole course of the trials, and will be under the supervision of the club. The competitors are, however, responsible for the supervision of the charging of their batteries. The energy consumed, the number of passengers carried, and the average speed attained will be recorded on certificates, which will be granted by the club to competitors, but no speed in excess of the legal limit of 12 miles per hour will be recorded or recognised. The competitors must supply drivers for their vehicles, and must provide on each vehicle a seat for an official judge. The routes on which the trials will take place will be within 50 miles of London, but will not be made known to competitors until immediately before the trials. All the vehicles in the trials are to be fitted with reliable and accurate voltmeters and ammeters, which can be read during the trials by the observers, and these meters must be fitted with terminals, by means of which they may be tested by the judges. In entering vehicles competitors are asked to supply, for the information of the judges only, a diagram of the electrical connections of each vehicle. Competitors must agree to accept the rules and decisions of the judges' committee in all matters, and the judges' committee reserves to itself the right to amend the rules affecting the trials.

A Leclanche Cell for Automobiles.—We notice in *L'Industrie Electrique* a description of a Leclanché cell which it is proposed to use for automobile purposes. The electrodes of the cell have a large surface area, the zinc being made in the form of a box, and thus replacing the outside jar and the carbon, being surrounded with a mixture of manganese dioxide and graphite. The electrolyte has been rendered immovable by a kind of gelatine, and cars supplied with these cells have been worked for a month nearly as continuously as ordinary motor cyles. An improvement, however, has been made on this arrangement, and a new model has been made which has a yet lower internal resistance. In this case highly compressed half cylinders of a depolarising material are formed. The material has as its base manganese dioxide and natural pure graphite. Two of these half cylinders are placed in a canvas bag, and there is then forced between their two inner surfaces a carbon stick with a metallic screw head. The two half cylinders when forced apart hold the sides of the bag tightly enough to render tying useless, and the whole forms a solid cylindrical block, which is not easily broken, and of which the cohesion is made even better by being immersed in the exciting liquid. In this arrangement the weight of the depolarising matter for the same volume is double that used with a porous pot of the same size, and this accounts for its longer durability. Generally, in Leclanché cells, the exciting salt must not be very strong, owing to the deposition of insoluble crystals of zinc chlorides on the zincs, but these cells are able to take a very strong solution of hydro-chlorate of ammonia and zinc chlorides. The inventors recommend that the arrangement shall stand in the electrolyte for 24 hours in order that it may soak through the bag and mixture surrounding the carbon, so as to obtain a very low internal resistance. With this cell it is stated that 25 to 30 amperes can be obtained. Our contemporary gives the curves obtained by the discharge of cells of this kind at the electrical laboratory at the School of Physics and Organic Chemistry. The curves represent three different conditions. The first curve was obtained by passing the current from the cell through a resistance of 20 ohms, when after 33 days the difference in potential was still 1·25 volts; the second curve illustrates a test in which an external resistance of 10 ohms was used, when the results were not so good, the difference being about ·8 of a volt; with a five-ohm resistance the value for the same line was about ·45 volt. The current furnished in each case was 52·5 amperes, 87·9 amperes, and 127·6 amperes respectively, thus showing that the capacity of the cell is great enough for the majority of the applications to which it would be put.

The Central London Railway.—In our last week's issue will be found some interesting figures as to the success obtained by this railway in providing a good and efficient means of communication between one of our great London suburbs and the heart of the City. We did not in it refer, however, to the extraordinarily low fares which are charged in comparison with those which obtain on other

Digitized by Google

lines which give communication between the same parts. One result of these low fares has naturally been a tremendous rush of traffic morning and evening, as such a large number of workers in the City have been induced, on the score of cheapness, to travel on the new line. In consequence of this rush there has been overcrowding, and it is interesting to read the untechnical advice given in the daily papers as to the way in which this overcrowding should be overcome. We have noticed particularly that the *Times* has opened its columns to most impracticable suggestions, amongst which was one that during the morning rush both of the tunnels should be used as up lines, and that again in the evening they should be used both as down lines. The writer in this case did not go into the question as to what was to happen to the trains after they got to the City in the morning, nor state that with a three minutes' service and a continuous run in one direction only even for an hour, instead of two hours, as suggested, would mean that 80 trains would have to be provided, each one of which would only be working for a single journey in the course of at least 2½ hours. The capital charges would of course be prohibitive, as would also the cost of the miles of sidings which would have to be constructed at the Bank. Another suggestion which would certainly have the effect of making the line more convenient in the early morning to those who wish to come into the City, is given in the *Times* of Tuesday last. The writer suggests that, instead of providing for the demand, it should be killed by increasing the fares during the time of rush. In other words, that the company should refuse to carry out its parliamentary obligations, and also fail to fulfil the very object for which the line was designed. The only solution of the difficulty is a more frequent train service, and this the company are arranging to give as quickly as possible. It will be quite recognised that with a new venture such as the Central London, the maximum carrying capacity cannot safely be obtained in the early days of running without the risk of sacrificing continuity of service.

The Smoke Nuisance.—We notice in last week's *Lancet* a letter from Sir W. B. Richmond, of the Coal Smoke Abatement Society, in which he states that this society is by no means moribund. From this letter we are surprised to hear that the London County Council and the various vestries and parish councils in Greater London have shown great negligence and apathy in dealing with the smoke question. From the number of references we have given in our columns, we had believed that the reverse was the case, and that several of these vestries carried their smoke prosecutions to an absurdity. Still, the Coal Smoke Abatement Society thinks that there is no chance of improving matters until the police are again made responsible for the prosecutions. Sir W. B. Richmond states that "jobbery is rife and bribery constant. The reports which our inspectors have laid before the County Council, parish councils, and vestries have been ignored or given the lie by these bodies." It is evident from the above that the society with its two inspectors is rather sore that its efforts to improve the conditions of life are not more highly appreciated by the other authorities who have this work in hand. We think, however, that Sir W. B. Richmond should moderate somewhat his language on the subject, and should also make sure from personal experiments carried out by his two inspectors that his own chimneys do not smoke. While we agree that certain manufacturers in London do cause some considerable nuisance from smoke issuing from their chimneys, it is the domestic fire which is often the chief offender. The smoke issuing from a chimney is judged by the blackness when looking through it to the sky, and this is, of course, in proportion to the size of the orifice through which the smoke issues, provided that it carries equal quantities of soot in a given volume. When judged in this way, therefore, the small domestic will pass the test, whereas a large factory chimney, sending out no more smoke per cubic foot of gas, will appear to be a great offender. In the same issue of the *Lancet* a gentleman who signs himself "L. R." complains terribly of the nuisance caused by the chimney of the South London Electric Lighting Corporation. It will be remembered that this company burns the refuse of the parish of Lambeth, and that it has been fined for the nuisance caused on several occasions. This the correspondent admits, but he joins with the previous writer in insinuating that the Lambeth Vestry do not prosecute the company more frequently because the company is burning the ashbin refuse of the parish. It is a great pity that these advocates of purer air cannot conduct their crusade against the smoky chimneys without blackening the characters of public men in London.

Military Hospitals.—Much has recently been heard about the management of the hospitals in which during the past year the sick and wounded of our troops have been placed. It is interesting, therefore, to find in the *Lancet* descriptions of some of the South African hospitals, which have been sent in by correspondents who have actually been in the buildings, and who understand whether the best is being done for the soldiers. Thus, in speaking of the hospitals in the Transvaal, a correspondent says that without question that at Johannesburg is one of the best. At Pretoria, which is practically the headquarters of the army, there is provision made for about 2,000 beds. These are placed in three hospitals placed side by side on the plain east of the town and near the railway. The hospitals, which were erected by the Royal Army Medical Corps, consist of tents. Of these three, No. 2 General Hospital is mentioned as being the best of its kind during the war, and it is one of the few hospitals possessing a disinfector for bedding. It is provided with a telephone and electric light for the central avenues of the camp. This latter fact should be gratifying of electrical engineers, and one is tempted to ask whether the electric machines were "commandeered" from the slim Boer. The Palace of Justice, which was converted into the "Irish" Hospital, has also received a large amount of praise for its admirable arrangements. Sir W. Thompson, who organised this hospital, also installed electric lighting in the building, and it is stated by our contemporary's correspondent to be a hospital which is hard to beat, if one remembers that the building was not constructed for a hospital. What, however, seems likely to become the best hospital is that recently opened by Lord and Lady Roberts. It is a yeomanry hospital, and is erected on an estate which was commandeered for the purpose. The estate, which has an extent of 130 acres, belonged to a rebel English burgher who had enriched himself by plotting against England with the Transvaal Government, and who introduced among the Boers the soft-nosed bullets and other similar infringements of the rules of war. His house is situated on a hill which catches fresh breezes when Pretoria itself is misty and sultry. Fifty patients are accommodated in this residence, which now has an operating theatre, 40 nurses being also provided for in two neighbouring houses. The remainder of the patients, to the number of 400, are placed in marquees. In the principal house electric light has again been installed, and the hospital was prepared and in readiness within the short space of 12 days. We are glad to see from the above descriptions, and others which are given in the *Lancet*, that wherever it is possible electric light is installed. This must add greatly to the

Digitized by Google

comfort of the sufferers, and at the same time render the tasks both of doctors and nurses a great deal easier and more pleasant than would otherwise be the case.

Editing.—We can quite understand any journal devoted to science inserting extracts from unscientific publications in order to show what great mistakes can be made from incorrect descriptions and misrepresenting facts, but we fail to see why a paper like *Invention* should insert, under the heading of "Electrical Dangers," extracts from an insurance journal which are absolutely unintelligible. The insertion may please the popular taste, and we can only assume, not having seen the insurance journal in question, that the editor of *Invention* was impressed by the incomprehensibility of the statements. Why he could not frankly say so we do not know, and we certainly do not credit the statement at the end that every electrical engineer and expert knows such mishaps are inseparable from the systems. The paragraph we complain of reads as follows: "An insurance journal gives 40 or more instances of novel troubles and disasters attendant upon the omnipresent conducting electric wire. Not the ordinary, readily understood trouble that results in severe shocks, or death tragedies, or fire scares and fire loss, but of incidents of unexpected demonstration and phenomena that not even experts could anticipate and provide for to guarantee safety of person and property. Defective wiring, severed current, surcharged conductor, broken or disjointed insulator, disordered switch, tremendous voltage, deadly third rail, etc.—all are such common sources of annoyance and injury as to command but passing notice, and death or destruction that may ensue are relegated to the category of accidents due to avoidable or easily-corrected conditions. But there is a long line of haps and mishaps associated with light and power distribution at once curious, mysterious, and alarming, and which greatly adds to public distrust of the 'harnessed lightning.' As, for example: A man engaged in pressing trousers with an electric iron using alternating current made a ground contact somehow, and was instantly killed. Current of series arc circuit grounded through porcelain. Arc was established and ignited insulation. Fire communicated to wooden beam. A young man standing upon a register of a hot-air furnace attempted to turn on an incandescent lamp; primary and secondary circuits of transformers were in contact. He somehow escaped death, but several toes on one foot and the thumb and forefinger on one hand were so badly burned that they had to be amputated. Two-wire circuit run on wooden moulding in a damp place, fastened to a brick wall under sidewalk. Fire caused by accumulation of sodium salts. During violent thunderstorm lightning discharge entered office building over signal circuit. Insulation took fire, and fire communicated to lighting and other wires in a vertical shaft used as a runaway. Woodwork in shaft consumed. Overheated rheostat set fire to adjacent woodwork, having been placed too near latter. Fire spread rapidly." We believe, from the words used, that the insurance journal was an American one, but surely this ought to have been stated in an English paper.

Quebec Electric Railways.—Mr. D. E. Blair read before the Canadian Electrical Association at their recent meeting a paper dealing with the electric railway system in Quebec. He stated that the city had a population of 75,000, of which 65,000 were French Canadians. A large percentage of the population were not only limited in means, but lived in congested districts near their employment, and had but little need for street cars. The life of the city was a very easy-going one, haste in getting about being considered unimportant. The very heavy snowfalls also militated against the success of an electrical tramway undertaking. The Quebec Railway, Light, and Power Company, however, started work, and soon had a street railway in successful operation. The work of tracklaying was started on Nov. 1, 1896, and by July 1, 1897, the road was open for traffic. The track was constructed of 72lb. 6in. T-rails in 30ft. lengths, laid to standard gauge on 7in. ties at 2ft. centres. Each joint was double bonded, and there were double cross-bonds every 150ft. The total length of the track is 17½ miles, of which 7¼ miles are single and 5⅛ miles are double track. The poles are tubular iron ones, 28ft. long, and placed 90ft. apart. The trolley wire is No. 00 hard drawn, and the lightning arresters are of Wurts's non-arcing type. There are two car-sheds, the repairs being done in one of these, in which are seven floored pits communicating with the workshops underneath. The streets in Quebec are very narrow and winding, there being hardly room for a cart to pass an electric car on a single track. The return track comes through a very difficult part of the town, on one mile section there being no less than 11 curves of from 35ft. to 40ft. radius. The upper and lower towns, which are at very different elevations, are connected by two lines, ascending obliquely along the face of the cliff, one of these lines rising 172ft. in a length of 3,440ft. This is an average grade of 5 per cent., but certain sections have grades of 12½, 10, and 9 per cent, others being level. All these grades have sharp curves. The other cross-line has an average grade of 6·8 per cent., and is carried along part of the cliff by a steel trestle at a grade of 7·5 per cent. On this line, when a car leaves the trestle to take the up-grade, it is running at half-speed, and must be accelerated on grade, this being a heavy drag on the motor. The average speed on all lines is about eight miles per hour, the average number of cars employed being 35 in summer and 30 in winter. Speeds on down grades must not exceed four miles per hour, and hand brakes are used. Soft cast-iron brake shoes are used, this being found to work better than hard cast iron, especially in winter. The cars are 28ft. double-vestibuled closed cars, with a seating capacity of 30. There are also 24 double-end open cars, seating 50 passengers, six snow-sweepers, two way ploughs, and one street sprinkler. The motors are of the Westinghouse No. 12 A 30-h.p. type, the controllers and resistances being supplied by the same manufacturers. The sweeper and snow-plough equipments are necessarily much overloaded at times, the overload often being 100 per cent. for several minutes at a time during heavy storms, and a sweeper will occasionally burn out five or six copper wire fuses, or draw 200 to 250 amperes at 520 volts before it can pass a difficult spot. This does not seem to have any bad effect, beyond the temporary softening of the armature insulation, and sometimes the loss of some solder from the commutator connections. Not a single armature has been burned out since the road was in operation. All closed cars are heated electrically during six months of the year, there being two sections of heaters on each side of the car, each pair being separated by a controller. In four months of the six both sides are in use, but in November and April one side is enough to heat it comfortably. The tramway is operated through a sub-station within the city from a power-house situated at the Falls of Montmorency. The power-house contains three 600-kw. two-phase alternators, one 750-kw. alternator, one 600-kw. double current, 275-500-volt Westinghouse generator, and two 30-kw. bipolar exciters. All the larger machines are direct connected to 52in water-wheels of 1,000 h.p. each, running at 286 revolutions per minute. The sub-station has two 600-kw. two-phase synchronous motors taking current at 5,000 volts, and are direct connected by two 500-kw. 500-volt General Electric railway generators. There are also other lighting machines in the sub-station.

THE EVOLUTION OF SWITCH GEARS FOR HIGH-PRESSURE ALTERNATING CURRENTS.

BY W. E. WARRILOW.

(Concluded from page 492.)

A switchboard constructed on the lines described should recommend itself to engineers who run a number of alternators in parallel, as the machines can be previously plugged up to feed a number of circuits equivalent to their output, and in case of breakdown of a machine or machines they may be isolated at once by opening the 'bus bar interconnector switch. Spare engines can then be run up on the isolated bar, which is subsequently paralleled with the rest of the board. In case of a sudden rush of load, when synchronising is rendered very difficult or impossible, the bars may be separated, and three units run up on each bar quite independent of their synchronism, provided the board is previously arranged for such an event. When the alternators have taken up their load, they may be put in parallel by interconnecting the bars. The circuits would be out a shorter time with this arrangement than if they remained open while machines were being synchronised. The possibilities of connecting two bars together when differing in phase and potential at the 'bus bar fittings by inserting two plugs may bring about unpleasant results, but with ordinary care such chances are very remote. Provided the plug is not withdrawn, the worst that can happen is the blowing of a machine fuse. The advantages of flexibility quite outbalance the disadvantages presented by remote possibilities.

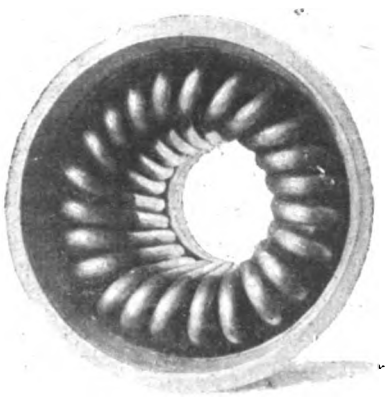

FIG 54.—Proctor-Blaikie Patent Plug Contact.

A board constructed on somewhat similar lines has been recently erected at Bristol. It differs only in the size of the machine panels and in the plugging device for connecting dynamos or circuits to the three 'bus bars. This latter, which comprises a novel form of socket presenting a great number of surfaces to the plug inserted in it, is the Proctor-Blaikie patent plug contact. The adjoining photograph (Fig. 54) illustrates the contact, which is constructed as follows: A hard-drawn copper or phosphor-bronze wire of suitable section is wound round an elliptical mandril, and the coil thus formed is bent so that its longitudinal axis forms a circle. It is then placed in a tube or socket having a hole through the centre capable of taking the required size of plug. The action of pushing the plug into the aperture formed by parts of each convolution of the spring will create a pressure between the plug and the spring and the spring and the socket or tube, while each convolution of the spring acting independently ensures a good contact for all. The pressure of the spring is adjusted by a screw cap (Fig 55) at the top of the socket, which, when screwed in, tends to bulge the elliptical spring, and thus put more pressure on the plug. The carrying capacity of the contact is controlled by (1) gauge of spring wire; (2) number of convolutions that can be accommodated round the circumference of the plug.

Let A = sectional area of wire;
B = number of convolutions;

then effective sectional area of contact = 2 A B.

It will be found that when the diameter of the plug increases, B becomes too small in proportion to the sectional area of the plug. Two contacts may then be arranged in tandem on one plug, or two separate contacts can, where practicable, be put in parallel. Some critics have mentioned that the contact is made by the "touching" of circles, thus only consisting of a number of fine lines. They have suggested as an alternative that wire of rectangular section be used, overlooking the fact that, on their own showing, the contact would still be only of fine lines, as a line also only touches a circle at a point. It has, however, been proved experimentally that the contact offers considerably more surface than the above would tend to show, as the plug soon makes its own flats on the wires. Wire of rectangular section has proved its inferiority when a convolution has twisted out of its place, for the plug has then been scored badly.

Fig. 56 is a photograph of the Ferranti board at Bristol, and its arrangement will be readily understood therefrom. The three 'bus bars are marked "Section 1," "Section 2," and "Hospital" respectively, and an interconnector switch is fitted at the left-hand end of the board to connect the bars together. Current from the three bars is led through wattmeters (seen at the right-hand side of the board) fitted

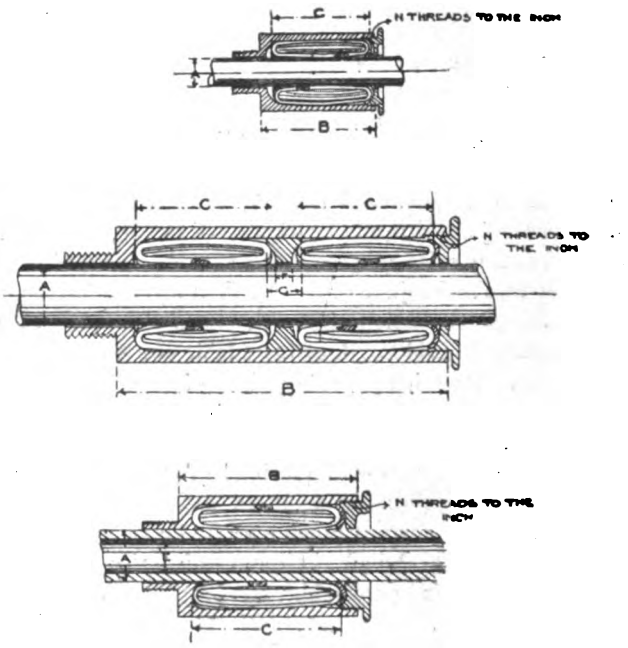

FIG. 55.—Proctor-Blaikie Patent Contact.

each in its own panel, and provided with an ammeter. Two wattmeters and ammeters are capable of carrying 1,000 amperes each, the remaining panel dealing with 500 amperes. Both instruments are provided with short-circuiting devices to facilitate removal while current is passing. The synchronising arrangements possess some interesting features. The alternators installed being of the copper armature type have little or no self-induction, and when by accident machines were switched in a little out of phase the mechanical strains on the plant were great, besides in some instances causing annoyance to consumers by a "jump on the lights." It was therefore suggested that some self-induction should be introduced prior to paralleling, and be gradually removed as the incoming machine pulled into in phase. This was first accomplished in the following manner. A third 'bus bar, called the synchronising bar, was connected to one contact of a synchronising switch, the other contact being coupled to the main 'bus bar *vid* two impedance coils of sufficient self-induction to allow of only 30 amperes passing at 4,000 volts. Each of these coils, which were in series, were provided with short-circuiting switches, and the self-induction could be thus removed in two steps. Paralleling was performed as follows: (1) plug the incoming machine to synchronising bar; (2) when in phase (or nearly so) close the synchronising switch; (3) observe ammeters of running machines and ammeter in series with incoming machine, and when swing has died down short-circuit half impedance; (4) if the parallel is a bad one, a fresh swing will probably be started by this on the ammeters, which will gradually die down until the alternator switch can be closed with impunity.

When the old board was replaced by one of the Ferranti

Digitized by Google

type, the same principle was adhered to with the following modifications: The "half-cock" switch arrangement was enlarged to carry a current up to 30 amperes, the contact being connected to a synchronising bar and switch as above described, having an impedance coil in series. The impedance coil was made in one, and was provided with a mechanical arrangement for raising or lowering the iron core.

A gradual increase or decrease of the inductance in series with the incoming machine could thus be obtained, and the operation of paralleling rendered still more rapid and safe. The energy, however, required to pull two loaded alternators into phase is greater than when they are running light, so that in the case of paralleling sections a high impedance is useless, as it will not pass sufficient energy to hold the machines in phase. This is an error that a switchboard attendant is liable to make if the gear happens to be arranged so that he may use it when paralleling sections. The above system has been in use at Bristol for over six years, and has proved itself eminently satisfactory.

The general flexibility of the Ferranti switchboard has brought it into great favour for high-pressure work, and though it may not represent the last word said on switch gears, it bids fair to maintain its good reputation through

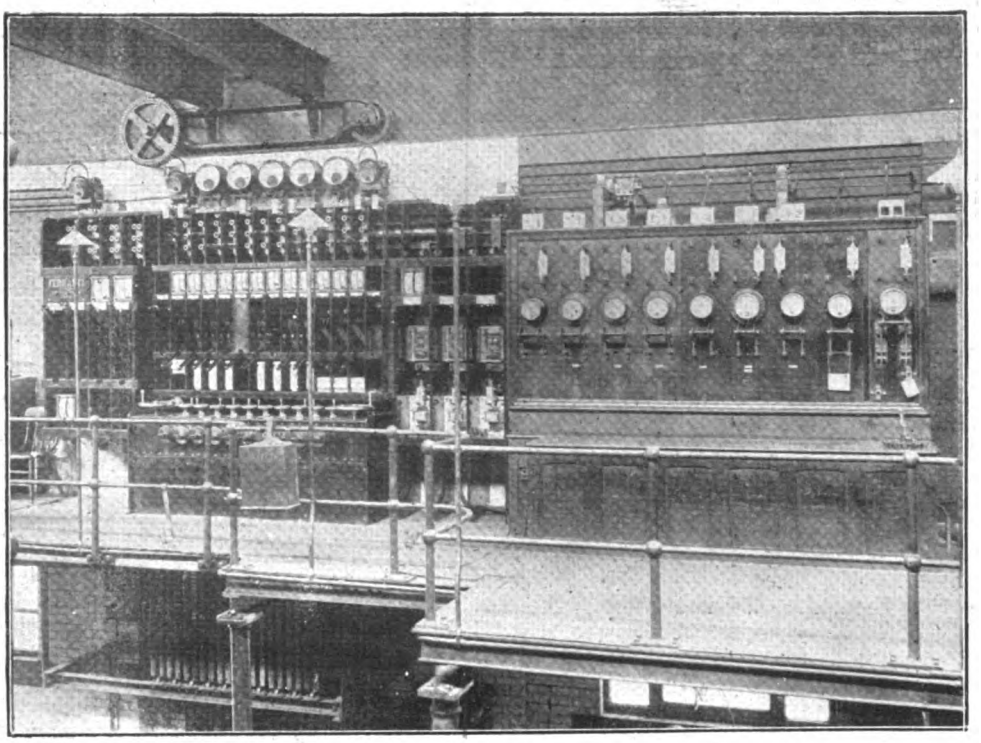

FIG 56. Bristol Main Board.

many years. The descriptions of this gear have been somewhat lengthy by reason of the information to hand. It must not, however, be thought that the above by any means tells the whole tale, as that would fill a volume of no mean dimensions with very interesting matter.

CONCLUSION.

From the foregoing it will be seen that vast improvements in the construction of switch gears have been effected within a very few years, but though the time has been short the changes brought about have been none the less real. One of the greatest factors in the development has undoubtedly been the concentration of so much power in a single generating unit. This circumstance has necessitated the complete remodelling of the switchboard in those stations which were originally installed with plants of small output, and which are extended for the erection of large units. In many cases this remodelling has resolved itself into the supplanting of the old gear by an up-to-date apparatus, as the construction of the former has been such that it were folly to entrust it with the control of heavy currents. Double-pole switch gears erected in wood framings and mountings, connected electrically by rubber-covered cables and composed generally of materials of a more or less inflammable nature, present possibilities which in case of disaster hardly bear thinking upon. It may be said that such boards do exist and fulfil their conditions satisfactorily, but such a statement takes nothing from the aforesaid possibilities, nor is it in any way an excuse for the existence of the board.

In replacing his old board by a new one the station engineer has some difficulties to meet, differing according to circumstances, in making the change. Where the old board occupies the most favourable situation, the erection of the new gear in its place without interrupting the supply will be a matter of considerable difficulty. When this is impossible, the new board must be fixed in as advantageous a position as can be found, as the extension of the old board is but a temporary solution of the problem. Speaking of the situation of the gear, there can be no doubt that it should be placed in a room which is out of reach of all machinery, though commanding at the same time a complete view of the engine-room. Such an arrangement keeps the switchboard, which represents the "vitals" of the station, out of harm's way, and there need be no difficulty in carrying out the control of the alternators when efficient signalling apparatus is employed.

The general improvement of high-tension switch gears has added greatly to the keeping up of a continuous supply to consumers, who are accordingly better pleased, and to the reduction in the number of fatal accidents at the generating station. An all-round popularisation of the electric light has thus been brought about, with corresponding beneficial results. The marked effect thus produced on the electrical industry cannot be over-estimated, as the failures of supply in early days did much to prevent the progress of many concerns. That switch gears were answerable for a great number of these interruptions goes almost without saying, and the improvements effected speak well for the enterprise of those who had the difficulties to overcome and the manner in which they surmounted them.

In conclusion, the author begs to thank those firms whose gears have been described for their kindness in giving him particulars, with photographs and diagrams, of their manufactures, and also to the electrical engineers of Bristol, Huddersfield, and Leeds for their kind permission to reproduce photographs of switchboards in their respective stations.

[By error, Fig. 51, illustrating one of the circuit boards at Huddersfield, in our issue of last week was inserted upside down.—ED. *E. E.*]

A CONTINUOUS-CURRENT DYNAMO FOR WIDELY VARYING VOLTAGES, DESIGNED BY E. LANHOFFER.*

The voltage available at the terminals of a continuous-current dynamo is not capable of wide variation. If one considers a machine revolving at its regular speed and supplying a given current, all that is necessary to increase the voltage at the terminals is to increase the magnetic flux by means of increasing the exciting current. One soon finds, however, the limit in this direction, which is given by the magnetic saturation of the iron in the field magnets. From this cause the magnetic flux cannot be increased above a certain limit, however much the ampere-turns are increased. On the other hand, if one tries to diminish the voltage by reducing the excitation, sparking

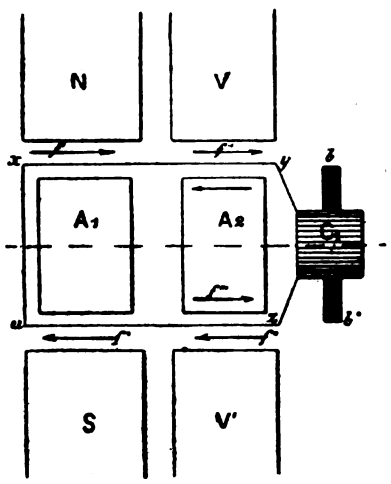

FIG. 1.

occurs on the commutator, because under the then conditions the current through the armature cannot be commutated satisfactorily. The coefficient of the range of potential difference at the terminals of a dynamo is used by the authors to denote that under given conditions of speed and current the machine shall work equally well at either extreme of voltage. In practice this coefficient usually is less than 1·5—that is to say, for example, that a dynamo designed to give 120 volts will not work well over a range greater than from 100 to 150 volts when at normal speed and with its maximum current output. In a number of cases of great interest

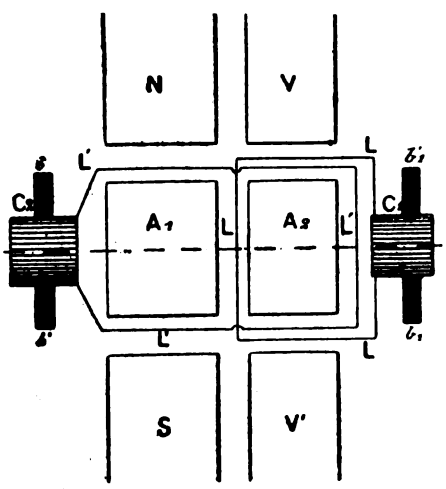

FIG. 2.

machines are wanted which have a higher coefficient than 1·5. The so-called differential dynamo designed by Mr. E. Lanhoffer, in the authors' opinion, completely solves the question. The maximum limit of the voltage of this machine is still fixed by the saturation of the field magnet,

* This article is taken from the columns of our French contemporary *L'Electricien*. In the translation we have had to condense it slightly, but the general arguments of the original article are followed in full.

but the minimum voltage can be made extremely small without resulting in any inconvenience with respect to commutation. The coefficiency of the range of voltage can be made even greater than 5, which is a remarkable result.

The working of the Lanhoffer dynamo depends on the possibility of developing several distinct E.M.F.'s in the various parts of the winding of an armature. If one considers a wire in which there are induced several

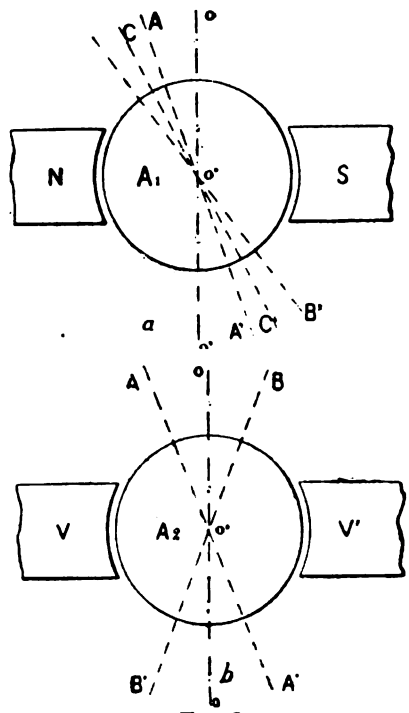

FIG. 3.

E.M.F.'s, the potential difference between its extremities will be equal to the algebraical sum of the elementary E.M.F.'s, which either aid or reduce the resultant according to their respective signs. In order to be able to develop simultaneously the different E.M.F.'s in the same wire, it is quite evident that the various parts of this wire will have to be placed in independent magnetic fields. Practically two fields are sufficient, and the differential machine is composed of two ordinary dynamos placed with their axes

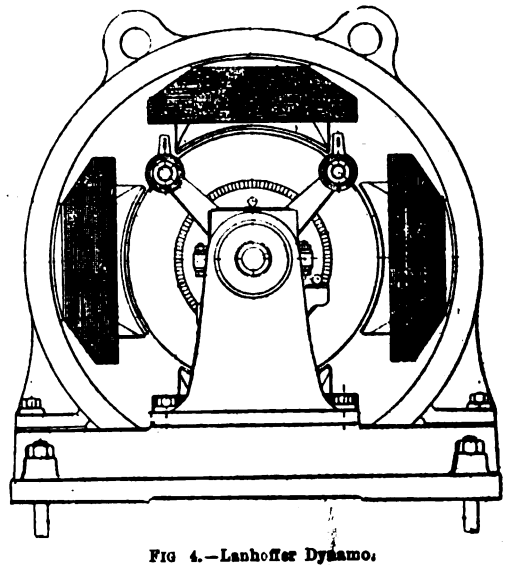

FIG. 4.—Lanhoffer Dynamo.

in the same line, so as to enable a common shaft to be used for the two armatures. The armature cores are thus separated, each being placed in symmetrical relation to its field. The wires on the armature are so disposed that the different turns embrace both these armature cores. Any one wire is thus placed under the inductive influence of two independent fields, which act in reality each independently. When these magnetic fields are in the same direction the E.M.F.'s induced in the machine will add, and the machine acts as

Digitized by Google

an ordinary single dynamo. When, however, the independent magnetic fields are in the opposite direction, the E.M.F.'s oppose one another, and may even completely annul each other's effect. The dynamo thus works differentially.

Again, if one field is not excited, the other acts on the armature core as if the first did not exist. Fig. 1 gives diagrammatically the arrangement of the Lanhoffer dynamo. It will be seen that the magnet poles N S act on the core A_1, while the magnet poles V V' act on the core A_2. The wire, $x y z u$, is one turn of the armature winding. We may call E the E.M.F. developed by the poles N S, and e that due to the action of the poles V V'. Let us suppose that the excitation of the poles N S is constant, and that in consequence E is constant, and is in the direction indicated by the arrows ff, and e is the maximum E.M.F. which can be developed by the core V V'. It is easy to see that the resultant E.M.F. at the terminal will be able to have all the values which lie between $E+e$ and $E-e$. The intermediate values between these two limits will depend on the direction and strength of the exciting current in the coils placed round the electromagnets V V.

If e is positive—that is to say, has the same sign as E—the machine V V will act as a booster, the voltage in the coil being in the direction shown by the arrow f''. If, on the other hand, e is opposed to E, the voltage in the machine will then be as shown by the arrow f''. The ratio of the sections of the poles, N S and V V', determines the relation between E and the maximum E. It fixes in the same way the limits between which one is able to vary the voltage on the collector of the machine. The differential dynamo designed by Mr. E. Lanhoffer, with its two distinct magnet circuits, will act then from the point of view of its maximum output as a dynamo of which the magnetic circuit would be equivalent to the sum of its two parts. The dimensions of the winding will in reality be the same, and the two field-magnet systems ought to be brought as near together as they conveniently can be. The machine can be driven in any way that may be desired.

The regulation of the voltage at the brushes, $b b'$, is effected by means of a rheostat and reverser placed in the circuit of the field magnets V V so that that side of the machine acts as a compensator. The excitation of the magnets N S, which should be constant, can be obtained either by separate excitation, or, preferably, by a special winding, L L, on the armature core A_2. The machine will then be self-exciting, the small supplementary armature winding furnishing the excitation for both systems of field magnets. This arrangement is shown diagrammatically in Fig. 2.

The differential dynamo may equally well be constructed as a transformer of continuous currents of which the ratio of transformation can be varied through very wide limits. Instead of being mechanically driven, the dynamo would then be connected on one side to the source of supply, while the voltage taken off could be varied at will. Fig. 2 would represent this arrangement, if the motor winding, L, was placed over the core A_1, instead of being on A_2, the current from the mains would then go to the motor winding, L, on the core A_1, and would be supplied through the commutator C_1. The excitation for both the sets of field magnets will also be taken from the street mains. The winding L_1, which embraces both cores, and which is connected to the commutator C_2, then gives out the transformed current, the voltage of which can be varied at will by means of the rheostat and reverser in the field circuit round V V'.

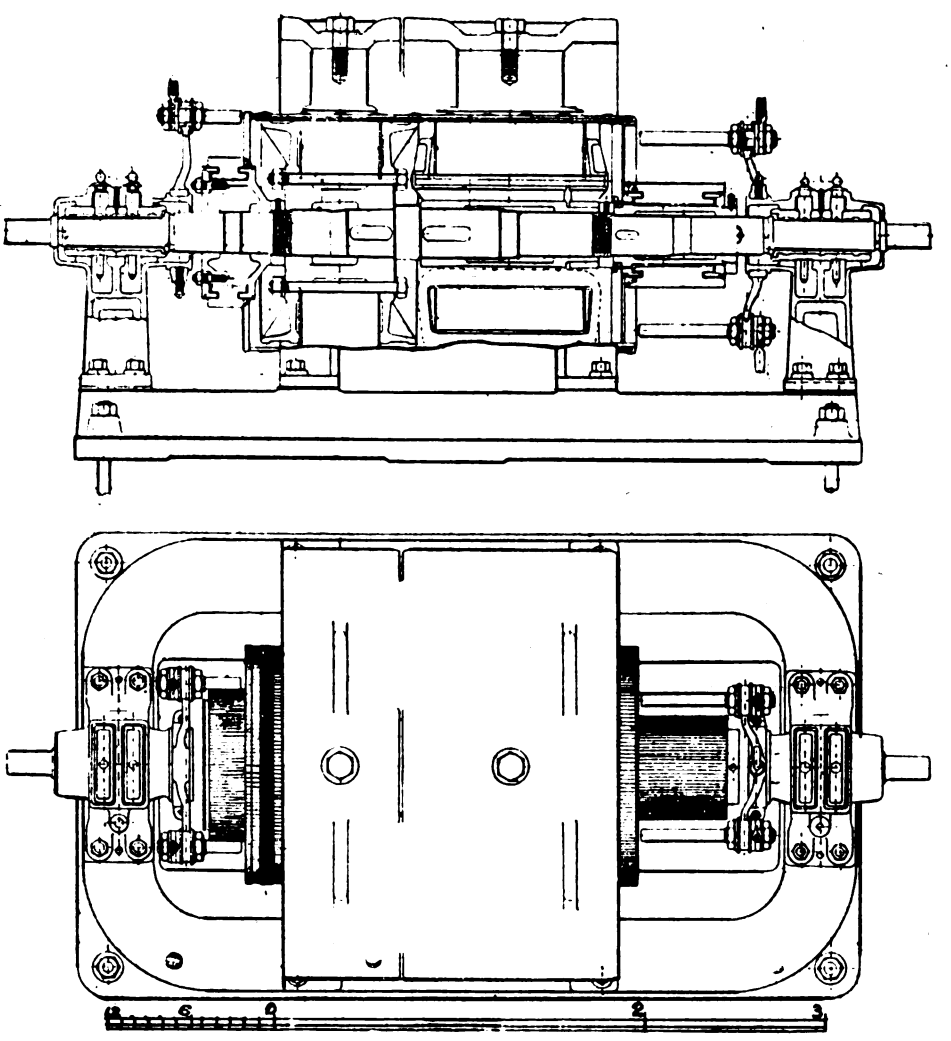

FIG. 5.—Plan and Section showing Details o the Lanhoffer Dynamo.

It is interesting now to consider how the differential dynamo will act as a motor. If this is supplied under constant voltage, it will be able to develop its torque at exceedingly different speeds. This machine with the variable speed will be exactly as represented in Fig. 1. The current from the mains would supply the excitation, and would also feed the commutator C_1. If, then, the electromagnets V V' act in the same direction as N S, the machine

Digitized by Google

will behave as an ordinary motor of the equivalent dimensions. When, on the other hand, the poles V V′ act in the opposite direction to the poles N S, the resultant counter E.M.F. will diminish. The speed of the motor will then augment until the point is reached at which the counter E.M.F. has acquired again a value approximately equal to that supplied, as is always the case in motors. If one denotes by ω the speed of the motor when the poles N S and V V′ are in the same direction and developing the maximum counter E.M.F. $E+e$, then when the poles V V′ act in the opposite direction and produce the voltage $-e$, the total E.M.F. becomes $E-e$. The speed ω' then will have the value $\omega' = -\omega\frac{E+e}{E-e}$.

If, for example, the poles, N S and V V′, had the same section, and were able in consequence to develop exactly the same flux, one could have $E-e=0$, and the speed would then have the value $\omega' = \omega\frac{E+e}{0}$, which would be infinity. This case is only theoretical. In practice the flux developed by the poles V V′ is always less than that from the poles N S, and for this reason the electromagnets V V′ have always a smaller section than that of the electromagnets N S. The limit on the ground of speed is reached by considerations of a purely mechanical order. With smooth armature cores it is hardly possible to go beyond a circumferential speed of 4,000ft. per minute, and if the core is toothed to receive the conductors, which are secured by a dovetail of wood, 6,000ft. per minute may be obtained.

The next point to be considered in the working of this machine is that of the armature reaction with respect to the commutation. If, in Fig. 1, the two sets of field magnets act in the same direction, the resultant flux in the air-space will have its neutral axis at A A′, Fig. 3, for the field-magnet system, N S, of the machine, and along B′ B for the system V V′.

From the point of view for the total armature reaction this will pass as if the reaction flux had its axis along C′ C. For any given load the angle formed by the lines A A′ and o o′ will be constant, while the angle B o″ o varies according to the voltage developed by the compensating machine, V V′. When this voltage is small—that is, when the poles V V′ are only a little excited—the angle B o″ o is greater than A o″ o. It diminishes when the excitation increases, and when the voltage is in the neighbourhood of e, B B′ will be superimposed upon A A′.

In order to get good commutation, the brushes ought to be placed in order to satisfy the two positions A A′ and B B′ situate on the same side of o o. When the electromagnets V V′ act in the opposite direction to N S, the reaction of the flux relative to the machine N S remains, as before, along A A′. The reaction of the flux in the side V V′ passes from B B′ to the other side of the line o o′. From the point of view of the position of the brushes the armature winding placed on the core A_1 demands a lead in advance of the direction of rotation, as is the case in ordinary generators. The lead is, on the contrary, on the reverse side of the axis, as in motors, for that part of the winding on the core A_2.

The only way to satisfy these two positions of leads which are so different, consists in giving the various elements of the machine such dimensions that the brushes are able to rest in one position independently of whether the machine is running as a motor or as a dynamo. It is now known how to construct dynamos which are sufficiently perfect to be able to work well with a fixed position of brushes, whatever may be the output or direction of rotation. With respect to the fall of voltage caused by the armature reaction, the effects are the same in the Lanhoffer machine as in ordinary dynamos which are well known. Each part, A_1 A_2, of the armature acts, in effect, on its own account, and the effects set up in all cases are just what would happen if one had an armature with a single core equivalent to the sum of the parts A_1 and A_2. Let us see now what happens when the Lanhoffer dynamo is wound so as to be a transformer with variable ratios. The armature reactions on the core A_1 will thus counteract the ampere-turns of the motor winding, which we have called L_1, as the reactions are equal and opposite. The ampere-turns of the differential winding on A_2 are the only ones to act, and the resultant flux is its neutral axis along B B′, or following B_1 B_1', according as the poles V V′ act with or against the poles, N S. The armature reaction is less in these two cases, and the commutation still more easy, than when the machine does not use the motor winding, L′, and acts only as a generator which is driven mechanically. The same applies when the differential dynamo is used as a motor with variable speeds. There is still to be examined the case in which the poles V V′ are not excited, and the part of the winding of the armature on the core A_2 does not develop any E.M.F. This case is evidently the most unfavourable, because the winding on the core A_2 carries the whole current before poles which are not excited. In

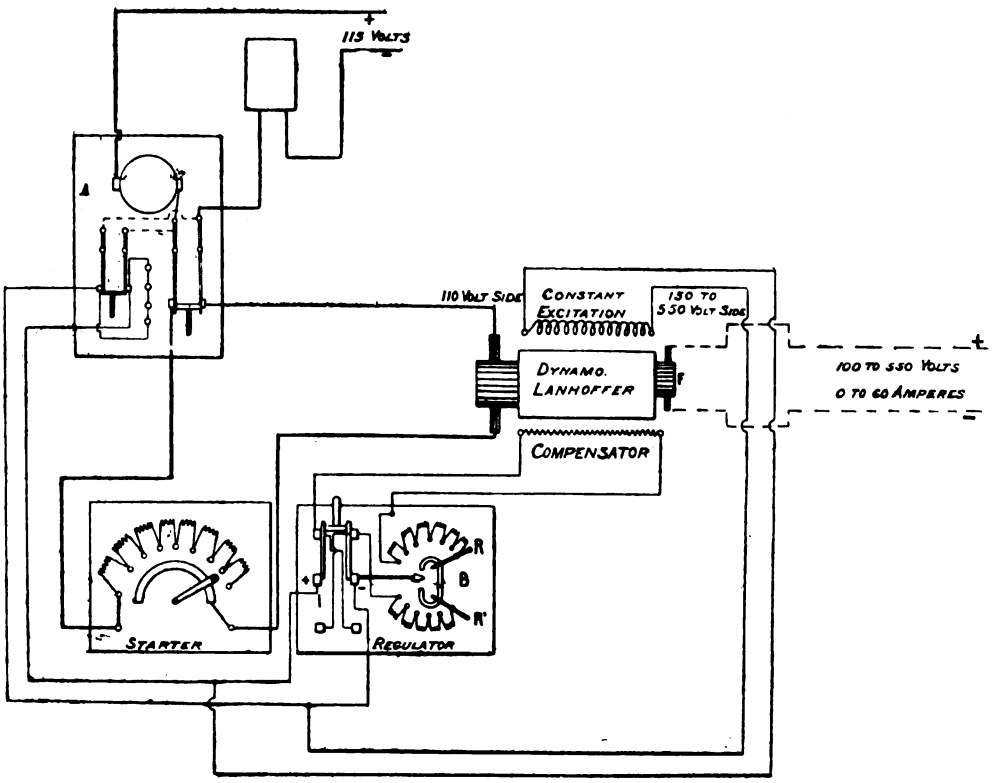

FIG. 6.—Diagram of Connections

Digitized by Google

order that the commutation may not give trouble, it is necessary that a part of the winding, L, should be taken back round the core A_1 only. This shows that the differential dynamo does what cannot be done by mounting in series two independent armatures. The armature which developes a small difference of potential, and which in the meanwhile has to carry the current of the other, would behave very badly with respect to sparking. On the contrary, the arrangement of Mr. Lanhoffer, if one portion of the turn tends to give trouble in working, the rest of that turn opposes it, and practically the machine behaves exceedingly well under all loads, voltages, and speeds. A typical example is the case of a transformer with a variable ratio designed and constructed for the Compagnie du Nord by Le Maison Breguet, who are the licensees in France of the Lanhoffer patents. The Compagnie du Nord lights a great number of trains by means of incandescent lamps run from accumulators in such a manner as to run them independently of each other. According to the method arranged by Mr. Sartiaux, the engineer of the company, the accumulators on those carriages making up a train are charged, while the train is at rest, in groups of batteries in series. This system gives the most economical results, and renders the charging installation exceedingly simple. It has also been approved by long practice. There is, however, one difficulty which is serious, and which results from the number of vehicles on a train varying from day to day according to the requirements of the service. The voltage of charge thus varies from one train to another and from one day to another. On the other hand, various trains are charged in the railway stations possessing electric lighting plant, and there is not, properly speaking, any special station for charging the accumulators on the carriages. In order to keep the advantages and the simplicity of the series charging, it was indispensable to have a machine with varying voltage for the needs of the service. The charging of the accumulators on a train takes from 30 to 35 amperes at a voltage which may vary from 140 to 500 volts, according to the number of carriages. This problem has been solved by the Lanhoffer dynamo. In this case was employed the type of differential dynamo shown diagrammatically in Fig. 1. In certain cases the machines are driven mechanically, and in a great number of workshops which possess no motive power, and which are supplied by transmission of electrical energy at high voltage, it is not possible to drive the dynamo mechanically. In other cases where motors can be attached direct to the dynamo, they were only able to supply these motors at 120 volts. It is in these cases that the transformer with variable voltage, illustrated in Figs. 4 and 5, was used. This machine consists of two laminated toothed armatures on a common shaft, which is mounted on self-oiling bearings. The field magnets are mounted in a cylindrical casting of steel. This cylindrical casting is divided into two halves, as seen in the plan. Six slits are provided, which are not very wide, as can be seen. Each of the machines is of the four-pole type, the poles being vertical and pointing inwards. The dimensions of the machines are given in the article in question, but as these can be taken from the illustrations, we have not reproduced them in full. The over-all diameter of the field-magnet ring is 2ft. 5in. The diameter of the core of the armature is 16in., while its length is 10in. It is wound on the Gramme principle, with three turns of wire in each of the 52 slits from the 52 sections in the commutator. These armature dimensions apply to the receiving side of the motor-generator, but the other side are very much the same, except that the length of the core is 5¼in. At full load the speed of the engine is 1,250 revolutions per minute, and the machine is able to give any voltage from 100 up to 550. The receiving side is fed at 115 volts, as are also the exciting coils. At full load—33 kw.—the efficiency was 82 per cent, which is not bad for this size of transformer. When the machine is driven mechanically, the efficiency is about 91 per cent. Fig. 6 shows the diagram of connections of this continuous-current transformer, together with its accessories for starting and regulating. The dynamo is practically self-centered. The value of E is about 300 volts, while e can be varied to 250 volts, according to the needs of the user. The reversing switch in circuit enables this voltage to be either in the same direction or to oppose the E.M.F., E. In order to vary the voltage between 0 and + or − 250 volts, it is necessary to have a rheostat with considerable resistance. It is more advantageous to excite the compensating side by means of a shunt current taken at a variable voltage between 0 and 110 volts. A rheostat of from 20 to 25 ohms shunted on the 110-volt circuit serves as a potentiometer, and permits a variable excitation to be obtained. The authors of the description, Messrs. E. J. Brunswick and Aliamet, conclude their article with the statement that they need not draw up a list of the advantages of the machine, because anyone can easily understand what can be done with a machine such as is described, which, while exceedingly simple, is able to give great variations of speed and voltage for continuous currents.

N.B.—A careful reading of the above article will show that the author's claims are rather too wide to be substantiated. The Lanhoffer dynamo when used as a motor-generator or constant-current transformer is not novel, at any rate in this country, as the idea originated many years ago with the Electric Construction Corporation, of Wolverhampton. They made a large number of machines of this type, which are employed at central stations on which continuous currents at high voltages are used. As an example, we may mention that such continuous-current transformers with a variable ratio are used by the Charing Cross and Strand Company. In these machines will be seen the exact arrangements illustrated in Fig. 2. It then remains to be considered what there is novel in the Lanhoffer dynamo beyond what we have referred to above? This, we think, is the claim for the exceedingly wide range in voltage for which a coefficient of 5 is claimed. By this we fancy that the authors mean that one of the dynamos in question would give its full current equally well at any voltage, say from 100 to 500. It will be noticed that no test figures are given to bear out this claim, and it is worth considering what feature in the machine allows the voltage to be reduced as low as 100 without sparking ensuing at the commutators. This, we believe, is not in the arrangement claimed, but to the fact as stated in the article that the fields have to be exceedingly heavy in order that the position of the brushes may be fixed. The sparking on the commutator is determined by, amongst other things, the field required to reverse the current in the section undergoing commutation. In this respect the Lanhoffer machine is no better off than an ordinary dynamo. The advantage of the two fields for a wide range is that by reversing the smaller field-magnet system, low voltages can be obtained without reducing the magnetisation of the iron of either machine to such a point as to be unstable. In fact, so far as sparking is concerned, the better way of getting a wide range of voltage with a constant current is to use a constant-current dynamo such as has been largely made by Messrs. Siemens Bros. and Co., and in which the voltage is varied by varying the position of the brushes round the commutator. The strength of field in the air-gap is then designed to be just that required to commutate the sections, so that the machine runs sparklessly for any position of the brushes. A dynamo of this kind could well be employed for charging in series the accumulators on the train referred to above.—Ed. *E. E.*

THE INAUGURATION OF THE ELECTRICITY SUPPLY AT POPLAR.

With considerable pomp and ceremony, the new works erected by the Poplar District Board of works for the supply of electrical energy to the districts of Poplar, Bow, and Bromley were formally opened on Monday last. These works are situated in Glaucus-street, Bromley, E., and the aristocracy of the neighbourhoods supplied turned up at the opening ceremony in their hundreds. The inauguration of the supply marks the practical completion of a very bold scheme, and one which will certainly tend vastly to the improvement and security of "Darkest London," at the same time securing to the poor of the

Digitized by Google

district better lighted streets than many to be found in the West-end of London. The undertaking has involved an expenditure of approximately £100,000, the work of instalment in connection with the same having been carried out according to the specifications of Mr. Alfred Blackman, M.I.E.E., under whose able supervision the works are happily destined to remain. It should be added that the necessary buildings have been erected by the direct employment of labour under the control of the Board's surveyor, Mr. Winter, who also designed the buildings.

The direct-current three-wire system has been adopted, with a supply at 230 volts for lighting purposes. Included in the first instalment of plant are two 320-b.h.p. engines running at 380 revolutions per minute, and coupled direct to two dynamos of 200 kw. capacity each; also two 165-b.h.p. engines running at 550 revolutions per minute, and coupled direct to two 100-kw. dynamos. Space is, however, left for considerable extensions. The arc lamps erected in the principal thoroughfares number about 200, and it is further intended to convert close upon 700 ordinary gas lamps by fitting them with incandescent electric lamps, whence it follows that Poplar should soon possess a very extensive system of street electric lighting. So far as supply to private consumers is concerned, arrangements have been made with the National Electric Wiring Company, Limited, for the free wiring of private premises, and current will be supplied on the maximum demand system, 5d. being charged for the first hour, 4d. for the second, and 3d. per unit afterwards for lighting, while 3d. and 1½d. will be charged for power. Already applications have been received for an equivalent of 5,000 8 c.p. lamps.

At the opening ceremony on Monday, Mr. J. Morton (chairman of the Board) presided, and it also fell to his lot to switch on the lighting of the buildings. Subsequently Mr. A. H. Valentine (chairman of the Electricity Committee) detailed the history and scope of the undertaking, and started one of the generating sets. Finally, Mr. Sydney Buxton, M.P. for the district, switched on the lamps in the public streets, at the same time declaring the supply formally inaugurated. He congratulated the district on the enterprise which had put put them in possesion of the supply. The Board, he considered, had always been equal to, if not ahead of, any similar body in London. Having had electric light in his house for 10 years, he recommended it as superior to gas in economy, convenience, and health. He was glad they had gone in for municipal enterprise in preference to private enterprise, and congratulated the expiring Board of Works on this, their great and final act, before giving place to the mayor, aldermen, and councillors of Poplar.

In the course of the further speechmaking, Mr. Blackman, the Board's electrical engineer, came in for a lot of merited praise for the energy which he has displayed in getting the plant installed. All circumstances considered, the works were found in a very advanced stage of completion, and time had also been found to make some elaborate special preparations for the opening ceremony, including some brilliant illuminating effects. We have little doubt but that the financial success of the undertaking will be rapidly assured under the able management of Mr. Blackman.

ELECTRICITY IN AN AMERICAN HOTEL.

The United States can truly boast of her fine hotels, the equipments and fittings of some of them being on such a grand and yet comfortable scale that they compare very favourably with even the best British and Continental residential hotels. Such a one is the Raleigh Hotel, of Washington, which ranks amongst the best hotels of the United States as regards its handsome and up-to-date equipments. These properties and fine appointments naturally led the public to patronise the hotel, with the result that it has become so popular that extensions have been necessary. A new wing, 11 storeys high, and of fireproof construction, has just been added, facing Twelfth-street. It is fitted throughout in the most luxurious style, and electrical power has been adopted wherever possible to take the place of less convenient machinery or hand power. This power is supplied from a central electric station in the basement of the new building. The plant is installed in an ideal place, being placed in a cellar excavated under the pavement of Twelfth-street. Here, being quite independent from the structure of the main building, all vibration and noises are completely isolated therefrom, and guests cannot detect when the plant is in operation. Using this cellar under the pavement also leaves the whole of the basement proper for other purposes. This vault extends for a length of 88·5ft., it is 19ft. wide for a distance of 21ft., and narrows down to 14ft. for the remaining. The average height of the ceiling is 9ft.; it varies with the gradients of the pavement. The roof of the vault is of I girders, with brickwork arches between. Over this is a layer of cement concrete, on which rests the pathway granolithic pavement, with a layer of tar and tarred paper between. The electrical equipment supplies lighting and the power for the older portions of the hotel as well as for the new extensions. The old belt-driven plant was abandoned, and the present up-to-date arrangement was designed and erected

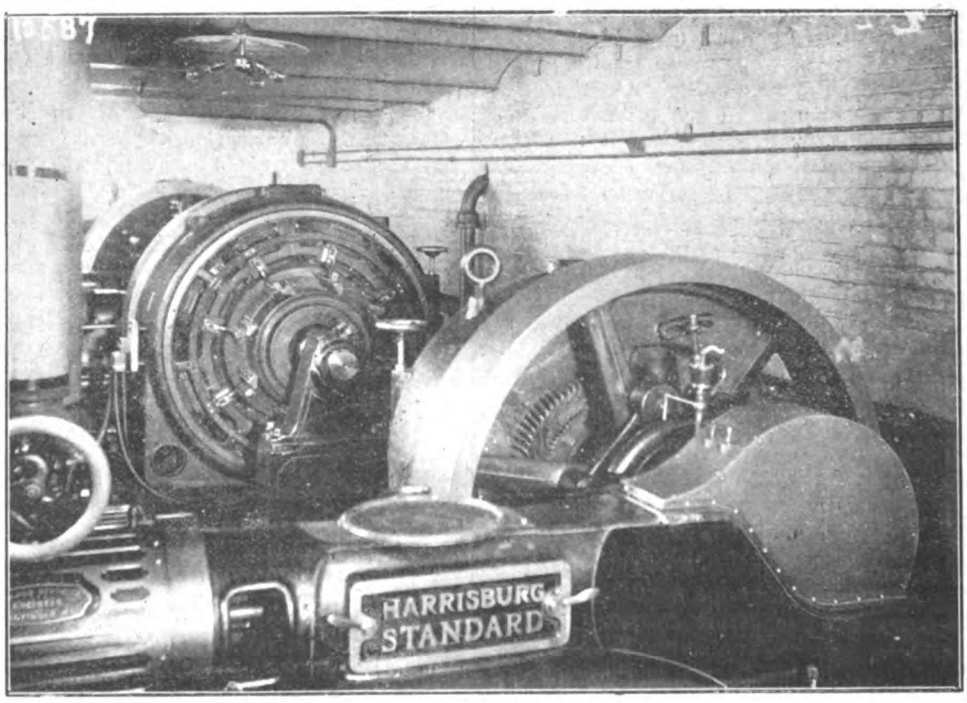

FIG I.—Two 100-kw. Westinghouse Direct-Current Generators, Raleigh Hotel, Washington, D.C.

by the Westinghouse Electric and Manufacturing Company to take up the whole of the electrical work.

The boiler-room is in the rear of the new addition; its floor is about 6ft. below the basement floor, and it contains two Geary boilers of about 200 h.p. each, working at 120lb. steam pressure per square inch. Steam is transmitted from the boiler-room to the engines in the power-room by an 8in. main. This main is, of course, well lagged, asbestos air-cell non-conducting material being used. In the widest part of the vault or power-room are placed side by side two 100-kw. Westinghouse direct-current generators yielding current at 125 volts pressure at a speed of 275 revolutions per minute. Each of these generators is direct coupled to a Harrisburg tandem compound non-condensing engine. Beyond these two sets are two others, a 75-kw. generator and a 25-kw. generator, each yielding current at a pressure of 125 volts, the former at a speed of 290 revolutions per minute, and the latter at a speed of 320 revolutions per minute. Each of these generators is coupled direct to a simple steam-engine. These generators have frequently been operated under overloads of 25 per cent. to 45 per cent., and have always behaved very well, carrying the overloads successfully. There being no head-room in the vault, it was not possible to instal a crane to raise the machine or engine parts when necessary for inspection or cleaning. On this account the pole-pieces of the generators are split vertically and set upon guide-plates, so that access may be had to the armature and field coils without removing the outboard bearing. The building is wired for about 4,000 incandescent lamps, running at 110 volts. Some most artistic effects have been produced in the parlours, writing-rooms, and dining-rooms, where the effect of clusters of different-coloured lamps with their reflection from the marble walls is particularly soft and pleasing.

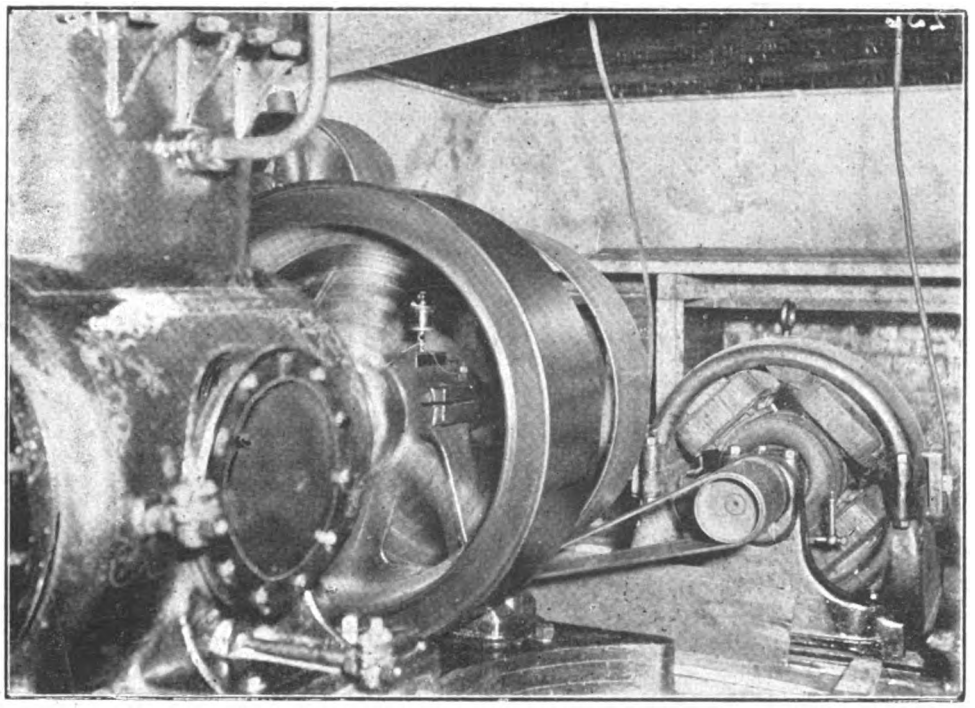

FIG. 2.—20-h.p. Westinghouse Direct-Current Motor operating Ice-Making Machine, Raleigh Hotel, Washington, D.C.

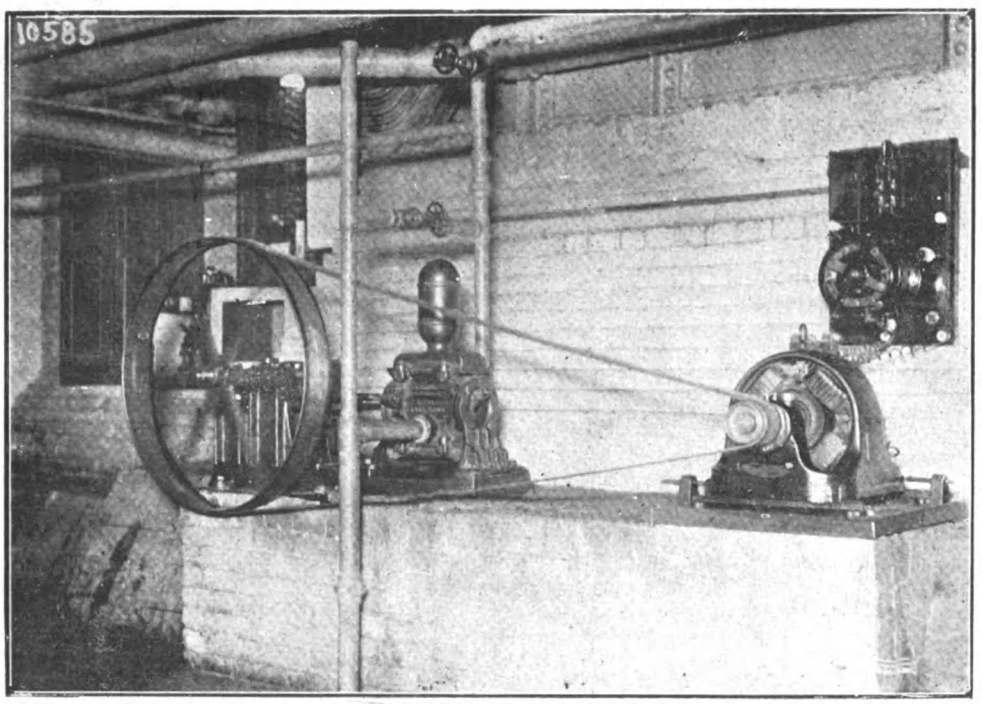

FIG. 3.—2-h.p. Westinghouse Motor operating Pump for Ammonia Condenser, Raleigh Hotel, Washington, D.C.

In addition to the lighting, power is used in various parts of the building to the extent of a total of about 60 h.p. As the places where this power is used were so widely scattered, steam driving was practically out of the question, and the conditions were such as to just prove

Digitized by Google

the great advantage of electricity for power distribution purposes. The electric motors, which are of the standard Westinghouse direct-current type, require very little attention, perform their work efficiently, and win universal praise. The largest share of the electrical motor power is taken up by the ice-making plant, which is capable of making 10 tons of ice in 24 hours. This plant requires three motors. A motor of 20 h.p., running at a speed of 600 revolutions per minute, operates the ammonia pump. The water for cooling the condensing coils is drawn by a Gould pump from an artesian well; this pump is driven by a 2-h.p. Westinghouse motor. A Gould triplex pump is driven by a 7·5-h.p. Westinghouse electric motor, running at a speed of 950 revolutions per minute. This pump is used for pumping brine for the ice plant.

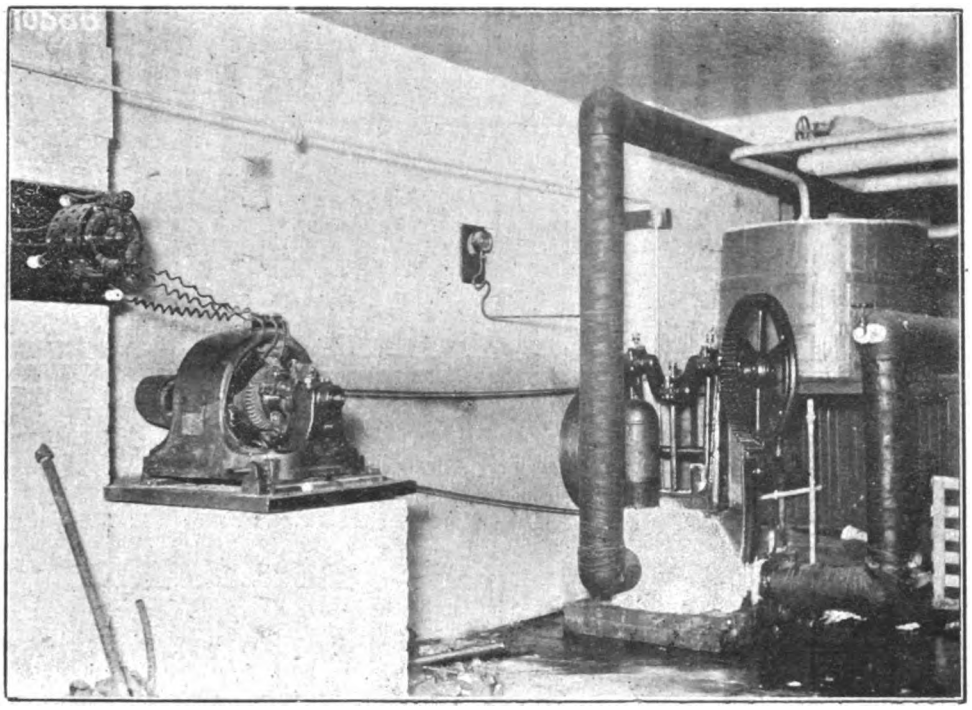

FIG. 4.—7½-h.p. Westinghouse Motor driving Brine-Circulating Pump, Raleigh Hotel, Washington, D.C.
